1. System and memory architecture

The system architecture of the GD32F20x series of devices that includes the ARM® Cortex™-M3 processor, bus architecture and memory organization will be described in the following sections. The Cortex™-M3 processor is a next generation processor core which offers many new features. Integrated and advanced features make the Cortex™-M3 processor suitable for market products that require microcontrollers with high performance and low power consumption. In brief, the Cortex™-M3 processor includes three AHB buses known as ICode, DCode and System buses. All memory accesses of the Cortex™-M3 processor are executed on the three buses according to the different purposes and the target memory spaces. The memory organization uses a Harvard architecture, pre-defined memory map and up to 4 GB of memory space, making the system flexible and extendable.

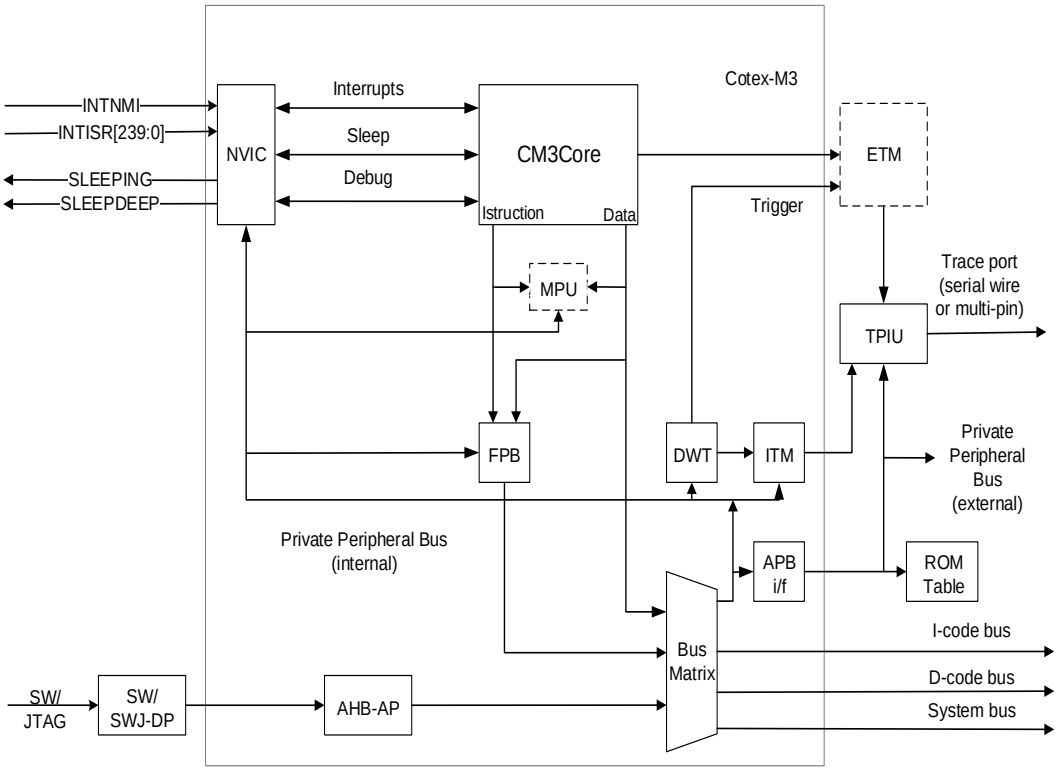
1.1. ARM Cortex-M3 processor

The Cortex™-M3 processor is a general-purpose 32-bit processor core, which is suitable for microcontrollers with high performance and low power consumption. It offers many new features such as Thumb-2 instruction sets, hardware divider, low latency interrupt respond time, atomic bit-banding access and multiple buses for simultaneous accesses. The Cortex™-M3 processor is based on the ARMv7 architecture and supports both Thumb and Thumb-2 instruction sets. Some system peripherals listed below are also provided by Cortex™-M3:

- Internal Bus Matrix, which is used to interconnect ICode bus, DCode bus, System bus, Private Peripheral Bus (PPB) and debug accesses (AHB-AP)
- Nested Vectored Interrupt Controller (NVIC)
- Flash Patch and Breakpoint (FPB)
- Data Watchpoint and Trace (DWT)
- Instrumentation Trace Macrocell (ITM)
- Serial Wire JTAG Debug Port (SWJ-DP)
- Trace Port Interface Unit (TPIU)
- Embedded Trace Macrocell (ETM)

Figure 1-1. Cortex™-M3 block diagram shows the Cortex™-M3 processor block diagram. For more information, refer to the ARM® Cortex™-M3 Technical Reference Manual.

Figure 1-1. Cortex™-M3 block diagram



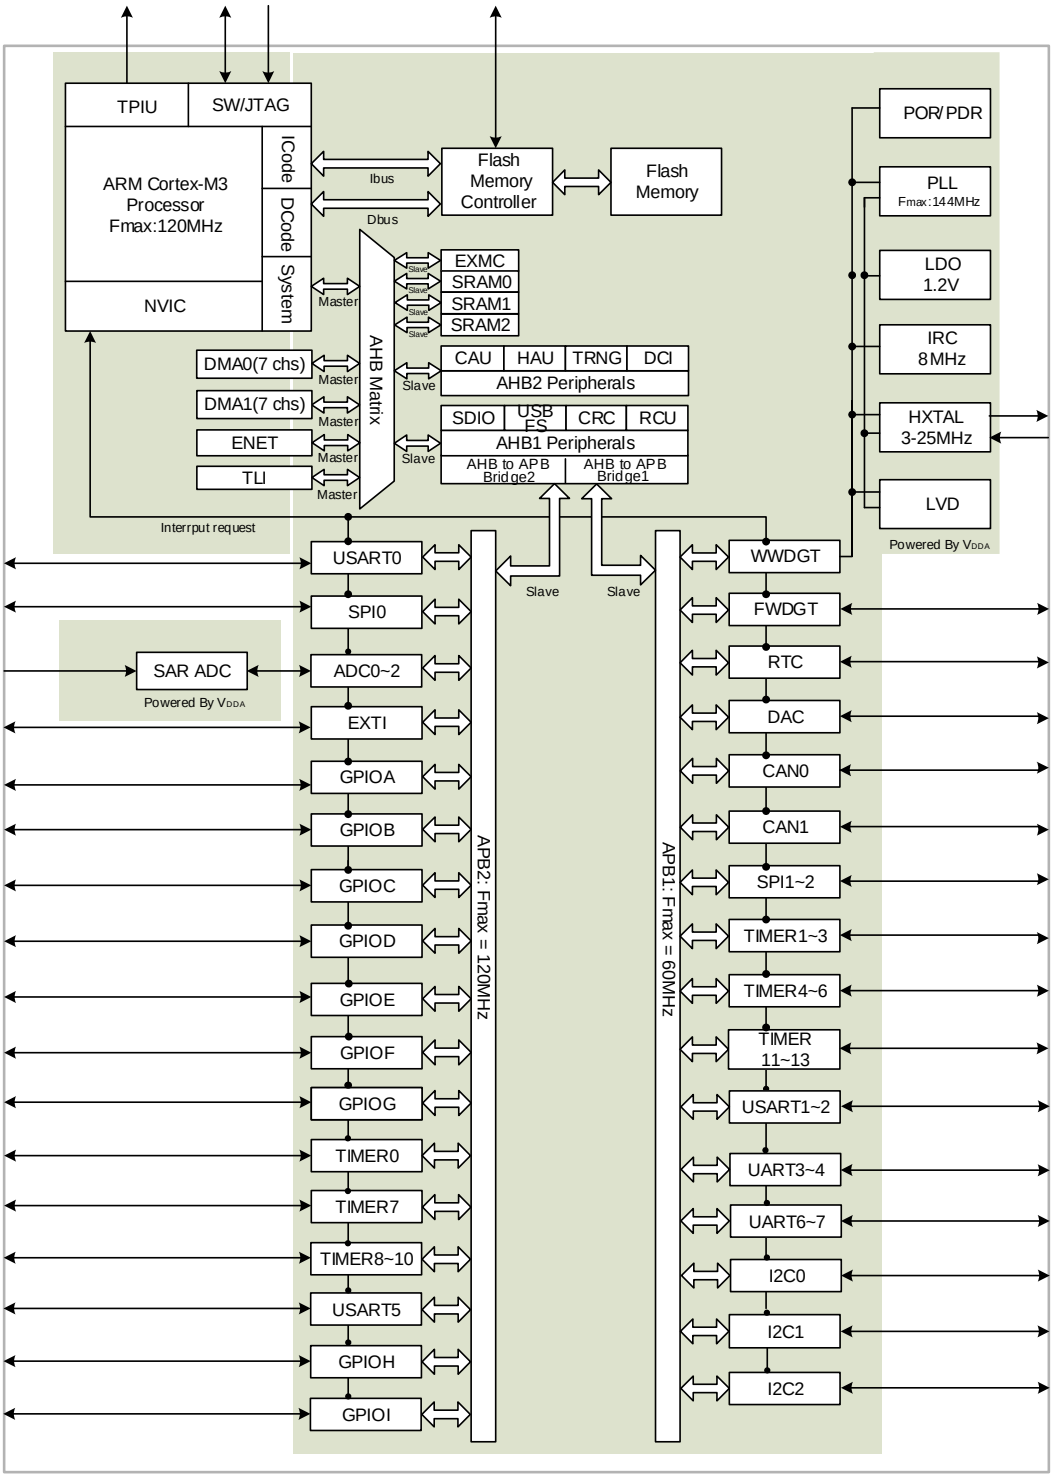
1.2. System architecture

The system architecture of the GD32F20x series is shown in the following figure. The AHB matrix based on AMBA 3.0 AHB-LITE is a multi-layer AHB, which enables parallel access paths between multiple masters and slaves in the system. There are seven masters on the AHB matrix, including ICode, DCode, system bus of the Cortex™-M3 core, DMA0, DMA1, Ethernet and TLI. The ICode bus is the instruction bus and also used for vector fetches from the Code region (0x0000 0000 ~ 0x1FFF FFFF) to the Cortex™-M3 core. The DCode bus is used for loading/ storing data and also for debug access of the Code region. Similarly, the System bus is used for instruction/vector fetches, data loading/storing and debugging access of the system regions. The System regions include the internal SRAM region, the external memory region and the Peripheral region. The AHB matrix consists of eight slaves, including ICode and DCode interfaces of the flash memory controller, internal SRAM0, SRAM1, SRAM2, external memory controller, system AHB1 and AHB2.

The AHB1 bus is connected to almost all the AHB peripherals, it includes two AHB-to-APB bus bridges which provide full synchronous connections between the system AHB and the two APB buses. The two APB buses are connected to all the APB peripherals. The maximum speed of the APB1 bus is 60 MHz, while the APB2 bus can operate at full speed (up to 120 MHz depending on the device).

These are interconnected using a multilayer AHB bus architecture as shown in ***Figure 1-2. GD32F20x Connectivity line series system architecture*** below:

Figure 1-2. GD32F20x Connectivity line series system architecture



1.3. Memory map

The ARM® Cortex™-M3 processor is structured in Harvard architecture which can use separate buses to fetch instructions and load/store data. The instruction code and data are both located in the same memory address space but in different address ranges. Program

memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space which is the maximum address range of the Cortex™-M3 since it has a 32-bit bus address width. Additionally, a pre-defined memory map is provided by the Cortex™-M3 processor to reduce the software complexity of repeated implementation of different device vendors. However, some regions are used by the ARM® Cortex™-M3 system peripherals. The following ***Table 1-1 Memory map of GD32F20x devices*** shows the memory map of the GD32F20x series of devices, including Code, SRAM, peripheral, and other pre-defined regions. Each peripheral of each series is allocated 1KB of space. This allows simplifying the address decoding for each peripheral. The APB1 peripherals are located at the address region from 0x4000 0000 to 0x4000 FFFF, while the APB2 peripherals are located from 0x4001 0000 to 0x4001 7FFF. The address region from 0x4001 8000 to 0x5003 FFFF is used by AHB1 peripherals. And the address region from 0x5004 0000 to 0x5FFF FFFF is used by AHB2 peripherals.

Table 1-1 Memory map of GD32F20x devices

Pre-defined Regions	Bus	Address	Peripherals
External RAM	AHB	0xC000 0000 – 0xDFFF FFFF	EXMC - SDRAM
		0xA000 0000 - 0xA000 0FFF	Reserved
		0x9000 0000 - 0x9FFF FFFF	EXMC - PC CARD
		0x7000 0000 - 0x8FFF FFFF	EXMC - NAND
		0x6000 0000 - 0x6FFF FFFF	EXMC - NOR/PSRAM/SQPI-PSRAM

		0x0800 0000 - 0x082F FFFF	Main Flash
		0x0030 0000 - 0x07FF FFFF	Aliased to Main Flash or Boot loader
		0x0010 0000 - 0x002F FFFF	
		0x0002 0000 - 0x000F FFFF	
		0x0000 0000 - 0x0001 FFFF	

1.3.1. Bit-banding

In order to reduce the time of read-modify-write operations, the Cortex™-M3 processor provides a bit-banding function to perform a single atomic bit operation. The memory map includes two bit-band regions. These occupy the SRAM and Peripherals respectively. These bit-band regions map each word in an alias region of memory to a bit in a bit-band region of memory.

A mapping formula shows how to reference each word in the alias region to a corresponding bit, or target bit, in the bit-band region. The mapping formula is:

bit_word_addr = bit_band_base + (byte_offset x 32) + (bit_number × 4).…….(1-1)

where:

- bit_word_addr is the address of the word in the alias memory region that maps to the targeted bit.
- bit_band_base is the starting address of the alias region.
- byte_offset is the number of the byte in the bit-band region that contains the targeted bit.
- bit_number is the bit position (0-7) of the targeted bit.

For example, to access bit 7 of address 0x2000 0200, the bit-band alias is:

bit_word_addr = 0x2200 0000 + (0x200 * 32) + (7 * 4) = 0x2200 401C……..(1-2)

Writing to address 0x2200 401C will cause bit 7 of address 0x2000 0200 change while a read to address 0x2200 401C will return 0x01 or 0x00 according to the value of bit 7 at the SRAM address 0x2000 0200.

1.3.2. On-chip SRAM memory

The GD32F20x series of devices contain up to 384 KB of on-chip SRAM which starts at the address 0x2000 0000. It supports byte, half-word (16 bits), and word (32 bits) accesses. On-chip SRAM is divided into three blocks, including SRAM0, SRAM1, and SRAM2. Each one owns a dedicated port connected to the AHB bus matrix. It means that they can be accessed simultaneously. The location and the capacity of them are shown in ***Table 1-2. Each block of SRAM***.

Table 1-2. Each block of SRAM

Block	Capacity	Location
SRAM0	112KB	0x2000 0000 ~ 0x2001 BFFF
SRAM1	16KB	0x2001 C000 ~ 0x2001 FFFF
SRAM2	256KB	0x2002 0000 ~ 0x2005 FFFF

1.3.3. On-chip Flash memory

The GD32F20x series of devices provide up to 3072 KB of on-chip flash memory. Read accesses can be performed 32 bits per cycle without any wait state. Besides, all of byte, half-word (16 bits) and word (32 bits) read accesses are supported. The flash memory can be programmed half-word (16 bits) or word (32 bits) at a time. Each page of the flash memory can be erased individually. The whole flash memory space except information blocks can be erased at a time.

1.4. Boot configuration

The devices of GD32F20x series provide three kinds of boot sources which can be selected

using the BOOT1 and BOOT0 pins. The values on the BOOT pins are latched on the 4th rising edge of SYSCLK after a reset. It is up to the user to set the BOOT1 and BOOT0 pins after a power-on reset or a system reset to select the required boot source. The details are shown in the following*Table 1-3. Boot modes*.

Table 1-3. Boot modes

Selected boot source	Boot mode selection pins	
	Boot1	Boot0
Main Flash Memory	x	0
System Memory	0	1
On-chip SRAM	1	1

After power-on sequence or a system reset, the ARM® Cortex™-M3 processor fetches the top-of-stack value from address 0x0000 0000 and the base address of boot code from 0x0000 0004 in sequence. Then, it starts executing code from the base address of boot code.

Due to the selected boot source, either the main flash memory (original memory space beginning at 0x0800 0000) or the system memory (original memory space beginning at 0x1FFF B000) is aliased in the boot memory space which begins at the address 0x0000 0000. When the on-chip SRAM whose memory space is beginning at 0x2000 0000 is selected as the boot source, in the application initialization code, you have to relocate the vector table in SRAM using the NVIC exception table and offset register.

The embedded boot loader is located in the System memory, which is used to reprogram the Flash memory. In GD32F20x devices, the boot loader can be activated through the USART0 interface.

GD32F2 MCU embedded bootloader supports multi interfaces to update the Flash memory.There will be one or two USART ports, and standard USB port can be used on GD32F205xx and GD32F207xx connectivity line products. The details are shown in the following*Table 1-4. Bootloader supported peripherals*.

Table 1-4. Bootloader supported peripherals

Products line	Products	Supported serial peripherals
Connectivity line	GD32F205xx	USART0(PA9 PA10) USART1(PD5 PD6) USB(PA9 PA10 PA11 PA12)
	GD32F207xx	USART0(PA9 PA10) USART1(PD5 PD6) USB(PA9 PA10 PA11 PA12)

1.5. Device electronic signature

Connectivity line devices (GD32F20X_CL) are GD32F205xx and GD32F207xx microcontrollers which the flash memory density ranges from 256 to 3072 Kbytes.

The device electronic signature contains memory size information and the 96-bit unique device ID. It is stored in the information block of the Flash memory. The 96-bit unique device ID is unique for any device. It can be used as serial numbers, or part of security keys, etc.

1.5.1. Memory size information

Base address: 0x1FFF F7E0
The value is factory programmed and can never be altered by user.

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRAM_SIZE [15:0]															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLASH_SIZE [15:0]															
r															

Bits	Fields	Descriptions
15:0	SRAM_ SIZE[15:0]	SRAM memory size The value indicates the SRAM memory size of the device in Kbytes. Example: 0x0020 indicates 32 Kbytes.
15:0	FLASH_SIZE[15:0]	Flash memory size The value indicates the Flash memory size of the device in Kbytes. Example: 0x0020 indicates 32 Kbytes.

1.5.2. Unique device ID (96 bits)

Base address: 0x1FFF F7E8
The value is factory programmed and can never be altered by user.

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UNIQUE_ID[31:16]															
r															

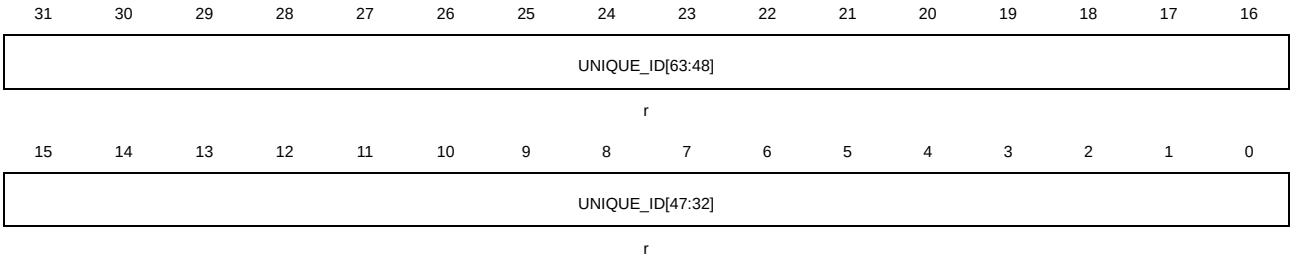
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UNIQUE_ID[15:0]															
r															

Bits	Fields	Descriptions
31:0	UNIQUE_ID[31:0]	Unique device ID

15:0	UNIQUE_ID[31:16]	This field value is reserved for a future feature

Address offset: 0x04

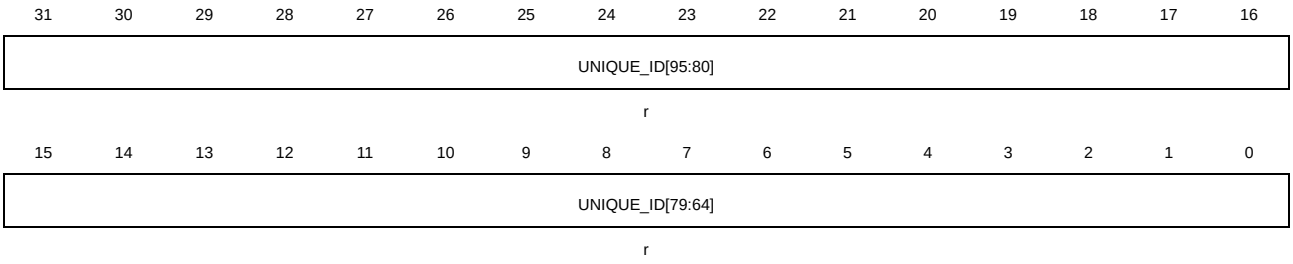
The value is factory programmed and can never be altered by user.



Bits	Fields	Descriptions
31:0	UNIQUE_ID[63:32]	Unique device ID

Address offset: 0x08

The value is factory programmed and can never be altered by user.

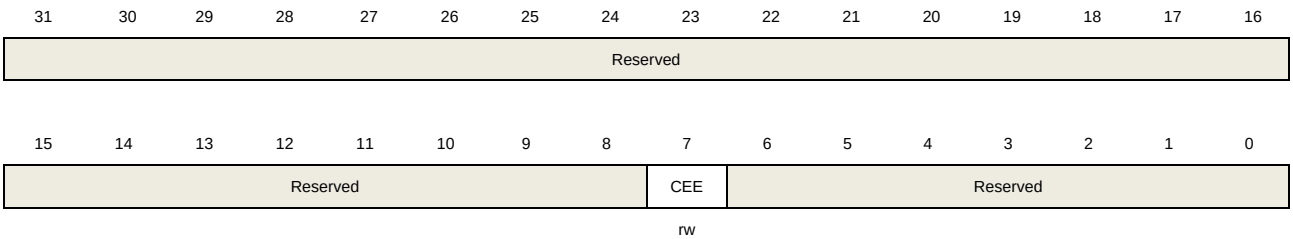


Bits	Fields	Descriptions
31:0	UNIQUE_ID[95:64]	Unique device ID

1.6. System configuration registers

Base address: 0x4002 103C

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value
7	CEE	Code execution efficiency 0: Default code execution efficiency 1: Code execution efficiency enhancement
6:0	Reserved	Must be kept at reset value

Note: Only bit[7] can be read-modify-write, other bits are not permitted.

2. Flash memory controller (FMC)

2.1. Overview

The flash memory controller, FMC, provides all the necessary functions for the on-chip flash memory. There is no waiting time while CPU executes instructions stored in the first 384K(in case that flash size equal to 256K or 512K, all memory is no waiting time) bytes of the flash . It also provides page erase, mass erase, and word/half-word program operations for flash memory.

2.2. Characteristics

- Up to 3072KB of on-chip flash memory for instruction and data.
- No waiting time within first 384K bytes when CPU executes instructions (in case that flash size equal to 256K or 512K, all memory is no waiting time). A long delay when CPU fetches the instructions out of the range.
- 2 banks adopted for GD32F20x_CL with flash size more than 512KB. Bank0 is used for the first 512KB and bank1 is for the rest capacity.
- Only bank0 is adopted for GD32F20x_CL with flash no more than 512KB.
- The flash page size is 2KB for bank0, 4KB for bank1.
- Word/half-word programming, page erase and mass erase operation.
- 16B option bytes block for user application requirements.
- Option bytes are uploaded to the option byte control registers on every system reset.
- Flash security protection to prevent illegal code/data access.
- Page erase/program protection to prevent unexpected operation.

2.3. Function overview

2.3.1. Flash memory architecture

For GD32F20x_CL with flash no more than 512KB, the page size is 2KB. For GD32F20x_CL with flash more than 512KB, bank0 is used for the first 512KB where the page size is 2KB. Bank1 is used for the rest capacity where the page size is 4KB. Each page can be erased individually.

The following ***Table 2-1. GD32F20x_CL*** shows the details of flash organization.

Table 2-1. GD32F20x_CL

Block		Name	Address Range	size (bytes)
Main Flash Block		Page 0	0x0800 0000 - 0x0800 07FF	2KB
		Page 1	0x0800 0800 - 0x0800 0FFF	2KB

Information Block	GD32F20x_CL	Boot loader area	0x1FFF B000- 0x1FFF F7FF	18KB
Option bytes Block		Option bytes	0x1FFF F800 - 0x1FFF F80F	16B

Note: The Information Block stores the boot loader. This block cannot be programmed or erased by user.

2.3.2. Read operations

The flash can be addressed directly as a common memory space. Any instruction fetch and the data access from the flash are through the IBUS or DBUS from the CPU.

2.3.3. Unlock the FMC_CTLx registers

After reset, the FMC_CTL0 register are not accessible in write mode, and the LK bit in FMC_CTL0 register is 1. An unlocking sequence consists of two write operations to the FMC_KEY0 register to open the access to the FMC_CTL0 register. The two write operations are writing 0x45670123 and 0xCDEF89AB to the FMC_KEY0 register. After the two write operations, the LK bit in FMC_CTL0 register is reset to 0 by hardware. The software can lock the FMC_CTL0 again by setting the LK bit in FMC_CTL0 register to 1. Any wrong operations to the FMC_KEY0 will set the LK bit to 1, and lock FMC_CTL0 register, and lead to a bus error.

The OBPG bit and OBER bit in FMC_CTL0 are still protected even the FMC_CTL0 is unlocked. The unlocking sequence is two write operations, which are writing 0x45670123 and 0xCDEF89AB to FMC_OBKEY register. And then the hardware sets the OBWEN bit in FMC_CTL0 register to 1. The software can reset OBWEN bit to 0 to protect the OBPG bit and

OBER bit in FMC_CTL0 register again.

For the GD32F20x_CL with flash more than 512KB, the FMC_CTL0 register is used to configure the operations to bank0 and the option bytes block, while FMC_CTL1 register is used to configure the program and erase operations to bank1. The lock/unlock mechanism of FMC_CTL1 register is similar to FMC_CTL0 register. The unlock sequence should be written to FMC_KEY1 when unlocking FMC_CTL1.

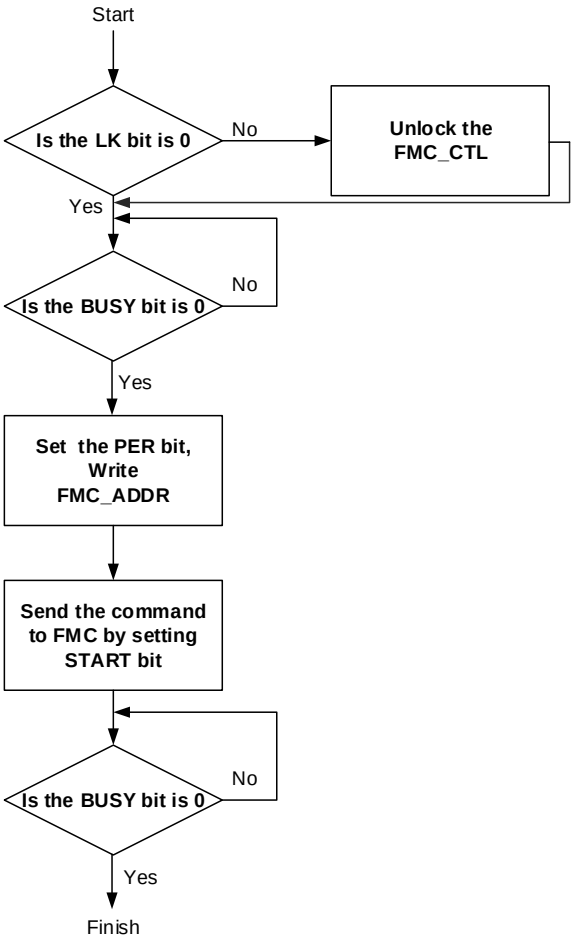
2.3.4. Page erase

The FMC provides a page erase function which is used to initialize the contents of a main flash memory page to a high state. Each page can be erased independently without affecting the contents of other pages. The following steps show the access sequence of the registers for a page erase operation.

- Unlock the FMC_CTLx registers if necessary.
- Check the BUSY bit in FMC_STATx registers to confirm that no flash memory operation is in progress (BUSY equals to 0). Otherwise, wait until the operation has finished.
- Set the PER bit in FMC_CTLx registers.
- Write the page absolute address (0x08XX XXXX) into the FMC_ADDRx registers.
- Send the page erase command to the FMC by setting the START bit in FMC_CTLx registers.
- Wait until all the operations have finished by checking the value of the BUSY bit in FMC_STATx registers.
- Read and verify the page by using a DBUS access if required.

When the operation is executed successfully, the ENDF in FMC_STATx registers is set, and an interrupt will be triggered by FMC if the ENDIE bit in the FMC_CTLx registers is set. Note that a correct target page address must be confirmed. Or the software may run out of control if the target erase page is being used to fetch codes or to access data. The FMC will not provide any notification when this occurs. Additionally, the page erase operation will be ignored on erase/program protected pages. In this condition, a flash operation error interrupt will be triggered by the FMC if the ERRIE bit in the FMC_CTLx registers is set. The software can check the WPERR bit in the FMC_STATx registers to detect this condition in the interrupt handler. The following ***Figure 2-1. Process of page erase operation*** shows the page erase operation flow.

Figure 2-1. Process of page erase operation



For the GD32F20x_CL with flash more than 512KB, FMC_STAT0 reflects the operation status of bank0, and FMC_ STAT1 reflects the operation status of bank1. The page erase procedure applied to bank1 is similar to the procedure applied to bank0. Especially, when erasing page in bank1 under security protection, the address should not only be written to FMC_ADRR1 but also to FMC_ADDR0.

2.3.5. Mass erase

The FMC provides a complete erase function which is used to initialize the main flash block contents. This erase can affect only on bank0 by setting MER bit to 1 in the FMC_CTL0 register, or only on bank1 by setting MER bit to 1 in the FMC_CTL1 register, or on entire flash by setting MER bits to 1 in FMC_CTL0 register and FMC_CTL1 register. The following steps show the mass erase register access sequence.

- Unlock the FMC_CTLx registers if necessary.
- Check the BUSY bit in FMC_STATx registers to confirm that no flash memory operation is in progress (BUSY equals to 0). Otherwise, wait until the operation has finished.

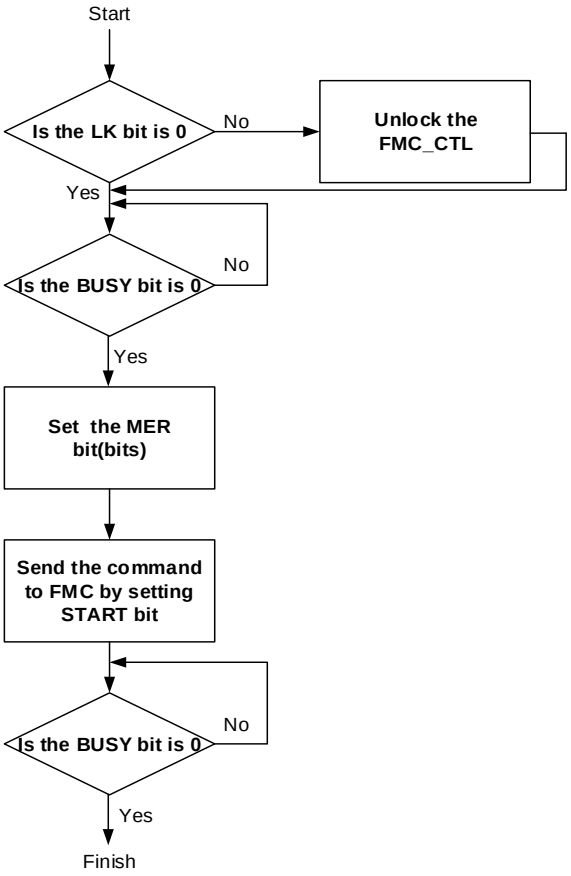
- Set MER bit in FMC_CTL0 register if erase bank0 only. Set MER bit in FMC_CTL1 register if erase bank1 only. Set MER bits in FMC_CTL0 register and FMC_CTL1 register if erase entire flash.
- Send the mass erase command to the FMC by setting the START bit in FMC_CTLx registers.
- Wait until all the operations have been finished by checking the value of the BUSY bit in FMC_STATx registers.
- Read and verify the flash memory by using a DBUS access if required.

When the operation is executed successfully, the ENDF in FMC_STATx registers is set, and an interrupt will be triggered by FMC if the ENDIE bit in the FMC_CTLx registers is set. Since all flash data will be modified to a value of 0xFFFF_FFFF, the mass erase operation can be implemented using a program that runs in SRAM or by using the debugging tool that accesses the FMC registers directly.

For the GD32F20x_CL with flash size more than 512KB, the mass erase procedure applied to bank1 is similar to the procedure applied to bank0.

The following ***Figure 2-2. Process of mass erase operation*** indicates the mass erase operation flow.

Figure 2-2. Process of mass erase operation



2.3.6. Main flash programming

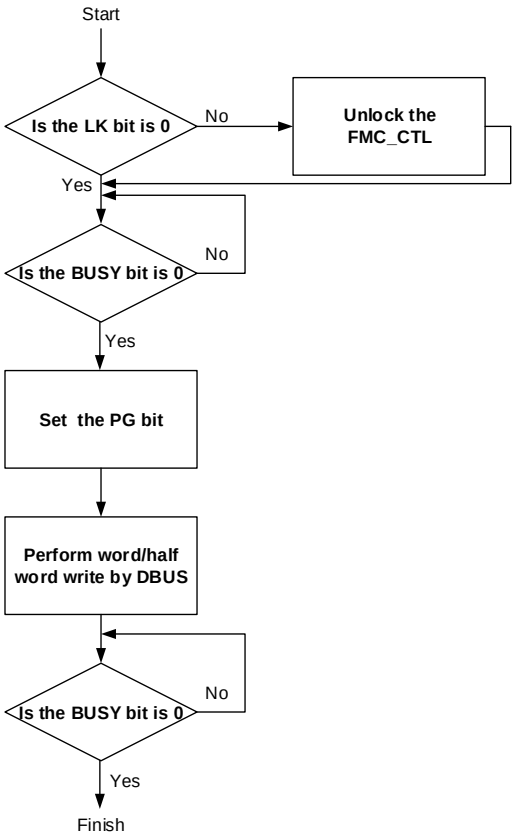
The FMC provides a 32-bit word/16-bit half word programming function which is used to modify the main flash memory contents. The following steps show the register access sequence of the word programming operation.

- Unlock the FMC_CTLx registers if necessary.
- Check the BUSY bit in FMC_STATx registers to confirm that no flash memory operation is in progress (BUSY equals to 0). Otherwise, wait until the operation has finished.
- Set the PG bit in FMC_CTLx registers.
- Write a 32-bit word/16-bit half word to desired absolute address (0x08XX XXXX) by DBUS.
- Wait until all the operations have been finished by checking the value of the BUSY bit in FMC_STATx registers.
- Read and verify the Flash memory by using a DBUS access if required.

When the operation is executed successfully, the ENDF in FMC_STATx registers is set, and an interrupt will be triggered by FMC if the ENDIE bit in the FMC_CTLx registers is set. Note

that the word/half word programming operation checks the address if it has been erased. If the address has not been erased, PGERR bit in the FMC_STATx registers will be set when programming the address except 0x0. Note that the PG bit must be set before the word/half word programming operation. Additionally, the program operation will be ignored on erase/program protected pages and WPERR bit in FMC_STATx is set. In these conditions, a flash operation error interrupt will be triggered by the FMC if the ERRIE bit in the FMC_CTLx registers is set. The software can check the PGERR bit or WPERR bit in the FMC_STATx registers to detect which condition occurred in the interrupt handler. The following ***Figure 2-3. Process of word program operation*** displays the word programming operation flow.

Figure 2-3. Process of word program operation



For the GD32F20x_CL with flash more than 512KB, the program procedure applied to bank1 is similar to the procedure applied to bank0.

Note: Reading the flash should be avoided when a program/erase operation is ongoing in the same bank. And flash memory accesses failed if the CPU enters the power saving modes.

2.3.7. Option bytes Erase

The FMC provides an erase function which is used to initialize the option bytes block in flash. The following steps show the erase sequence.

- Unlock the FMC_CTL0 register if necessary.
- Check the BUSY bit in FMC_STAT0 register to confirm that no Flash memory operation is in progress (BUSY equal to 0). Otherwise, wait until the operation has finished.
- Unlock the option bytes operation bits in FMC_CTL0 register if necessary.
- Wait until OBWEN bit is set in FMC_CTL0 register.
- Set OBER bit in FMC_CTL0 register.
- Send the option bytes erase command to the FMC by setting the START bit in FMC_CTL0 register.
- Wait until all the operations have been finished by checking the value of the BUSY bit in FMC_STAT0 register.
- Read and verify the Flash memory by using a DBUS access if required.

When the operation is executed successful, the ENDF in FMC_STAT0 register is set, and an interrupt will be triggered by FMC if the ENDIE bit in the FMC_CTL0 register is set.

2.3.8. Option bytes modify

The FMC provides an erase and then program function which is used to modify the option bytes block in flash. There are 8 pairs of option bytes. The MSB is the complement of the LSB in each pair. And when the option bytes are modified, the MSB is generated by FMC automatically, not the value of input data. The following steps show the erase sequence.

- Unlock the FMC_CTL0 register if necessary.
- Check the BUSY bit in FMC_STAT0 register to confirm that no Flash memory operation is in progress (BUSY equals to 0). Otherwise, wait until the operation has finished.
- Unlock the option bytes operation bits in FMC_CTL0 register if necessary.
- Wait until OBWEN bit is set in FMC_CTL0 register
- Set the OBPG bit in FMC_CTL0 register.
- A 32-bit word/16-bit half word write at desired address by DBUS.
- Wait until all the operations have been finished by checking the value of the BUSY bit in FMC_STAT0 register.
- Read and verify the Flash memory by using a DBUS access if required.

When the operation is executed successfully, the ENDF in FMC_STAT0 register is set, and an interrupt will be triggered by FMC if the ENDIE bit in the FMC_CTL0 register is set. Note that the word/half word programming operation needs to check whether the address has been erased or not. If the address has not been erased, PGERR bit in the FMC_STAT0 register will set when program the address except programming 0x0.

The modified option bytes only take effect after a system reset is generated.

2.3.9. Option bytes description

The option bytes block is reloaded to FMC_OBSTAT and FMC_WP registers after each system reset, and the option bytes take effect. The complement option bytes are the opposite of option bytes. When option bytes reload, if the complement option byte and option byte do not match, the OBERR bit in FMC_OBSTAT register is set, and the option byte is set to 0xFF. The OBERR bit is not set if both the option byte and its complement byte are 0xFF.The following ***Table 2-2. Option byte*** is the detail of option bytes.

Table 2-2. Option byte

Address	Name	Description
0x1fff f800	SPC	option byte Security Protection value 0xA5 : no security protection any value except 0xA5 : under security protection
0x1fff f801	SPC_N	SPC complement value
0x1fff f802	USER	[7:4]: reserved [3]: BB 0: boot from bank1 or bank0 if bank1 is void, when configured boot from main memory 1: boot from bank0, when configured boot from main memory [2]: nRST_STDBY 0: generate a reset instead of entering standby mode 1: no reset when entering standby mode [1]: nRST_DPSLP 0: generate a reset instead of entering Deep-sleep mode 1: no reset when entering Deep-sleep mode [0]: nWDG_HW 0: hardware free watchdog 1: software free watchdog
0x1fff f803	USER_N	USER complement value
0x1fff f804	DATA[7:0]	user defined data bit 7 to 0
0x1fff f805	DATA_N[7:0]	DATA complement value bit 7 to 0
0x1fff f806	DATA[15:8]	user defined data bit 15 to 8
0x1fff f807	DATA_N[15:8]	DATA complement value bit 15 to 8
0x1fff f808	WP[7:0]	Page Erase/Program Protection bit 7 to 0 0: protection active 1: unprotected
0x1fff f809	WP_N[7:0]	WP complement value bit 7 to 0
0x1fff f80a	WP[15:8]	Page Erase/Program Protection bit 15 to 8
0x1fff f80b	WP_N[15:8]	WP complement value bit 15 to 8
0x1fff f80c	WP[23:16]	Page Erase/Program Protection bit 23 to 16
0x1fff f80d	WP_N[23:16]	WP complement value bit 23 to 16

Address	Name	Description
0x1fff f80e	WP[31:24]	Page Erase/Program Protection bit 31 to 24 WP[30:24]: Each bit is related to 4KB flash protection, that means 2 pages for GD32F20x_ CL. Bit 0 configures the first 4KB flash protection, and so on. These bits totally controls the first 124KB flash protection. WP[31]: Bit 31 controls the protection of the rest flash memory.
0x1fff f80f	WP_N[31:24]	WP complement value bit 31 to 24

2.3.10. Page erase/program protection

The FMC provides page erase/program protection functions to prevent inadvertent operations on the Flash memory. The page erase or program will not be accepted by the FMC on protected pages. If the page erase or program command is sent to the FMC on a protected page, the WPERR bit in the FMC_STATx registers will then be set by the FMC. If the WPERR bit is set and the ERRIE bit is also set to 1 to enable the corresponding interrupt, then the Flash operation error interrupt will be triggered by the FMC to draw the attention of the CPU. The page protection function can be individually enabled by configuring the WP [31:0] bit field to 0 in the option bytes. If a page erase operation is executed on the option bytes block, all the Flash Memory page protection functions will be disabled. When WP in the option bytes is modified, a system reset followed is necessary.

2.3.11. Security protection

The FMC provides a security protection function to prevent illegal code/data access on the Flash memory. This function is useful for protecting the software/firmware from illegal users.

No protection: when setting SPC byte and its complement value to 0x5AA5, no protection performed. The main flash and option bytes block are accessible by all operations.

Under protection: when setting SPC byte and its complement value to any value except 0x5AA5, the security protection is performed. Note that a power reset should be followed instead of a system reset if the SPC modification is performed while the debug module is still connected to JTAG/SWD device. Under the security protection, the main flash can only be accessed by user code and the first 4KB flash is under erase/program protection. In debug mode, boot from SRAM or boot from boot loader mode, all operations to main flash is forbidden. If a read operation to main flash is in debug mode, boot from SRAM or boot from boot loader mode, a bus error will be generated. If a program/erase operation to main flash is in debug mode, boot from SRAM or boot from boot loader mode, the WPERR bit in FMC_STATx registers will be set. Option bytes block are accessible by all operations, which can be used to disable the security protection. If program back to no protection level by setting SPC byte and its complement value to 0x5AA5, a mass erase for main flash will be performed.

2.4. Register definition

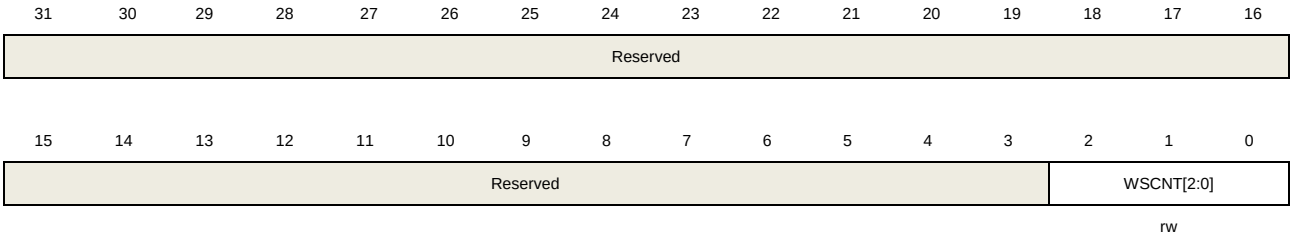
FMC start address: 0x4002 2000

2.4.1. Wait state register (FMC_WS)

Address offset: 0x00

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



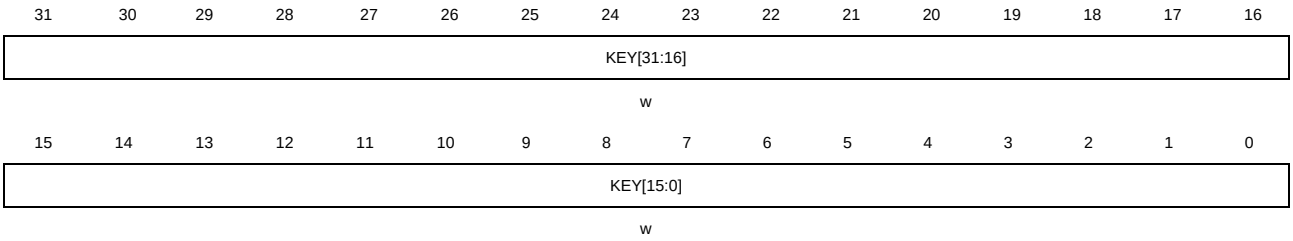
Bits	Fields	Descriptions
31:3	Reserved	Must be kept at reset value
2:0	WSCNT[2:0]	Wait state counter These bits is set and reset by software. The WSCNT valid when WSEN bit in FMC_WSEN is set. 000: 0 wait state added 001: 1 wait state added 010: 2 wait state added 011~111:reserved

2.4.2. Unlock key register 0(FMC_KEY0)

Address offset: 0x04

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:0	KEY[31:0]	FMC_CTL0 unlock key

These bits are only be written by software. Write KEY[31:0] with keys to unlock FMC_CTL0 register

2.4.3. Option byte unlock key register (FMC_OBKEY)

Address offset: 0x08

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OBKEY[31:16]															
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OBKEY[15:0]															
w															

Bits	Fields	Descriptions
31:0	OBKEY[31:0]	FMC_ CTL0 option bytes operation unlock key These bits are only be written by software. Write OBKEY[31:0] with keys to unlock option bytes command in FMC_CTL0 register.

2.4.4. Status register 0 (FMC_STAT0)

Address offset: 0x0C

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										ENDF	WPERR	Reserved	PGERR	Reserved	BUSY
										rc_w1	rc_w1		rc_w1		r

Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5	ENDF	End of operation flag bit When the operation executed successfully, this bit is set by hardware. The software can clear it by writing 1.
4	WPERR	Erase/Program protection error flag bit When erase/program on protected pages, this bit is set by hardware. The software

		can clear it by writing 1.
3	Reserved	Must be kept at reset value
2	PGERR	Program error flag bit When program to the flash while it is not 0xFFFF, this bit is set by hardware. The software can clear it by writing 1.
1	Reserved	Must be kept at reset value
0	BUSY	The flash busy bit When the operation is in progress, this bit is set to 1. When the operation is end or an error is generated, this bit is cleared.

2.4.5. Control register 0(FMC_CTL0)

Address offset: 0x10
Reset value: 0x0000 0080

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

			rw		rw	rw		rs	rs	rw	rw		rw	rw	rw

Bits	Fields	Descriptions
31:13	Reserved	Must be kept at reset value
12	ENDIE	End of operation interrupt enable bit This bit is set or cleared by software 0: no interrupt generated by hardware. 1: end of operation interrupt enable
11	Reserved	Must be kept at reset value
10	ERRIE	Error interrupt enable bit This bit is set or cleared by software 0: no interrupt generated by hardware. 1: error interrupt enable
9	OBWEN	Option byte erase/program enable bit This bit is set by hardware when right sequence written to FMC_OBKEY register. This bit can be cleared by software.
8	Reserved	Must be kept at reset value
7	LK	FMC_CTL0 lock bit

		This bit is cleared by hardware when right sequence written to FMC_KEY0 register. This bit can be set by software.
6	START	Send erase command to FMC bit This bit is set by software to send erase command to FMC. This bit is cleared by hardware when the BUSY bit is cleared.
5	OBER	Option bytes erase command bit This bit is set or clear by software 0: no effect 1: option byte erase command
4	OBPG	Option bytes program command bit This bit is set or clear by software 0: no effect 1: option bytes program command
3	Reserved	Must be kept at reset value
2	MER	Main flash mass erase for bank0 command bit This bit is set or cleared by software 0: no effect 1: main flash mass erase command for bank0
1	PER	Main flash page erase for bank0 command bit This bit is set or clear by software 0: no effect 1: main flash page erase command for bank0
0	PG	Main flash program for bank0 command bit This bit is set or clear by software 0: no effect 1: main flash program command for bank0

Note: This register should be reset after the corresponding flash operation completed.

2.4.6. Address register 0 (FMC_ADDR0)

Address offset: 0x14

Reset value: 0x0000 0000.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDR[31:16]

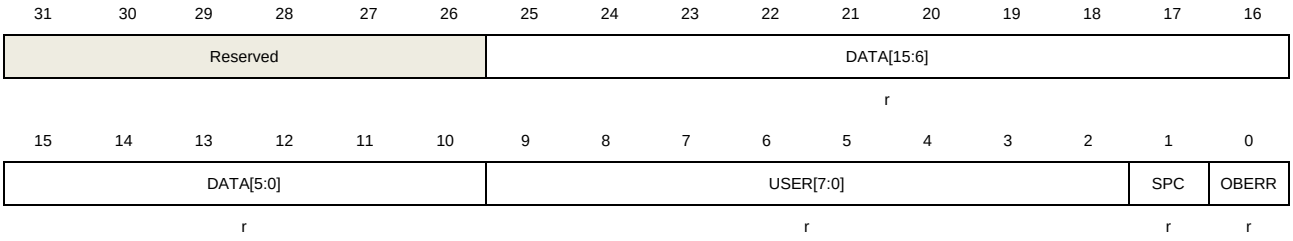
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR[15:0]															
W															

Bits	Fields	Descriptions
31:0	ADDR[31:0]	Flash erase/program command address bits These bits are configured by software. ADDR bits are the address of flash erase/program command

2.4.7. Option byte status register (FMC_OBSTAT)

Address offset: 0x1C
Reset value: 0x0XXX XXXX.

This register has to be accessed by word(32-bit)

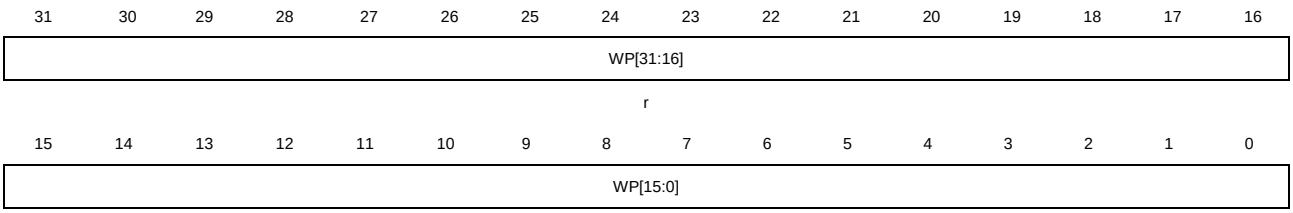


Bits	Fields	Descriptions
31:26	Reserved	Must be kept at reset value
25:10	DATA[15:0]	Store DATA of option bytes block after system reset.
9:2	USER[7:0]	Store USER of option bytes block after system reset.
1	SPC	Option bytes security protection code 0: no protection 1: protection
0	OBERR	Option bytes read error bit. This bit is set by hardware when the option bytes and its complement byte do not match, then the option bytes is set to 0xFF.

2.4.8. Erase/Program Protection register (FMC_WP)

Address offset: 0x20
Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)



r

Bits	Fields	Descriptions
31:0	WP[31:0]	Store WP of option bytes block after system reset

2.4.9. Unlock key register 1(FMC_KEY1)

Address offset: 0x44

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]

										rc_w1	rc_w1		rc_w1		r

Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5	ENDF	End of operation flag bit When the operation executed successfully, this bit is set by hardware. The software can clear it by writing 1.
4	WPERR	Erase/Program protection error flag bit

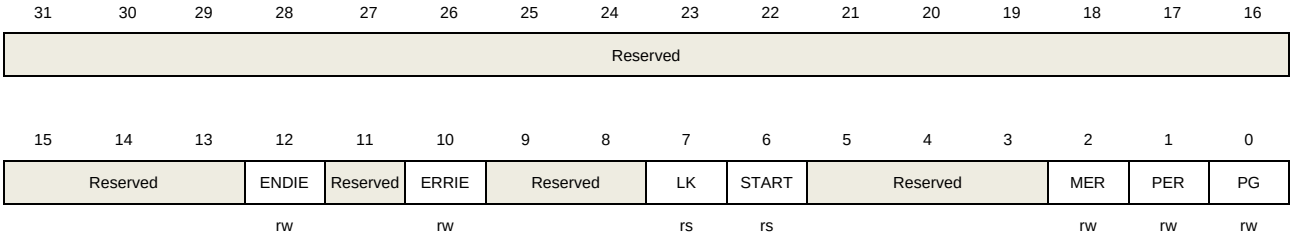
		When erase/program on protected pages, this bit is set by hardware. The software can clear it by writing 1.
3	Reserved	Must be kept at reset value
2	PGERR	Program error flag bit When program to the flash while it is not 0xFFFF, this bit is set by hardware. The software can clear it by writing 1.
1	Reserved	Must be kept at reset value
0	BUSY	The flash is busy bit. When the operation is in progress, this bit is set to 1. When the operation is end or an error is generated, this bit is cleared to 0.

2.4.11. Control register 1(FMC_CTL1)

Address offset: 0x50

Reset value: 0x0000 0080

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:13	Reserved	Must be kept at reset value
12	ENDIE	End of operation interrupt enable bit This bit is set or cleared by software 0: no interrupt generated by hardware. 1: end of operation interrupt enable
11	Reserved	Must be kept at reset value
10	ERRIE	Error interrupt enable bit This bit is set or cleared by software 0: no interrupt generated by hardware. 1: error interrupt enable
9:8	Reserved	Must be kept at reset value
7	LK	FMC_CTL1 lock bit This bit is cleared by hardware when right sequence written to FMC_KEY1 register.

		This bit can be set by software.
6	START	Send erase command to FMC bit This bit is set by software to send erase command to FMC. This bit is cleared by hardware when the BUSY bit is cleared.
5:3	Reserved	Must be kept at reset value
2	MER	Main flash mass erase for bank1 command bit This bit is set or cleared by software 0: no effect 1: main flash mass erase command for bank1
1	PER	Main flash page erase for bank1 command bit This bit is set or clear by software 0: no effect 1: main flash page erase command for bank1
0	PG	Main flash program for bank1 command bit This bit is set or clear by software 0: no effect 1: main flash program command for bank1

Note: This register should be reset after the corresponding flash operation completed.

2.4.12. Address register 1 (FMC_ADDR1)

Address offset: 0x54

Reset value: 0x0000 0000.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDR[31:16]

ADDR[15:0]															
W															

Bits	Fields	Descriptions
31:0	ADDR[31:0]	Flash erase/program command address bits These bits are configured by software. ADDR bits are the address of flash erase/program command.

2.4.13. Wait state enable register (FMC_WSEN)

Address offset: 0xFC

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Resrved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WSEN
															rw

Bits	Fields	Descriptions
31:1	Reserved	Must be kept at reset value
0	WSEN	FMC wait state enable This bit is set and reset by software. This bit also protected by the FMC_KEYx register. It is necessary to writing 0x45670123 and 0xCDEF89AB to the FMC_KEYx register. 0: no wait state added when fetch flash 1: wait state added when fetch flash

2.4.14. Product ID register (FMC_PID)

Address offset: 0x100

Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)

3. Power management unit (PMU)

3.1. Overview

The power consumption is regarded as one of the most important issues for the devices of GD32F20x series. Power management unit (PMU) provides three types of power saving modes, including Sleep mode, Deep-sleep mode and Standby mode. These modes reduce the power consumption and allow the application to achieve the best tradeoff among the conflicting demands of CPU operating time, speed and power consumption. For GD32F20x devices, there are three power domains, including V_{DD}/V_{DDA} domain, 1.2V domain, and Backup domain, as is shown in the following figure. The power of the V_{DD} domain is supplied directly by V_{DD}. An embedded LDO in the V_{DD}/V_{DDA} domain is used to supply the 1.2V domain power. A power switch is implemented for the Backup domain. It can be powered from the V_{BAT} voltage when the main V_{DD} supply is shut down.

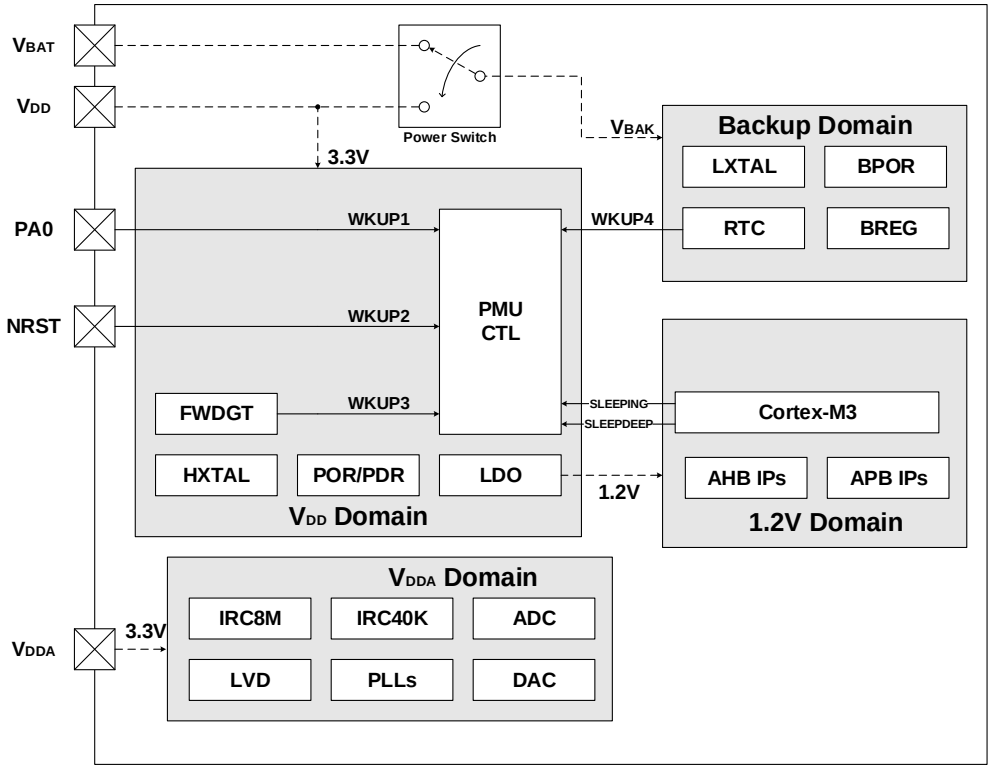
3.2. Characteristics

- Three power domains: V_{BAK} domain, V_{DD}/V_{DDA} domain and 1.2V power domain.
- Three power saving modes: Sleep mode, Deep-sleep mode and Standby mode.
- Internal Voltage regulator(LDO) supplies around 1.2V voltage source for 1.2V domain.
- Low Voltage Detector can issue an interrupt or event when the power is lower than a programmed threshold.
- Battery power (V_{BAT}) for Backup domain when V_{DD} is shut down.
- Select LDO output voltage to save energy consumption.

3.3. Function overview

Figure 3-1. Power supply overview provides details on the internal configuration of the PMU and the relevant power domains.

Figure 3-1. Power supply overview



3.3.1. Battery backup domain

The Backup domain is powered by the V_{DD} or the battery power source (V_{BAT}) selected by the internal power switch, and then the V_{BAK} pin drives Backup Domain. The Backup domain provides power to RTC unit, LXTAL oscillator, BPOR and BREG, and three pads, including PC13 to PC15. In order to ensure the content of the registers in Backup domain and the RTC work normally, when V_{DD} supply is shut down, V_{BAT} pin can be connected to an optional standby voltage supplied by a battery or by another source. The power switch is controlled by the Power Down Reset circuit in the V_{DD}/V_{DDA} domain. If no external battery is used in the application, it is recommended to connect V_{BAT} pin externally to V_{DD} pin with a 100nF external ceramic decoupling capacitor.

The Backup domain reset sources includes the Backup domain power-on-reset (BPOR) and the Backup Domain software reset. The BPOR signal forces the device to stay in the reset mode until V_{BAK} is completely powered up. Also the application software can trigger the Backup domain software reset by setting the BKPRST bit in the RCU_BDCTL register to reset the Backup domain.

The clock source of the Real Time Clock (RTC) circuit can be derived from the Internal 40KHz RC oscillator (IRC40K) or the Low Speed Crystal oscillator (LXTAL), or HXTAL clock divided by 128. When V_{DD} is shut down, only LXTAL is valid for RTC. Before entering the power saving mode by executing the WFI/WFE instruction, the Cortex™-M3 needs to setup the RTC

register with an expected wakeup time and enable the wakeup function so that it can achieve the RTC timer wakeup event. After entering the power saving mode for a certain amount of time, the RTC will wake up the device when the time match event occurs. The details of the RTC configuration and operation will be described in the ***Real-time Clock(RTC)***.

When the Backup domain is supplied by V_{DD} (V_{BAK} pin is connected to V_{DD}), the following functions are available:

- PC13 can be used as GPIO or RTC function pin described in the RTC chapter.
- PC14 and PC15 can be used as either GPIO or LXTAL Crystal oscillator pins.
- PI8 can be used as GPIO or RTC function pin described in the RTC chapter

When the Backup domain is supplied by V_{BAT} (V_{BAK} pin is connected to V_{BAT}), the following functions are available:

- PC13 can be used as RTC function pin described in the RTC chapter.
- PC14 and PC15 can be used as LXTAL Crystal oscillator pins only.
- PI8 can be used as RTC function pin described in the RTC chapter.

Note: Since PC13, PC14, PC15 are supplied through the Power Switch, which can only be obtained by a small current, the speed of GPIOs PC13 to PC15 should not exceed 2MHz when they are in output mode(maximum load: 30pF)

3.3.2. V_{DD}/V_{DDA} power domain

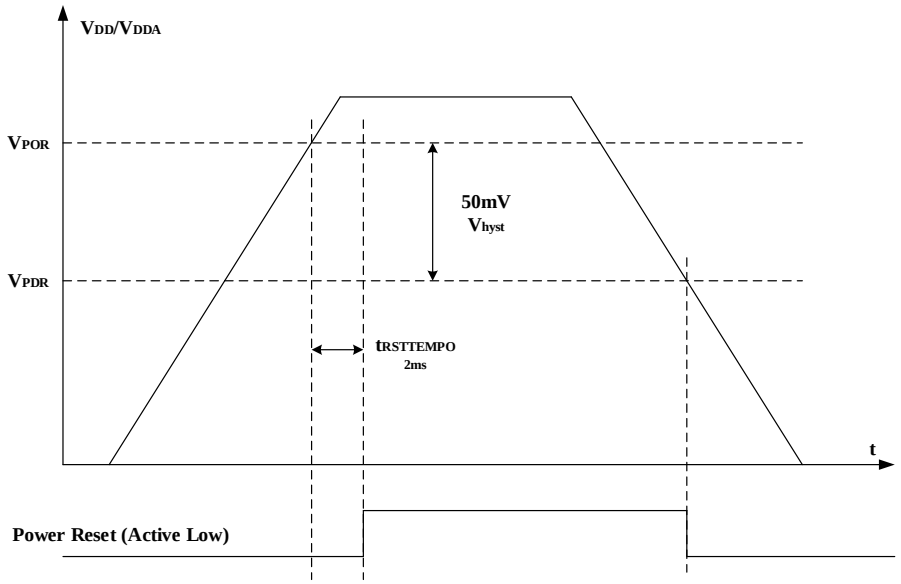
V_{DD}/V_{DDA} domain includes two parts: V_{DD} domain and V_{DDA} domain. V_{DD} domain includes HXTAL (High Speed Crystal oscillator), LDO (Voltage Regulator), POR/PDR (Power On/Down Reset), FWDGT (Free Watchdog Timer), all pads except PC13/PC14/PC15, etc. V_{DDA} domain includes ADC/DAC (AD/DA Converter), IRC8M (Internal 8MHz RC oscillator), IRC48M (Internal 48MHz RC oscillator at 48MHz frequency), IRC40K (Internal 40KHz RC oscillator), PLLs (Phase Locking Loop), LVD (Low Voltage Detector), etc.

V_{DD} domain

The LDO, which is implemented to supply power for the 1.2V domain, is always enabled after reset. It can be configured to operate in three different status, including in the Sleep mode (full power on), in the Deep-sleep mode (on or low power), and in the Standby mode (power off).

The POR/PDR circuit is implemented to detect V_{DD}/V_{DDA} and generate the power reset signal which resets the whole chip except the Backup domain when the supply voltage is lower than the specified threshold. ***Figure 3-2. Waveform of the POR/PDR*** shows the relationship between the supply voltage and the power reset signal. V_{POR}, which typical value is 2.40V, indicates the threshold of power on reset, while V_{PDR}, which typical value is 2.35V, means the threshold of power down reset. The hysteresis voltage (V_{hyst}) is around 50mV.

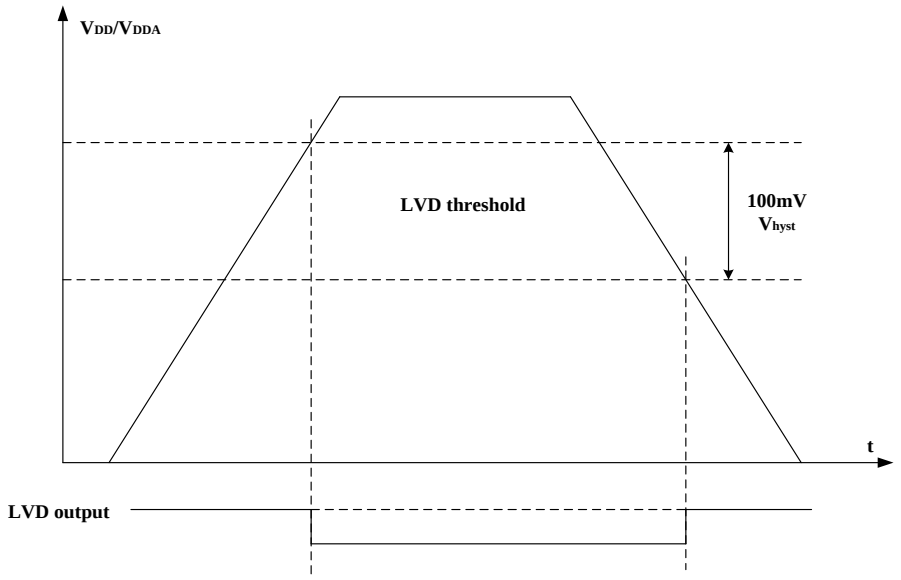
Figure 3-2. Waveform of the POR/PDR



V_{DDA} domain

The LVD is used to detect whether the V_{DD}/V_{DDA} supply voltage is lower than a programmed threshold selected by the LVDT[2:0] bits in the Power control register(PMU_CTL). The LVD is enabled by setting the LVDEN bit. The LVDF bit, which in the Power status register(PMU_CS), indicates if V_{DD}/V_{DDA} is higher or lower than the LVD threshold. This event is internally connected to the EXTI line 16 and can generate an interrupt if it is enabled through the EXTI registers. ***Figure 3-3. Waveform of the LVD threshold*** shows the relationship between the LVD threshold and the LVD output (LVD interrupt signal depends on EXTI line 16 rising or falling edge configuration). The following figure shows the relationship between the supply voltage and the LVD signal. The hysteresis voltage (V_{hyst}) is 100mV.

Figure 3-3. Waveform of the LVD threshold



Generally, digital circuits are powered by V_{DD}, while most of analog circuits are powered by V_{DDA}. To improve the ADC and DAC conversion accuracy, the independent power supply V_{DDA} is implemented to achieve better performance of analog circuits. V_{DDA} can be externally connected to V_{DD} through the external filtering circuit that avoids noise on V_{DDA}, and V_{SSA} should be connected to V_{SS} through the specific circuit independently. If V_{DDA} is different from V_{DD}, V_{DDA} must always be higher, but the voltage difference should not exceed 0.2V.

To ensure a high accuracy on low voltage ADC and DAC, the separate external reference voltage on V_{REF} should be connected to ADC/DAC pins. According to the different packages, V_{REF+} pin must be connected to V_{DDA} pin, V_{REF-} pin must be connected to V_{SSA} pin. The V_{REF+} pin is only available on no less than 100-pin packages, or else the V_{REF+} pin is not available and internally connected to V_{DDA}. The V_{REF-} pin is only available on no less than 100-pin packages, or else the V_{REF-} pin is not available and internally connected to V_{SSA}.

3.3.3. 1.2V power domain

The main function of 1.2V power domain includes Cortex™-M3 logic, AHB/APB peripherals, the APB interfaces for the Backup domain and the V_{DD}/V_{DDA} domain, etc. Once the 1.2V is powered up, the POR will generate a reset sequence on the 1.2V power domain. If need to enter the expected power saving mode, the associated control bits must be configured. Then, once a WFI (Wait for Interrupt) or WFE (Wait for Event) instruction is executed, the device will enter an expected power saving mode which will be discussed in the following section.

3.3.4. Power saving modes

After a system reset or a power reset, the GD32F20x MCU operates at full function and all power domains are active. Users can achieve lower power consumption through slowing down the system clocks (HCLK, PCLK1, PCLK2) or gating the clocks of the unused peripherals. Besides, three power saving modes are provided to achieve even lower power consumption, they are Sleep mode, Deep-sleep mode, and Standby mode.

Sleep mode

The Sleep mode is corresponding to the SLEEPING mode of the Cortex™-M3. In Sleep mode, only clock of Cortex™-M3 is off. To enter the Sleep mode, it is only necessary to clear the SLEEPDEEP bit in the Cortex™-M3 System Control Register, and execute a WFI or WFE instruction. If the Sleep mode is entered by executing a WFI instruction, any interrupt can wake up the system. If it is entered by executing a WFE instruction, any wakeup event can wake up the system (If SEVONPEND is 1, any interrupt can wake up the system, refer to Cortex-M3 Technical Reference Manual). The mode offers the lowest wakeup time as no time is wasted in interrupt entry or exit.

According to the SLEEPONEXIT bit in the Cortex™-M3 System Control Register, there are two options to select the Sleep mode entry mechanism.

- Sleep-now: if the SLEEPONEXIT bit is cleared, the MCU enters Sleep mode as soon as

WFI or WFE instruction is executed.

- Sleep-on-exit: if the SLEEPONEXIT bit is set, the MCU enters Sleep mode as soon as it exits from the lowest priority ISR.

Deep-sleep mode

The Deep-sleep mode is based on the SLEEPDEEP mode of the Cortex™-M3. In Deep-sleep mode, all clocks in the 1.2V domain are off, and all of IRC8M, HXTAL and PLLs are disabled. The contents of SRAM and registers are preserved. The LDO can operate normally or in low power mode depending on the LDOLP bit in the PMU_CTL register. Before entering the Deep-sleep mode, it is necessary to set the SLEEPDEEP bit in the Cortex™-M3 System Control Register, and clear the STBMOD bit in the PMU_CTL register. Then, the device enters the Deep-sleep mode after a WFI or WFE instruction is executed. If the Deep-sleep mode is entered by executing a WFI instruction, any interrupt from EXTI lines can wake up the system. If it is entered by executing a WFE instruction, any wakeup event from EXTI lines can wake up the system (If SEVONPEND is 1, any interrupt from EXTI lines can wake up the system, refer to Cortex-M3 Technical Reference Manual). When exiting the Deep-sleep mode, the IRC8M is selected as the system clock. Notice that an additional wakeup delay will be incurred if the LDO operates in low power mode.

Note: In order to enter Deep-sleep mode smoothly, all EXTI line pending status (in the EXTI_PD register) and RTC Alarm must be reset. If not, the program will skip the entry process of Deep-sleep mode to continue to execute the following procedure.

Standby mode

The Standby mode is based on the SLEEPDEEP mode of the Cortex™-M3, too. In Standby mode, the whole 1.2V domain is power off, the LDO is shut down, and all of IRC8M, HXTAL and PLL are disabled. Before entering the Standby mode, it is necessary to set the SLEEPDEEP bit in the Cortex™-M3 System Control Register, and set the STBMOD bit in the PMU_CTL register, and clear WUF bit in the PMU_CS register. Then, the device enters the Standby mode after a WFI or WFE instruction is executed, and the STBF status flag in the PMU_CS register indicates that the MCU has been in Standby mode. There are four wakeup sources for the Standby mode, including the external reset from NRST pin, the RTC alarm, the FWDGT reset, and the rising edge on WKUP pin. The Standby mode achieves the lowest power consumption, but spends longest time to wake up. Besides, the contents of SRAM and registers in 1.2V power domain are lost in Standby mode. When exiting from the Standby mode, a power-on reset occurs and the Cortex™-M3 will execute instruction code from the 0x00000000 address.

Table 3-1. Power saving mode summary

Mode	Sleep	Deep-sleep	Standby
Description	Only CPU clock is off	1.All clocks in the 1.2V domain are off 2.Disable IRC8M, HXTAL	1.The 1.2V domain is power off 2.Disable IRC8M, HXTAL

Mode	Sleep	Deep-sleep	Standby
		and PLL	and PLL
LDO Status	On	On or in low power mode	Off
Configuration	SLEEPDEEP = 0	SLEEPDEEP = 1 STBMOD = 0	SLEEPDEEP = 1 STBMOD = 1, WURST=1
Entry	WFI or WFE	WFI or WFE	WFI or WFE
Wakeup	Any interrupt for WFI Any event (or interrupt when SEVONPEND is 1) for WFE	Any interrupt from EXTI lines for WFI Any event(or interrupt when SEVONPEND is 1) from EXTI for WFE	1.NRST pin 2.WKUP pin 3.FWDGT reset 4.RTC
Wakeup Latency	None	IRC8M wakeup time, LDO wakeup time added if LDO is in low power mode	Power on sequence

3.4. Register definition

PMU start address: 0x4000 7000

3.4.1. Control register (PMU_CTL)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by wakeup from Standby mode)

This register can be accessed by half-word(16-bit) or word(32-bit)

							rw						r	r	r

Bits	Fields	Descriptions
31:9	Reserved	Must be kept at reset value
8	WUPEN	WKUP Pin Enable 0: Disable WKUP pin function 1: Enable WKUP pin function If WUPEN is set before entering the power saving mode, a rising edge on the WKUP pin wakes up the system from the power saving mode. As the WKUP pin is active high, the WKUP pin is internally configured to input pull down mode. And set this bit will trigger a wakup event when the input is aready high.
7:3	Reserved	Must be kept at reset value
2	LVDF	Low Voltage Detector Status Flag 0: Low Voltage event has not occurred (V_{DD} is higher than the specified LVD threshold) 1: Low Voltage event occurred (V_{DD} is equal to or lower than the specified LVD threshold) **Note:** The LVD function is stopped in Standby mode.

1	STBF	Standby Flag 0: The device has not entered the Standby mode 1: The device has been in the Standby mode This bit is cleared only by a POR/PDR or by setting the STBRST bit in the PMU_CTL register
0	WUF	Wakeup Flag 0: No wakeup event has been received 1: Wakeup event occurred from the WKUP pin or the RTC wakeup event including RTC Tamper event, RTC alarm event，RTC Time Stamp event or RTC Wakeup This bit is cleared only by a POR/PDR or by setting the WURST bit in the PMU_CTL register

4. Backup registers (BKP)

4.1. Overview

The Backup registers are located in the Backup domain that remains powered-on by V_{BAT} even if V_{DD} power is shut down. The Backup registers have forty two 16-bit (84 bytes) registers that can be used to store and protect user application data. Wake-up action from Standby mode or system reset do not affect these registers.

In addition, the BKP registers can be used to implement the tamper detection, RTC calibration function and waveform detection.

After reset, any writing access to the registers in Backup domain is disabled, that is, the Backup registers and RTC cannot be written to access. In order to enable access to the Backup registers and RTC, the Power and Backup interface clocks should be enabled firstly by setting the PMUEN and BKPIEN bits in the RCU_APB1EN register, and writing access to the registers in Backup domain should be enabled by setting the BKPWEN bit in the PMU_CTL register.

4.2. Characteristics

- 84 bytes Backup registers which can keep data under power saving mode. If tamper event is detected, Backup registers will be reset
- The active level of Tamper source (PC13 and PI8) can be configured
- RTC Clock Calibration register provides RTC alarm and second output selection, and sets the calibration value
- Tamper control and status register (BKP_TPCS) can control tamper detection and waveform dectection with interrupt or event capability
- Two square waveform detection on PC13->PI8 or PC14->PC15

4.3. Function overview

4.3.1. RTC clock calibration

In order to improve the RTC clock accuracy, the MCU provides clock output calibration function. The RTC clock, or a clock with the frequency is f_{RTCCLK}/64, can be output on the PC13. It is enabled by setting the COEN bit in the BKP_OCTL register.

The calibration value is set by RCCV[6:0] in the BKP_OCTL register, and the calibration function can slow down the RTC clock by steps of 1000000/2^20 ppm.

4.3.2. Tamper0 detection

In order to protect the important user data, the MCU provides the tamper detection function, and it can be independently enabled on TAMPER0 pin (PC13) by setting corresponding TPEN0 bit in the BKP_TPCTL register. To prevent the tamper event from losing, the edge detection is logically ANDed with the TPEN0 bit, the result is used as tamper detection signal. So the tamper detection configuration should be set before enable TAMPER0 pin. When the tamper event is detected, the corresponding TEF0 bit in the BKP_TPCS register will be set. Tamper event can generate an interrupt if tamper interrupt is enabled. Any tamper event will reset all Backup data registers.

Note: When TPAL0 = 0/1, if the TAMPER0 pin is already high/low before it is enabled(by setting TPEN0 bit), an extra tamper event is detected although there was no rising/falling edge on the TAMPER0 pin after TPEN0 bit was set.

4.3.3. Tamper1 detection

In order to protect the important user data, the MCU provides the tamper detection function, and it can be independently enabled on TAMPER1 pin (PI8) by setting corresponding TPEN1 bit in the BKP_TPCTL register. To prevent the tamper event from losing, the edge detection is logically ANDed with the TPEN1 bit, the result is used as tamper detection signal. So the tamper detection configuration should be set before enable TAMPER1 pin. When the tamper event is detected, the corresponding TEF1 bit in the BKP_TPCS register will be set. Tamper event can generate an interrupt if tamper interrupt is enabled. Any tamper event will reset all Backup data registers.

Note: When TPAL1 = 0/1, if the TAMPER1 pin is already high/low before it is enabled(by setting TPEN1 bit), an extra tamper event is detected although there was no rising/falling edge on the TAMPER1 pin after TPEN1 bit was set.

16.1.1. Waveform detection

MCU provides two methods of square wave detection. Send a square waveform on PC13 if TPM1 bit is set or on PC14 if TPM2 bit is set. Receive and check square waveform on PI8 if TPM1 bit set or on PC15 if TPM2 bit is set. When the check result is wrong, the corresponding TEF0/TEF1 bit in the BKP_TPCS register will be set. Tamper event can generate an interrupt if tamper interrupt is enabled. Any tamper event will reset all Backup data registers.

Note: If enable the LXTAL, set TPM2 has no effect. If set TPM1, must set TPEN0 and TPEN1 to 0.

4.4. Register definition

BPK start address: 0x4000 6C00

4.4.1. Backup data register x (BKP_DATAx) (x= 0..41)

Address offset: 0x04 to 0x28, 0x40 to 0xBC
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA [15:0]															
rw															

Bits	Fields	Descriptions
15:0	DATA[15:0]	Backup data These bits are used for general purpose data storage. The contents of the BKP_DATAx register will remain even if the wake-up action from Standby mode or system reset or power reset.

4.4.2. RTC signal output control register (BKP_OCTL)

Address offset: 0x2C
Reset value: 0x0000

This register can be accessed by half-word(16-bit) or word(32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CALDIR	CCOSEL	Reserved				ROSEL	ASOEN	COEN	RCCV[6:0]						
rw	rw					rw	rw	rw	rw						

Bits	Fields	Descriptions
15	CALDIR	RTC clock calibration direction 0: Slowed down 1: Speed up
14	CCOSEL	RTC clock output selection 0: RTC clock div 64 1: RTC clock
13:10	Reserved	Must be kept at reset value
9	ROSEL	RTC output selection 0: RTC alarm pulse is selected as the RTC output

		1: RTC second pulse is selected as the RTC output This bit is reset only by a Backup domain reset.
8	ASOEN	RTC alarm or second signal output enable 0: Disable RTC alarm or second output 1: Enable RTC alarm or second output When enable, the TAMPER0 pin is used as RTC output. This bit is reset only by a Backup domain reset.
7	COEN	RTC clock calibration output enable 0: Disable RTC clock calibration output 1: Enable RTC clock Calibration output When enable, the TAMPER0 pin will output the RTC clock or RTC clock divided by 64. ASOEN has the priority over COEN. When ASOEN is set, the TAMPER0 pin will output the RTC alarm or second signal whether COEN is set or not. This bit is reset only by a POR/PDR.
6:0	RCCV[6:0]	RTC clock calibration value The value indicates how many clock pulses are ignored or added every 2^20 RTC clock pulses.

4.4.3. Tamper pin control register0 (BKP_TPCTL0)

Address offset: 0x30
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														TPAL0	TPEN0
														rw	rw

Bits	Fields	Descriptions
15:2	Reserved	Must be kept at reset value
1	TPAL0	TAMPER0 pin active level 0: The TAMPER0 pin is active high 1: The TAMPER0 pin is active low
0	TPEN0	TAMPER0 detection enable 0: The TAMPER0 pin is free for GPIO functions 1: The TAMPER0 pin is dedicated for the Backup Reset function. The active level on the TAMPER0 pin resets all data of the BKP_DATAx register.

4.4.4. Tamper control and status register (BKP_TPCS)

Address offset: 0x34

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIF1	TEF1	Reserved				TIF0	TEF0	TPIE1	TIR1	TER1	Reserved		TPIE0	TIR0	TER0
r	r					r	r	rw	w	w			rw	w	w

Bits	Fields	Descriptions
15	TIF1	Tamper1/waveform detect interrupt flag 0: No tamper1 interrupt occurred 1: A tamper1 interrupt occurred This bit is reset by writing 1 to the TIR1 bit or the TPIE1 bit being 0.
14	TEF1	Tamper1/waveform detect event flag 0: No tamper1 event occurred 1: A tamper1 event occurred This bit is reset by writing 1 to the TER1 bit.
13:10	Reserved	Must be kept at reset value
9	TIF0	Tamper0 interrupt flag 0: No tamper0 interrupt occurred 1: A tamper0 interrupt occurred This bit is reset by writing 1 to the TIR0 bit or the TPIE0 bit being 0.
8	TEF0	Tamper0 event flag 0: No tamper0 event occurred 1: A tamper0 event occurred This bit is reset by writing 1 to the TER0 bit.
7	TPIE1	Tamper1/waveform detect interrupt enable 0: Disable the tamper1 interrupt 1: Enable the tamper1 interrupt This bit is reset only by a system reset and wake-up from Standby mode.
6	TIR1	Tamper1/waveform detect interrupt reset 0: No effect 1: Reset the TIF1 bit This bit is always read as 1.
5	TER1	Tamper1/waveform detect event reset 0: No effect 1: Reset the TEF1 bit This bit is always read as 0.

4:3	Reserved	Must be kept at reset value
2	TPIE0	Tamper0 interrupt enable 0: Disable the tamper0 interrupt 1: Enable the tamper0 interrupt This bit is reset only by a system reset and wake-up from Standby mode.
1	TIR0	Tamper0 interrupt reset 0: No effect 1: Reset the TIF0 bit This bit is always read as 0.
0	TER0	Tamper0 event reset 0: No effect 1: Reset the TEF0 bit This bit is always read as 0.

4.4.5. Tamper pin control register1 (BKP_TPCTL1)

Address offset: 0x38

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TPM1	TPM2	Reserved				TPAL1	TPEN1	Reserved							
w	w					rw	rw								

Bits	Fields	Descriptions
15	TPM1	The first Waveform detection enable 0: No effect 1: Detect waveform of RTCCLK/64, need configure CCOSEL to 0, TPEN0, TPEN1 to 0 PC13 -> PI8
14	TPM2	The second Waveform detection enable 0: No effect 1: Detect waveform of RTCCLK/64, need configure CCOSEL to 0, TPEN0, TPEN1 to 0 PC14 -> PC15
13:10	Reserved	Must be kept at reset value
9	TPAL1	TAMPER1 pin active level 0: The TAMPER1 pin is active high 1: The TAMPER1 pin is active low

8	TPEN1	TAMPER1 detection enable 0: The TAMPER1 pin is free for GPIO functions 1: The TAMPER1 pin is dedicated for the Backup Reset function. The active level on the TAMPER1 pin resets all data of the BKP_DATAx register.
7:0	Reserved	Must be kept at reset value

5. Reset and clock unit (RCU)

5.1. Reset control unit (RCTL)

5.1.1. Overview

GD32F20x Reset Control includes three control modes: power reset, system reset and backup domain reset. The power reset, known as a cold reset, resets the full system except the Backup domain. The system reset resets the processor core and peripheral IP components except for the SW-DP controller and the Backup domain. The backup domain reset resets the Backup domain. The resets can be triggered by an external signal, internal events and the reset generators. More information about these resets will be described in the following sections.

5.1.2. Function overview

Power Reset

The Power reset is generated by either an external reset as Power On and Power Down reset (POR/PDR reset) or the internal reset generator when exiting Standby mode. The power reset sets all registers to their reset values except the Backup domain. The Power reset which active signal is low, it will be de-asserted when the internal LDO voltage regulator is ready to provide 1.2V power. The RESET service routine vector is fixed at address 0x0000_0004 in the memory map.

System Reset

A system reset is generated by the following events:

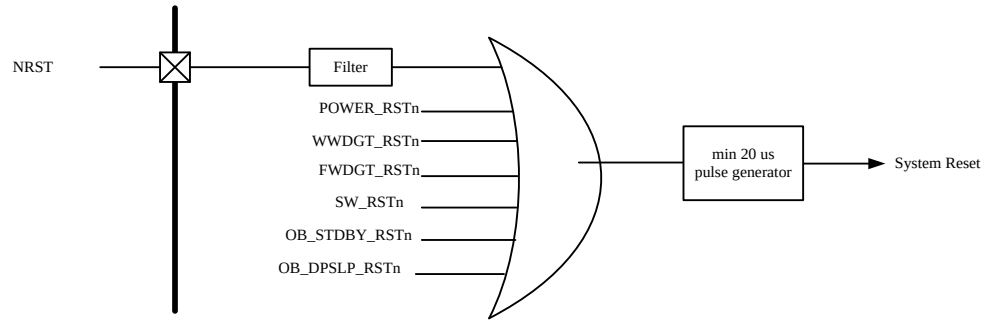
- A power reset (POWER_RSTn)
- A external pin reset (NRST)
- A window watchdog timer reset (WWDGT_RSTn)
- A free watchdog timer reset (FWDGT_RSTn)
- The SYSRESETREQ bit in Cortex™-M3 Application Interrupt and Reset Control Register is set (SW_RSTn)
- Reset generated when entering Standby mode and setting nRST_STDBY bit 0 in User Option Bytes (OB_STDBY_RSTn)
- Reset generated when entering Deep-sleep mode and setting nRST_DPSLP bit 0 in User Option Bytes (OB_DPSLP_RSTn)

A system reset resets the processor core and peripheral IP components except for the SW-

DP controller and the Backup domain.

A system reset pulse generator guarantees low level pulse duration of 20 μs for each reset source (external or internal reset).

Figure 5-1. The system reset circuit



Backup domain reset

A backup domain reset is generated by setting the BKPRST bit in the Backup domain control register or Backup domain power on reset (V_{DD} or V_{BAT} power on, if both supplies have previously been powered off).

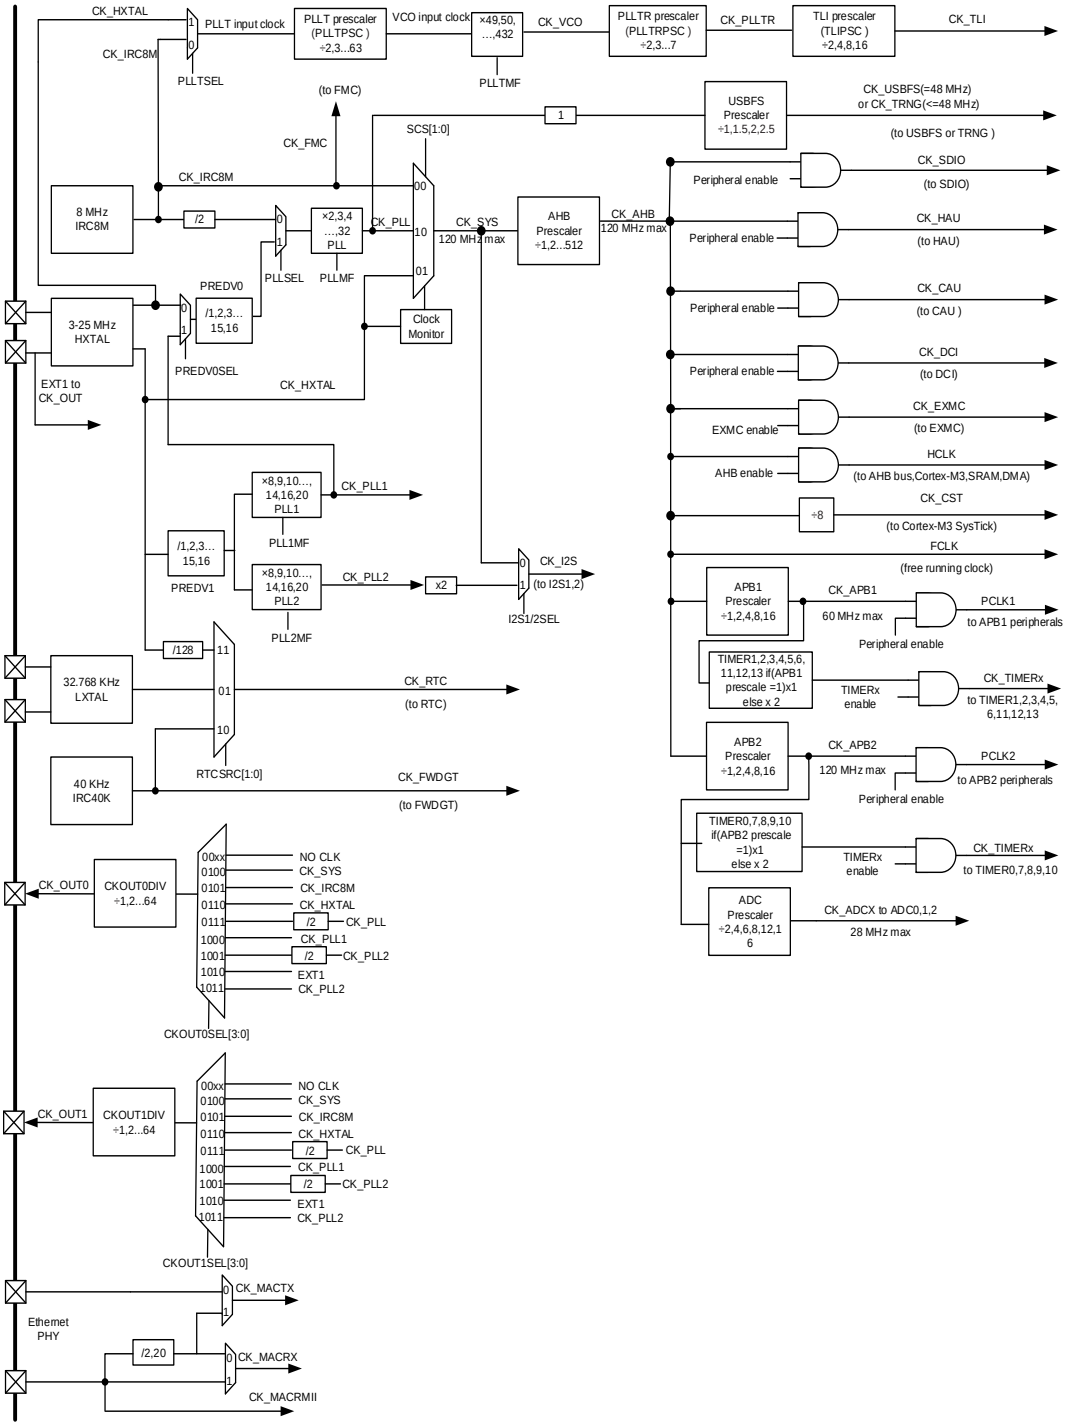
5.2. Clock control unit (CCTL)

5.2.1. Overview

The clock control unit provides a series of frequency clock functions. These include a Internal 8M RC oscillator (IRC8M), a High Speed crystal oscillator (HXTAL), a Low Speed Internal 40K RC oscillator (IRC40K), a Low Speed crystal oscillator (LXTAL), three Phase Lock Loop (PLL,PLL1 and PLL2), a HXTAL clock monitor, clock prescalers, clock multiplexers and clock gating circuitry.

The clocks of the AHB, APB and Cortex™-M3 are derived from the system clock (CK_SYS) the clock source of the system clock can choose IRC8M, HXTAL or PLL. The maximum operating frequency of the system clock (CK_SYS) can be up to 120 MHz. The Free Watchdog Timer has independent clock source (IRC40K), and Real Time Clock (RTC) uses the IRC40K, LXTAL or HXTAL/128 as its clock source.

Figure 5-2. Clock tree



The RCU controller of connectivity line devices has three PLLs(PLL, PLL1, PLL2) and can provide a variety of configuration of clock frequency to meet the needs of microcontrollers.

The frequency of AHB, APB2 and the APB1 domains can be configured by each prescaler. The maximum frequency of the AHB, APB2 and APB1 domains is 120 MHz/120 MHz/60 MHz. The RCU is used as the external clock of Cortex system Timer(SysTick) after the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or with the AHB clock (HCLK) by configuring the SysTick Control and Status Register.

The ADCs are clocked by the clock of APB2 divided by 2, 4, 6, 8, 12 or 16, which defined by ADCPSC in RCU_CFG0.

The TIMERs are clocked by the clock divided from CK_APB2 and CK_APB1. The frequency of TIMERs clock is equal to CK_APBx(APB prescaler is 1), twice the CK_APBx(APB prescaler is not 1).

The USBFS is clocked by PLL, divided by 1, 1.5, 2, 2.5 which select by USBFSPSC bit in configuration register 0 (RCU_CFG0).The USBFS clock must be 48MHz. These bits also control the random analog generator (TRNG) clock (≤48 MHz). The TRNG is also clocked by PLL, divided by 1, 1.5, 2, 2.5 which select by USBFSPSC bits.

The I2S is clocked by the clock of CK_SYS or PLL2*2 which defined by I2SxSEL bit in RCU_CFG1 register.

The ENET TX/RX are clocked by External PIN (ENET_TX_CLK / ENET_RX_CLK), which select by ENET_PHY_SEL bit in AFIO_PCF0 register.

The Ethernet MAC is clocked by the external PHY. If using the Ethernet module, it must keep the AHB clock frequency at least 25 MHz.

The RTC is clocked by LXTAL clock or IRC40K clock or HXTAL clock divided by 128 which select by RTCSRC bit in Backup Domain Control Register (RCU_BDCTL).

The FWDGT is clocked by IRC40K clock, which is forced on when FWDGT started.

5.2.2. Characteristics

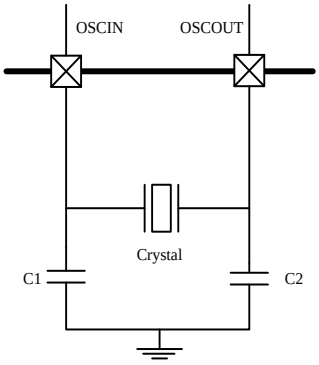
- 3 to 25 MHz High Speed crystal oscillator (HXTAL) .
- Internal 8 MHz RC oscillator (IRC8M).
- 32,768 Hz Low Speed crystal oscillator (LXTAL).
- Internal 40 KHz RC oscillator (IRC40K).
- PLL clock source can be HXTAL, IRC8M or PLL1.
- HXTAL clock monitor.

5.2.3. Function overview

High speed crystal oscillator (HXTAL)

The High speed crystal oscillator (HXTAL), which has a frequency range from 3 to 25 MHz, produces a highly accurate clock source for using as the system clock. A crystal with a specific frequency must be connected and located close to the two HXTAL pins. The external resistor and capacitor components connected to the crystal are necessary for proper oscillation.

Figure 5-3. HXTAL clock source



The HXTAL crystal oscillator can be switched on or off using the HXTALEN bit in the control register RCU_CTL. The HXTALSTB flag in control register RCU_CTL indicates if the high-speed external crystal oscillator is stable. When the HXTAL is powered up, it will not be released for use until this HXTALSTB bit is set by the hardware. This specific delay period is known as the oscillator “Start-up time”. As the HXTAL becomes stable, an interrupt will be generated if the related interrupt enable bit HXTALSTBIE in the interrupt register RCU_INT is set. At this point the HXTAL clock can be used directly as the system clock source or the PLL input clock.

Select external clock bypass mode by setting the HXTALBPS and HXTALEN bits in the control register RCU_CTL. The CK_HXTAL is equal to the external clock which drives the OSCIN pin.

Internal 8M RC oscillators (IRC8M)

The internal 8M RC oscillator, IRC8M, has a fixed frequency of 8 MHz and is the default clock source selection for the CPU when the device is powered up. The IRC8M oscillator provides a lower cost type clock source as no external components are required. The IRC8M RC oscillator can be switched on or off using the IRC8MEN bit in the control register RCU_CTL. The IRC8MSTB flag in the Control register RCU_CTL is used to indicate if the internal RC oscillator is stable. The start-up time of the IRC8M oscillator is shorter than the HXTAL crystal oscillator. An interrupt can be generated if the related interrupt enable bit, IRC8MSTBIE, in the interrupt register, RCU_INT, is set when the IRC8M becomes stable. The IRC8M clock can also be used as the system clock source or the PLL input clock.

The frequency accuracy of the IRC8M can be calibrated by the manufacturer, but its operating frequency is still less accurate than HXTAL. The application requirements, environment and cost will determine which oscillator type is selected.

If the HXTAL or PLL is the system clock source, to minimize the time required for the system to recover from the Deep-sleep Mode, the hardware forces the IRC8M clock to be the system clock when the system initially wakes-up.

Phase locked loop (PLL)

There are three internal Phase Locked Loop, the PLL, PLL1 and PLL2.

The internal Phase Locked Loop, PLL, can provide 16~120 MHz clock output which is 2 ~32 multiples of a fundamental reference frequency of 3 ~ 25 MHz.

The PLL has three input clock sources: IRC8M/2 or HXTAL or PLL1. It can be choosed one of them as the input clock source of the PLL.

The PLL can be switched on or off by using the PLLEN bit in the RCU_CTL register. The PLLSTB flag in the RCU_CTL register will indicate if the PLL clock is stable. An interrupt can be generated if the related interrupt enable bit, PLLSTBIE, in the RCU_INT register, is set as the PLL becomes stable

The PLL1 can be switched on or off by using the PLL1EN bit in the RCU_CTL register. The PLL1STB flag in the RCU_CTL Register will indicate if the PLL1 clock is stable. An interrupt can be generated if the related interrupt enable bit, PLL1STBIE, in the RCU_INT register, is set as the PLL1 becomes stable.

The PLL2 can be switched on or off by using the PLL2EN bit in the RCU_CTL register. The PLL2STB flag in the RCU_CTL register will indicate if the PLL2 clock is stable. An interrupt can be generated if the related interrupt enable bit, PLL2STBIE, in the RCU_INT register, is set as the PLL2 becomes stable.

The three PLLs are closed by hardware when entering the Deepsleep/Standby mode or HXTAL monitor fail when HXTAL used as the source clock of the PLLs.

The input clock source of PLL1 and PLL2 is obtained by HXTAL. It can be configured by PLL2MF[3:0], PLL1MF[3:0] and PREDV1[3:0] bits in the configuration register 1(RCU_CFG1).

Low speed crystal oscillator (LXTAL)

The low speed external crystal or ceramic resonator oscillator, which has a frequency of 32,768 Hz, produces a low power but highly accurate clock source for the Real Time Clock circuit. The LXTAL oscillator can be switched on or off by setting the LXTALEN bit in the backup domain control register RCU_BDCTL. The LXTALSTB flag in the backup domain control register RCU_BDCTL will indicate if the LXTAL clock is stable. An interrupt can be generated if the related interrupt enable bit, LXTALSTBIE, in the Interrupt register RCU_INT is set when the LXTAL becomes stable.

Select external clock bypass mode by setting the LXTALBPS and LXTALEN bits in the backup domain control register (RCU_BDCTL). The CK_LXTAL is equal to the external clock which drives the OSC32IN pin.

Internal 40 RC oscillator (IRC40K)

The internal RC oscillator has a frequency of about 40 kHz and is a low power clock source for the Real Time Clock circuit or the Free Watchdog Timer. The IRC40K offers a low cost clock source as no external components are required. The IRC40K RC oscillator can be switched on or off by setting the IRC40KEN bit in the Reset source/clock register, RCU_RSTSCK. The IRC40KSTB flag in the reset source/clock register RCU_RSTSCK will indicate if the IRC40K clock is stable. An interrupt can be generated if the related interrupt

enable bit IRC40KSTBIE in the interrupt register RCU_INT is set when the IRC40K becomes stable.

The IRC40K can be trimmed by TIMER4_CH3, user can get the clocks frequency, and adjust the RTC and FWDGT counter. Please refer to TIMER4CH3_IREMAP in AFIO_PCF0 register.

System clock (CK_SYS) selection

After the system reset, the default CK_SYS source will be IRC8M and can be switched to HXTAL or CK_PLL by changing the system clock switch bits, SCS, in the Clock configuration register 0(RCU_CFG0). When the SCS value is changed, the CK_SYS will continue to operate using the original clock source until the target clock source is stable. When a clock source is directly or indirectly (by PLL) used as the CK_SYS, it is not possible to stop it.

HXTAL clock monitor (CKM)

The HXTAL clock monitor function is enabled by the HXTAL clock monitor enable bit, CKMEN, in the control register (RCU_CTL). This function should be enabled after the HXTAL start-up delay is completed and disabled after the HXTAL is stopped. Once the HXTAL failure is detected, the HXTAL will be automatically disabled. The HXTAL clock stuck interrupt flag, CKMIF, in the Interrupt register, RCU_INT, will be set and the HXTAL failure event will be generated. This failure interrupt is connected to the Non-Maskable Interrupt, NMI, of the Cortex-M3. If the HXTAL is selected as the clock source of CK_SYS, PLL and CK_RTC, the HXTAL failure will force the CK_SYS source to IRC8M, the PLL will be disabled automatically. If the HXTAL is selected as the clock source of PLL, the HXTAL failure will force the PLL closed automatically.

Clock output capability

The clock output capability is ranging from 30 KHz to 60 MHz.

CK_OUT0

There are several clock signals can be selected via the CK_OUT0 clock source selection bits, CKOUT0SEL, in the clock configuration register 0 (RCU_CFG0). The corresponding GPIO pin should be configured in the properly Alternate Function I/O (AFIO) mode to output the selected clock signal.

Table 5-1. Clock Output 0 source select

CKOUT0SEL	Clock Source
00xx	No Clock
0100	CK_SYS
0101	CK_IRC8M
0110	CK_HXTAL
0111	CK_PLL/2
1000	CK_PLL1
1001	(CK_PLL2)/2
1010	EXT1

CKOUT0SEL	Clock Source
1011	CK_PLL2

The CKOUT0 frequency can be reduced by a configurable binary divider, controlled by the CKOUT0DIV[5:0] bits , in the configuration register 2, RCU_CFG2.

CK_OUT1

There are several clock signals can be selected via the CKOUT1 clock source selection bits, CKOUT1SEL, in the configuration register 2, RCU_CFG2. The corresponding GPIO pin should be configured in the properly Alternate Function I/O (AFIO) mode to output the selected clock signal.

Table 5-2. Clock Output 1 source select

CKOUT1SEL	Clock Source
00xx	No Clock
0100	CK_SYS
0101	CK_IRC8M
0110	CK_HXTAL
0111	CK_PLL/2
1000	CK_PLL1
1001	(CK_PLL2)/2
1010	EXT1
1011	CK_PLL2

The CKOUT1 frequency can be reduced by a configurable binary divider, controlled by the CKOUT1DIV[5:0] bits , in the configuration register 2, RCU_CFG2.

Voltage control

The 1.2V domain voltage in Deep-sleep mode can be controlled by DSLPVS[2:0] bit in the Deep-sleep mode voltage register (RCU_DSV).

Table 5-3. 1.2V domain voltage selected in deep-sleep mode

DSLPVS[2:0]	Deep-sleep mode voltage(V)
000	1.2
001	1.1
010	1.0
011	0.9

5.3. Register definition

RCU start address: 0x4002 1000

5.3.1. Control register (RCU_CTL)

Address offset: 0x00

Reset value: 0x0000 xx83 where x is undefined.

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31:30	Reserved	Must be kept at reset value.
29	PLL2STB	PLL2 Clock Stabilization Flag Set by hardware to indicate if the PLL2 output clock is stable and ready for use. 0: PLL2 is not stable 1: PLL2 is stable
28	PLL2EN	PLL2 enable Set and reset by software. Reset by hardware when entering Deep-sleep or Standby mode. 0: PLL2 is switched off 1: PLL2 is switched on
27	PLL1STB	PLL1 Clock Stabilization Flag Set by hardware to indicate if the PLL1 output clock is stable and ready for use. 0: PLL1 is not stable 1: PLL1 is stable
26	PLL1EN	PLL1 enable Set and reset by software. Reset by hardware when entering Deep-sleep or Standby mode. 0: PLL1 is switched off 1: PLL1 is switched on
25	PLLSTB	PLL Clock Stabilization Flag

		Set by hardware to indicate if the PLL output clock is stable and ready for use. 0: PLL is not stable 1: PLL is stable
24	PLLEN	PLL enable Set and reset by software. This bit cannot be reset if the PLL clock is used as the system clock. Reset by hardware when entering Deep-sleep or Standby mode. 0: PLL is switched off 1: PLL is switched on
23:20	Reserved	Must be kept at reset value.
19	CKMEN	HXTAL Clock Monitor Enable 0: Disable the High speed 3 ~ 25 MHz crystal oscillator (HXTAL) clock monitor 1: Enable the High speed 3 ~ 25 MHz crystal oscillator (HXTAL) clock monitor When the hardware detects that the HXTAL clock is stuck at a low or high state, the internal hardware will switch the system clock to be the internal high speed IRC8M RC clock. The way to recover the original system clock is by either an external reset, power on reset or clearing CKMIF by software. **Note:** When the HXTAL clock monitor is enabled, the hardware will automatically enable the IRC8M internal RC oscillator regardless of the control bit, IRC8MEN, state.
18	HXTALBPS	High speed crystal oscillator (HXTAL) clock bypass mode enable The HXTALBPS bit can be written only if the HXTALEN is 0. 0: Disable the HXTAL Bypass mode 1: Enable the HXTAL Bypass mode in which the HXTAL output clock is equal to the input clock.
17	HXTALSTB	High speed crystal oscillator (HXTAL) clock stabilization flag Set by hardware to indicate if the HXTAL oscillator is stable and ready for use. 0: HXTAL oscillator is not stable 1: HXTAL oscillator is stable
16	HXTALEN	High Speed crystal oscillator (HXTAL) Enable Set and reset by software. This bit cannot be reset if the HXTAL clock is used as the system clock or the PLL input clock when PLL clock is selected to the system clock. Reset by hardware when entering Deep-sleep or Standby mode. 0: High speed 3 ~ 25 MHz crystal oscillator disabled 1: High speed 3 ~ 25 MHz crystal oscillator enabled
15:8	IRC8MCALIB[7:0]	Internal 8MHz RC Oscillator calibration value register These bits are load automatically when power on.
7:3	IRC8MADJ[4:0]	Internal 8MHz RC Oscillator clock trim adjust value These bits are set by software. The trimming value is these bits (IRC8MADJ) added to the IRC8MCALIB[7:0] bits. The trimming value should trim the IRC8M to 8 MHz

± 1%.

2	Reserved	Must be kept at reset value.
1	IRC8MSTB	IRC8M Internal 8MHz RC Oscillator stabilization Flag Set by hardware to indicate if the IRC8M oscillator is stable and ready for use. 0: IRC8M oscillator is not stable 1: IRC8M oscillator is stable
0	IRC8MEN	Internal 8MHz RC oscillator Enable Set and reset by software. This bit cannot be reset if the IRC8M clock is used as the system clock. Set by hardware when leaving Deep-sleep or Standby mode or the HXTAL clock is stuck at a low or high state when CKMEN is set. 0: Internal 8 MHz RC oscillator disabled 1: Internal 8 MHz RC oscillator enabled

5.3.2. Configuration register 0 (RCU_CFG0)

20	PLLSTBIC	PLL stabilization Interrupt Clear Write 1 by software to reset the PLLSTBIF flag. 0: Not reset PLLSTBIF flag 1: Reset PLLSTBIF flag
19	HXTALSTBIC	HXTAL Stabilization Interrupt Clear Write 1 by software to reset the HXTALSTBIF flag. 0: Not reset HXTALSTBIF flag 1: Reset HXTALSTBIF flag
18	IRC8MSTBIC	IRC8M Stabilization Interrupt Clear Write 1 by software to reset the IRC8MSTBIF flag. 0: Not reset IRC8MSTBIF flag 1: Reset IRC8MSTBIF flag
17	LXTALSTBIC	LXTAL Stabilization Interrupt Clear Write 1 by software to reset the LXTALSTBIF flag. 0: Not reset LXTALSTBIF flag 1: Reset LXTALSTBIF flag
16	IRC40KSTBIC	IRC40K Stabilization Interrupt Clear Write 1 by software to reset the IRC40KSTBIF flag. 0: Not reset IRC40KSTBIF flag 1: Reset IRC40KSTBIF flag
15	Reserved	Must be kept at reset value
14	PLL2STBIE	PLL2 Stabilization Interrupt Enable Set and reset by software to enable/disable the PLL2 stabilization interrupt. 0: Disable the PLL2 stabilization interrupt

		1: Enable the PLL2 stabilization interrupt
13	PLL1STBIE	PLL1 Stabilization Interrupt Enable Set and reset by software to enable/disable the PLL1 stabilization interrupt. 0: Disable the PLL1 stabilization interrupt 1: Enable the PLL1 stabilization interrupt
12	PLLSTBIE	PLL Stabilization Interrupt Enable Set and reset by software to enable/disable the PLL stabilization interrupt. 0: Disable the PLL stabilization interrupt 1: Enable the PLL stabilization interrupt
11	HXTALSTBIE	HXTAL Stabilization Interrupt Enable Set and reset by software to enable/disable the HXTAL stabilization interrupt 0: Disable the HXTAL stabilization interrupt 1: Enable the HXTAL stabilization interrupt
10	IRC8MSTBIE	IRC8M Stabilization Interrupt Enable Set and reset by software to enable/disable the IRC8M stabilization interrupt 0: Disable the IRC8M stabilization interrupt 1: Enable the IRC8M stabilization interrupt
9	LXTALSTBIE	LXTAL Stabilization Interrupt Enable LXTAL stabilization interrupt enable/disable control 0: Disable the LXTAL stabilization interrupt 1: Enable the LXTAL stabilization interrupt
8	IRC40KSTBIE	IRC40K Stabilization interrupt enable IRC40K stabilization interrupt enable/disable control 0: Disable the IRC40K stabilization interrupt 1: Enable the IRC40K stabilization interrupt
7	CKMIF	HXTAL Clock Stuck Interrupt Flag Set by hardware when the HXTAL clock is stuck. Reset when setting the CKMIC bit by software. 0: Clock operating normally 1: HXTAL clock stuck
6	PLL2STBIF	PLL2 stabilization interrupt flag Set by hardware when the PLL2 is stable and the PLL2STBIE bit is set. Reset when setting the PLL2STBIC bit by software. 0: No PLL2 stabilization interrupt generated 1: PLL2 stabilization interrupt generated
5	PLL1STBIF	PLL1 stabilization interrupt flag Set by hardware when the PLL1 is stable and the PLL1STBIE bit is set. Reset when setting the PLL1STBIC bit by software. 0: No PLL1 stabilization interrupt generated

1: PLL1 stabilization interrupt generated

4	PLLSTBIF	PLL stabilization interrupt flag Set by hardware when the PLL is stable and the PLLSTBIE bit is set. Reset when setting the PLLSTBIC bit by software. 0: No PLL stabilization interrupt generated 1: PLL stabilization interrupt generated
3	HXTALSTBIF	HXTAL stabilization interrupt flag Set by hardware when the High speed 3 ~ 25 MHz crystal oscillator clock is stable and the HXTALSTBIE bit is set. Reset when setting the HXTALSTBIC bit by software. 0: No HXTAL stabilization interrupt generated 1: HXTAL stabilization interrupt generated
2	IRC8MSTBIF	IRC8M stabilization interrupt flag Set by hardware when the Internal 8 MHz RC oscillator clock is stable and the IRC8MSTBIE bit is set. Reset when setting the IRC8MSTBIC bit by software. 0: No IRC8M stabilization interrupt generated 1: IRC8M stabilization interrupt generated
1	LXTALSTBIF	LXTAL stabilization interrupt flag Set by hardware when the Low speed 32,768 Hz crystal oscillator clock is stable and the LXTALSTBIE bit is set. Reset when setting the LXTALSTBIC bit by software. 0: No LXTAL stabilization interrupt generated 1: LXTAL stabilization interrupt generated
0	IRC40KSTBIF	IRC40K stabilization interrupt flag Set by hardware when the Internal 40kHz RC oscillator clock is stable and the IRC40KSTBIE bit is set. Reset when setting the IRC40KSTBIC bit by software. 0: No IRC40K stabilization clock ready interrupt generated 1: IRC40K stabilization interrupt generated

5.3.4. APB2 reset register (RCU_APB2RST)

Address offset: 0x0C

Reset value: 0x00000 0000

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)

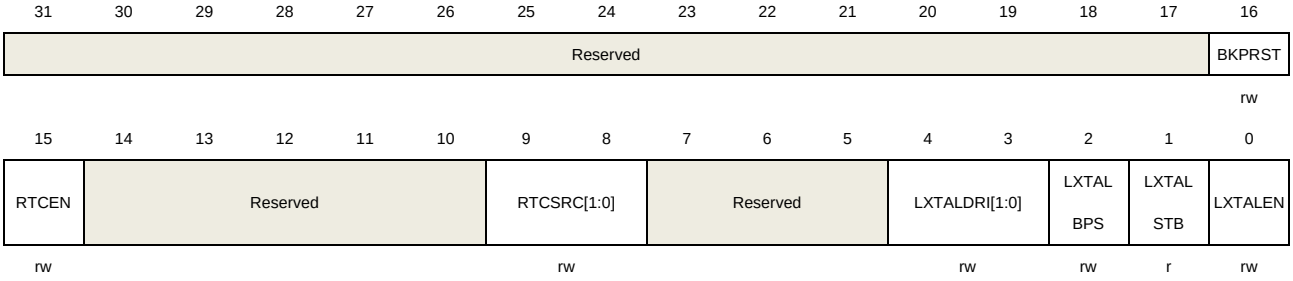
0	TIMER1EN	TIMER1 clock enable This bit is set and reset by software. 0: Disabled TIMER1 clock 1: Enabled TIMER1 clock

5.3.9. Backup domain control register (RCU_BDCTL)

Address offset: 0x20
Reset value: 0x0000 0018, reset by Backup domain Reset.

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)

Note: The LXTALEN, LXTALBPS, LXTALDRI, RTCSRC and RTCEN bits of the Backup domain control register (RCU_BDCTL) are only reset after a Backup domain Reset. These bits can be modified only when the BKPWEN bit in the Power control register (PMU_CTL) has to be set.



Bits	Fields	Descriptions
31:17	Reserved	Must be kept at reset value
16	BKPRST	Backup domain reset This bit is set and reset by software. 0: No reset 1: Resets Backup domain
15	RTCEN	RTC clock enable This bit is set and reset by software. 0: Disabled RTC clock 1: Enabled RTC clock
14:10	Reserved	Must be kept at reset value
9:8	RTCSRC[1:0]	RTC clock entry selection Set and reset by software to control the RTC clock source. Once the RTC clock source has been selected, it cannot be changed anymore unless the Backup domain is reset. 00: No clock selected

		01: CK_LXTAL selected as RTC source clock 10: CK_IRC40K selected as RTC source clock 11: (CK_HXTAL / 128) selected as RTC source clock
7:5	Reserved	Must be kept at reset value
4:3	LXTALDRI[1:0]	LXTAL drive capability Set and reset by software. Backup domain reset resets this value. 00: lower driving capability 01: medium low driving capability 10: medium high driving capability 11: higher driving capability (reset value) **Note:** The LXTALDRI is not in bypass mode.
2	LXTALBPS	LXTAL bypass mode enable Set and reset by software. 0: Disable the LXTAL Bypass mode 1: Enable the LXTAL Bypass mode
1	LXTALSTB	Low speed crystal oscillator stabilization flag Set by hardware to indicate if the LXTAL output clock is stable and ready for use. 0: LXTAL is not stable 1: LXTAL is stable
0	LXTALEN	LXTAL enable Set and reset by software. 0: Disable LXTAL 1: Enable LXTAL

5.3.10. Reset source/clock register (RCU_RSTSCK)

Address offset: 0x24

Reset value: 0x0C00 0000, ALL reset flags reset by power Reset only, RSTFC/IRC40KEN reset by system reset.

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31	LPRSTF	Low-power reset flag Set by hardware when Deep-sleep /standby reset generated. Reset by writing 1 to the RSTFC bit. 0: No Low-power management reset generated 1: Low-power management reset generated
30	WWDGTRSTF	Window watchdog timer reset flag Set by hardware when a window watchdog timer reset generated. Reset by writing 1 to the RSTFC bit. 0: No window watchdog reset generated 1: Window watchdog reset generated
29	FWDGTRSTF	Free watchdog timer reset flag Set by hardware when a free watchdog timer reset generated. Reset by writing 1 to the RSTFC bit. 0: No free watchdog timer reset generated 1: free Watchdog timer reset generated
28	SWRSTF	Software reset flag Set by hardware when a software reset generated. Reset by writing 1 to the RSTFC bit. 0: No software reset generated 1: Software reset generated
27	PORRSTF	Power reset flag Set by hardware when a Power reset generated. Reset by writing 1 to the RSTFC bit. 0: No Power reset generated 1: Power reset generated
26	EPRSTF	External PIN reset flag Set by hardware when an External PIN reset generated. Reset by writing 1 to the RSTFC bit. 0: No External PIN reset generated 1: External PIN reset generated
25	Reserved	Must be kept at reset value
24	RSTFC	Reset flag clear This bit is set by software to clear all reset flags. 0: Not clear reset flags 1: Clear reset flags
23:2	Reserved	Must be kept at reset value
1	IRC40KSTB	IRC40K stabilization flag Set by hardware to indicate if the IRC40K output clock is stable and ready for use.

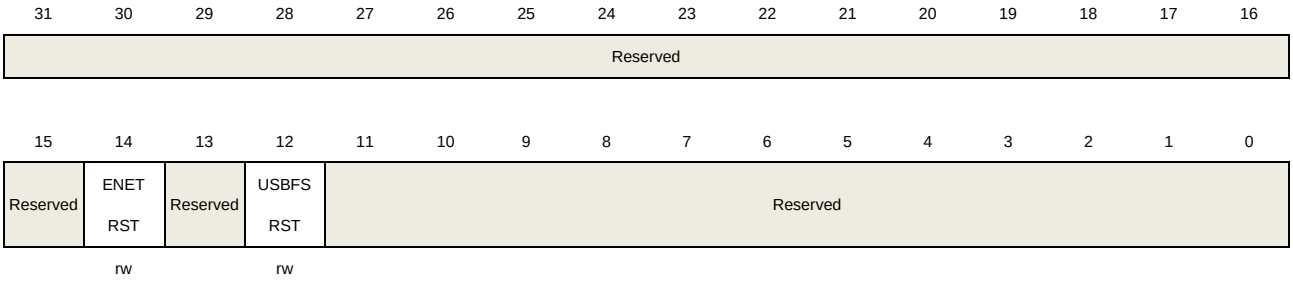
0: IRC40K is not stable
1: IRC40K is stable

0	IRC40KEN	IRC40K enable Set and reset by software. 0: Disable IRC40K 1: Enable IRC40K

5.3.11. AHB1 reset register (RCU_AHB1RST)

Address offset: 0x28
Reset value: 0x0000 0000

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)

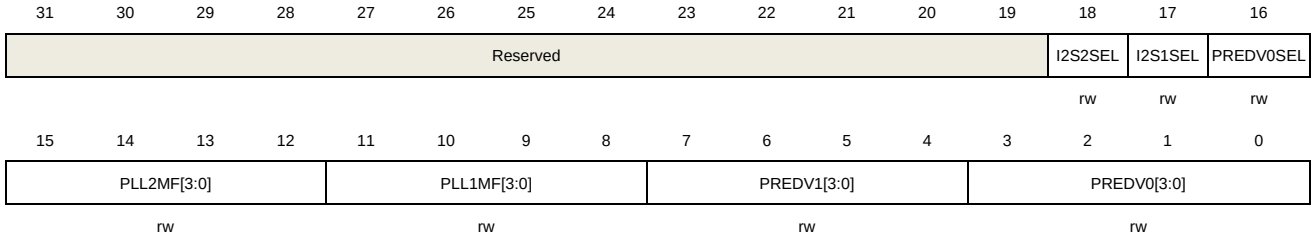


Bits	Fields	Descriptions
31:15	Reserved	Must be kept at reset value
14	ENETRST	ENET reset This bit is set and reset by software. 0: No reset 1: Reset the ENET
13	Reserved	Must be kept at reset value
12	USBFSRST	USBFS reset This bit is set and reset by software. 0: No reset 1: Reset the USBFS
11:0	Reserved	Must be kept at reset value

5.3.12. Configuration register 1 (RCU_CFG1)

Address offset: 0x2C
Reset value: 0x0000 0000

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)



Bits	Fields	Descriptions
31:19	Reserved	Must be kept at reset value
18	I2S2SEL	I2S2 clock source selection Set and reset by software to control the I2S2 clock source. 0: System clock selected as I2S2 source clock 1: (CK_PLL2 x 2) selected as I2S2 source clock
17	I2S1SEL	I2S1 clock source selection Set and reset by software to control the I2S1 clock source. 0: System clock selected as I2S1 source clock 1: (CK_PLL2 x 2) selected as I2S1 source clock
16	PREDV0SEL	PREDV0 input clock source selection Set and reset by software. 0: HXTAL selected as PREDV0 input source clock 1: CK_PLL1 selected as PREDV0 input source clock
15:12	PLL2MF[3:0]	PLL2 multiply factor These bits are written by software to define the PLL2 multiplication factor. 00xx: reserve 010x: reserve 0110: (PLL2 source clock x 8) 0111: (PLL2 source clock x 9) 1000 :(PLL2 source clock x 10) 1001: (PLL2 source clock x 11) 1010: (PLL2 source clock x 12) 1011: (PLL2 source clock x 13) 1100: (PLL2 source clock x 14) 1101: (PLL2 source clock x 15) 1110 :(PLL2 source clock x 16) 1111: (PLL2 source clock x 20)
11:8	PLL1MF[3:0]	The PLL1 clock multiplication factor Set and reset by software. 00xx: reserve 010x: reserve 0110: (PLL1 source clock x 8)

0111: (PLL1 source clock x 9)
1000 :(PLL1 source clock x 10)
1001: (PLL1 source clock x 11)
1010: (PLL1 source clock x 12)
1011: (PLL1 source clock x 13)
1100: (PLL1 source clock x 14)
1101: (PLL1 source clock x 15)
1110 :(PLL1 source clock x 16)
1111: (PLL1 source clock x 20)

7:4	PREDV1[3:0]	PREDV1 division factor This bit is set and reset by software. These bits can be written when PLL1 and PLL2 are disable. 0000: PREDV1 input source clock not divided 0001: PREDV1 input source clock divided by 2 0010: PREDV1 input source clock divided by 3 0011: PREDV1 input source clock divided by 4 0100: PREDV1 input source clock divided by 5 0101: PREDV1 input source clock divided by 6 0110: PREDV1 input source clock divided by 7 0111: PREDV1 input source clock divided by 8 1000: PREDV1 input source clock divided by 9 1001: PREDV1 input source clock divided by 10 1010: PREDV1 input source clock divided by 11 1011: PREDV1 input source clock divided by12 1100: PREDV1 input source clock divided by 13 1101: PREDV1 input source clock divided by 14 1110: PREDV1 input source clock divided by 15 1111: PREDV1 input source clock divided by 16
3:0	PREDV0	PREDV0 division factor This bit is set and reset by software. These bits can be written when PLL is disable. **Note:** The bit 0 of PREDV0 is same as bit 17 of RCU_CFG0, so modifying Bit 17 of RCU_CFG0 aslo modifies bit 0 of RCU_CFG1. 0000: PREDV0 input source clock not divided 0001: PREDV0 input source clock divided by 2 0010: PREDV0 input source clock divided by 3 0011: PREDV0 input source clock divided by 4 0100: PREDV0 input source clock divided by 5 0101: PREDV0 input source clock divided by 6 0110: PREDV0 input source clock divided by 7 0111: PREDV0 input source clock divided by 8 1000: PREDV0 input source clock divided by 9 1001: PREDV0 input source clock divided by 10

1010: PREDV0 input source clock divided by 11
1011: PREDV0 input source clock divided by12
1100: PREDV0 input source clock divided by 13
1101: PREDV0 input source clock divided by 14
1110: PREDV0 input source clock divided by 15
1111: PREDV0 input source clock divided by 16

5.3.13. Deep-sleep mode voltage register (RCU_DSV)

Address offset: 0x34
Reset value: 0x0000 0000.

This register can be accessed by byte(8-bit),half-word(16-bit) and word(32-bit)

Reserved	PLLTMF[8:0]									PLLTPSC[5:0]					
	rw									rw					

Bits	Fields	Descriptions
31	PLLTSEL	PLLT clock source select This bit can be written only when PLLT is disabled 0: select CK_IRC8M 1: select CK_HXTAL
30:28	PLLTRPSC[2:0]	PLLTR prescaler selection Set and reset by software to control the TLI clock frequency. These bits should be written when the PLLT is disabled. PLLTR clock frequency = VCO frequency / PLLTRPSC ,with 2 ≤ PLLTRPSC ≤ 7 000: PLLTRPSC = 0, wrong configuration 001: PLLTRPSC = 1, wrong configuration 010: PLLTRPSC = 2 ... 111: PLLTRPSC = 7
27:18	Reserved	Must be kept at reset value
17:16	TLIPSC[1:0]	TLI prescaler selection These bits are set and cleared by software to control the frequency of CK_TLI. They should be written only if PLLT is disabled. CK_TLI frequency = f(PLLTR) / TLIPSC with 2 ≤ TLIPSC≤ 16 00: TLIPSC = 2 01: TLIPSC = 4

		10: TLIPSC = 8 11: TLIPSC = 16
15	Reserved	Must be kept at reset value
14:6	PLLTMF[8:0]	PLLT multiply factor for VCO Set and reset by software to control the multiplication factor of the VCO. These bits should be written when the PLLT is disabled. Only half-word and word accesses are allowed to write these bits. VCO output frequency = VCO input frequency x PLLTMF with 49 ≤ PLLTMF≤ 432 000000000: PLLTMF = 0, wrong configuration 000000001: PLLTMF = 1, wrong configuration ..... 000110000: PLLTMF = 48, wrong configuration 000110001: PLLTMF = 49 ... 011000000: PLLTMF = 192 011000001: PLLTMF = 193 ... 110110000: PLLTMF = 432 110110000: PLLTMF = 433, wrong configuration ... 111111111: PLLTMF = 511, wrong configuration
5:0	PLLTPSC[5:0]	PLLT prescaler selection These bits can be written only when PLLT is disabeled **Note:** The software has to set these bits correctly to ensure that the VCO input frequency ranges from 1 to 2 MHz. It is recommended to select a frequency of 2 MHz to limit PLL jitter. VCO input frequency = PLLT input clock frequency / PLLTPSC with 2 ≤PLLTPSC≤ 63 000000: PLLTPSC = 0, wrong configuration 000001: PLLTPSC = 1, wrong configuration 000010: PLLTPSC = 2 000011: PLLTPSC = 3 000100: PLLTPSC = 4 ... 111110: PLLTPSC = 62 111111: PLLTPSC = 63

6. Interrupt/event controller(EXTI)

6.1. Overview

Cortex-M3 integrates the Nested Vectored Interrupt Controller (NVIC) for efficient exception and interrupts processing. NVIC facilitates low-latency exception and interrupt handling and controls power management. It's tightly coupled to the processer core. You can read the Technical Reference Manual of Cortex-M3 for more details about NVIC.

EXTI (interrupt/event controller) contains up to 20 independent edge detectors and generates interrupt requests or events to the processer. The EXTI has three trigger types: rising edge, falling edge and both edges. Each edge detector in the EXTI can be configured and masked independently.

6.2. Characteristics

- Cortex-M3 system exception.
- Up to 90 maskable peripheral interrupts.
- 4 bits interrupt priority configuration—16 priority levels.
- Efficient interrupt processing.
- Support exception pre-emption and tail-chaining.
- Wake up system from power saving mode.
- Up to 20 independent edge detectors in EXTI.
- Three trigger types: rising, falling and both edges.
- Software interrupt or event trigger.
- Trigger sources configurable.

6.3. Interrupts function overview

The ARM Cortex-M3 processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR).

The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration. The following tables list all exception

types.

Table 6-1. NVIC exception types in Cortex-M3

Exception Type	Vector Number	Priority (a)	Vector Address	Description
-	0	-	0x0000_0000	Reserved
Reset	1	-3	0x0000_0004	Reset
NMI	2	-2	0x0000_0008	Non maskable interrupt.
HardFault	3	-1	0x0000_000C	All class of fault
MemManage	4	Programmable	0x0000_0010	Memory management
BusFault	5	Programmable	0x0000_0014	Prefetch fault, memory access fault
UsageFault	6	Programmable	0x0000_0018	Undefined instruction or illegal state
-	7-10	-	0x0000_001C - 0x0000_002B	Reserved
SVCall	11	Programmable	0x0000_002C	System service call via SWI instruction
Debug Monitor	12	Programmable	0x0000_0030	Debug Monitor
-	13	-	0x0000_0034	Reserved
PendSV	14	Programmable	0x0000_0038	Pendable request for system service
SysTick	15	Programmable	0x0000_003C	System tick timer

The SysTick calibration value is 15000 and SysTick clock frequency is fixed to HCLK*0.125. So this will give a 1ms SysTick interrupt if HCLK is configured to 120MHz.

Table 6-2. Interrupt vector table

Interrupt Number	Vector Number	Peripheral Interrupt Description	Vector Address
IRQ 0	16	WWDGT interrupt	0x0000_0040
IRQ 1	17	LVD from EXTI interrupt	0x0000_0044

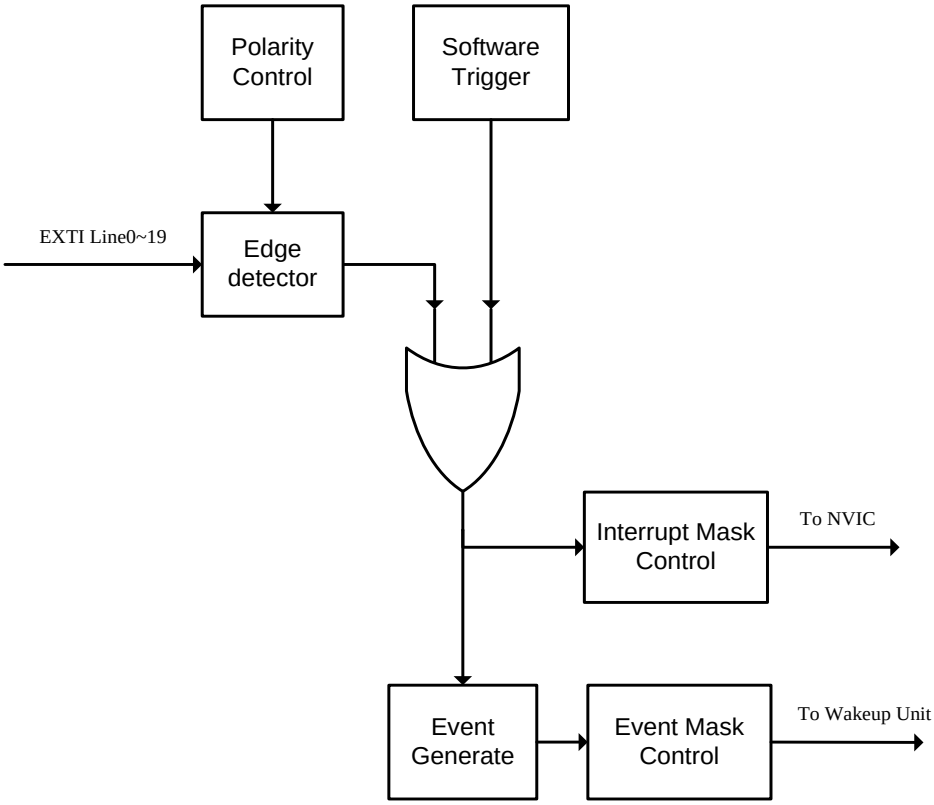
6.4. External interrupt and event (EXTI) block diagram

Figure 6-1. Block diagram of EXTI



6.5. External Interrupt and Event function overview

The EXTI contains up to 20 independent edge detectors and generates interrupts request or event to the processer. The EXTI has three trigger types: rising edge, falling edge and both edges. Each edge detector in the EXTI can be configured and masked independently.

The EXTI trigger source includes 16 external lines from GPIO pins and 4 lines from internal modules (including LVD, RTC Alarm, USBFS Wakeup, Ethernet Wakeup). All GPIO pins can be selected as an EXTI trigger source by configuring AFIO_EXTISSx registers in GPIO module (please refer to GPIO and AFIO section for detail).

EXTI can provide not only interrupts but also event signals to the processor. The Cortex-M3 processor fully implements the Wait For Interrupt (WFI), Wait For Event (WFE) and the Send Event (SEV) instructions. The Wake-up Interrupt Controller (WIC) enables the processor and NVIC to be put into a very low-power sleep mode leaving the WIC to identify and prioritize interrupts and event. EXTI can be used to wake up processor and the whole system when some expected event occurs, such as a special GPIO pin toggling or RTC alarm.

Table 6-3. EXTI source

EXTI Line Number	Source	Attribute
0	PA0/PB0/PC0/PD0/PE0/PF0/PG0/PH0/PI0	External
1	PA1/PB1/PC1/PD1/PE1/PF1/PG1/PH1/PI1	External

PD15	PD14	PD13	PD12	PD11	PD10	PD9	PD8	PD7	PD6	PD5	PD4	PD3	PD2	PD1	PD0
rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits	Fields	Descriptions
31: 20	Reserved	Must be kept at reset value
19: 0	PDx	Interrupt pending status 0: EXTI Linex is not triggered 1: EXTI Linex is triggered. This bit is cleared to 0 by writing 1 to it.

7. General-purpose and alternate-function I/Os (GPIO and AFIO)

7.1. Overview

There are up to 140 general purpose I/O pins (GPIO), named PA0 ~ PA15, PB0 ~ PB15, PC0 ~ PC15, PD0 ~ PD15, PE0 ~ PE15, PF0 ~ PF15, PG0 ~ PG15, PH0 ~ PH15 and PI0 ~ PI11 for the device to implement logic input/output functions. Each GPIO port has related control and configuration registers to satisfy the requirements of specific applications. The external interrupt on the GPIO pins of the device have related control and configuration registers in the Interrupt/event Controller Unit (EXIT).

The GPIO ports are pin-shared with other alternative functions (AFs) to obtain maximum flexibility on the package pins. The GPIO pins can be used as alternative functional pins by configuring the corresponding registers regardless of the AF input or output pins.

Each of the GPIO pins can be configured by software as output (push-pull or open-drain), input, peripheral alternate function or analog mode. Each GPIO pin can be configured as pull-up, pull-down or no pull-up/pull-down. All GPIOs are high-current capable except for analog mode.

7.2. Characteristics

- Input/output direction control.
- Schmitt trigger input function enable control.
- Each pin weak pull-up/pull-down function.
- Output push-pull/open drain enable control.
- Output set/reset control.
- External interrupt with programmable trigger edge – using EXTI configuration registers.
- Analog input/output configuration.
- Alternate function input/output configuration.
- Port configuration lock.

7.3. Function overview

Each of the general-purpose I/O ports can be configured as 8 modes: analog inputs, input floating, input pull-down/pull-up, GPIO push-pull/open-drain or AFIO push-pull/open-drain

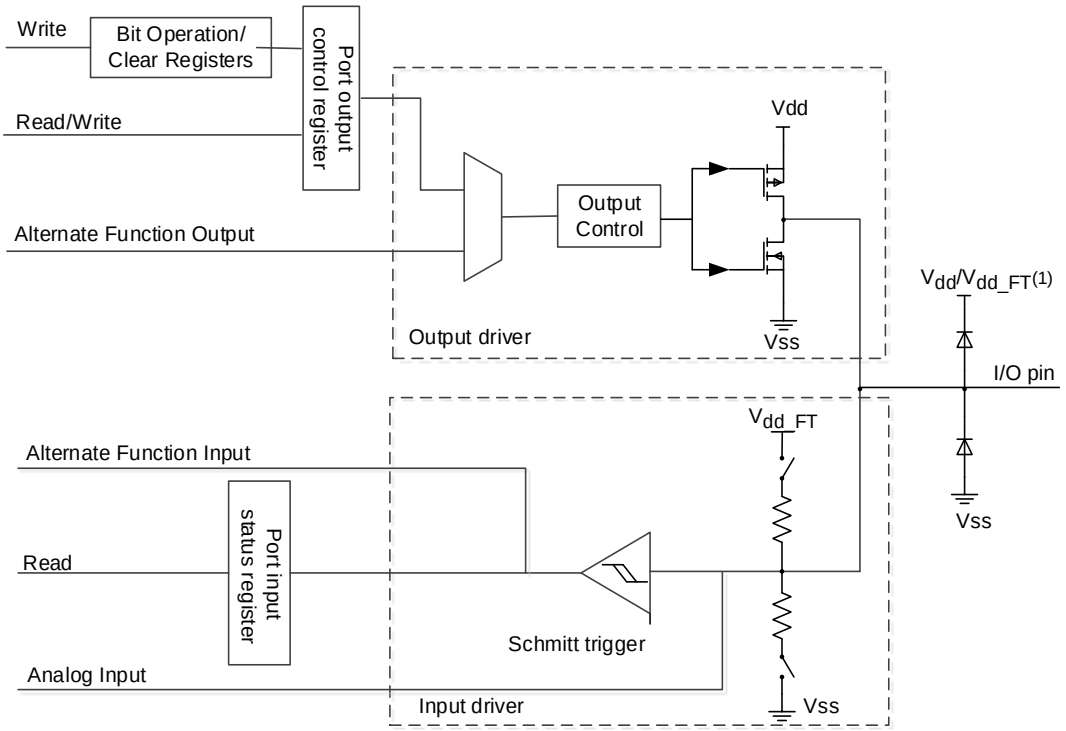
mode by two GPIO configuration registers (GPIOx_CTL0/GPIOx_CTL1), and two 32-bits data registers (GPIOx_ISTAT and GPIOx_OCTL).*Table 7-1. GPIO configuration table* shows the details.

Table 7-1. GPIO configuration table

Configuration mode		CTL[1:0]	MD[1:0]	OCTL
Input	Analog	00	00	don't care
	Input floating	01		don't care
	Input pull-down	10		0
	Input pull-up	10		1
General purpose Output (GPIO)	Push-pull	00	00: Not used 01: Speed up to 10MHz 10: Speed up to 2MHz 11: Speed up to 50MHz	0 or 1
	Open-drain	01		0 or 1
Alternate Function Output (AFIO)	Push-pull	10		don't care
	Open-drain	11		don't care

Figure 7-1. The basic structure of a standard I/O and five-volt tolerant I/O Port shows the basic structure of an I/O port bit.

Figure 7-1. The basic structure of a standard I/O and five-volt tolerant I/O Port



1. V_{dd_FT} dedicated for five-volt tolerant I/Os and is different from V_{dd}

7.3.1. GPIO pin configuration

During or just after the reset period, the alternative functions are all inactive, and the GPIO ports are configured in input floating mode, which disables Pull-Up (PU)/Pull-Down (PD) resistors. But the JTAG/Serial-Wired Debug pins are in input PU/PD mode after reset:

PA15: JTDI in PU mode.

PA14: JTCK / SWCLK in PD mode.

PA13: JTMS / SWDIO in PU mode.

PB4: NJTRST in PU mode.

The GPIO pins can be configured as inputs or outputs. When the GPIO pins are configured as input pins, all GPIO pins have an internal weak pull-up and weak pull-down which can be chosen. And the data on the external pins can be captured at every APB2 clock cycle to the port input status register (GPIOx_ISTAT).

When the GPIO pins are configured as output pins, user can configure the speed of the ports. And chooses the output driver mode: Push-Pull or Open-Drain mode. The value of the port output control register (GPIOx_OCTL) is output on the I/O pin.

There is no need to read-then-write when programming the GPIOx_OCTL at bit level, user can modify only one or several bits in a single atomic APB2 write access by programming ‘1’ to the bit operate register (GPIOx_BOP, or for clearing only GPIOx_BC). The other bits will not be affected.

7.3.2. External interrupt/event lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode.

7.3.3. Alternate functions (AF)

When the port is configured as AFIO (set CTLy bits to “0b10” or “0b11”, and set MDy bits to “0b01”, “0b10”, or “0b11”, which is in GPIOx_CTL0/GPIOx_CTL1 registers), the port is used as peripheral alternate functions. The detail alternate function assignments for each port are in the device datasheet.

7.3.4. Input configuration

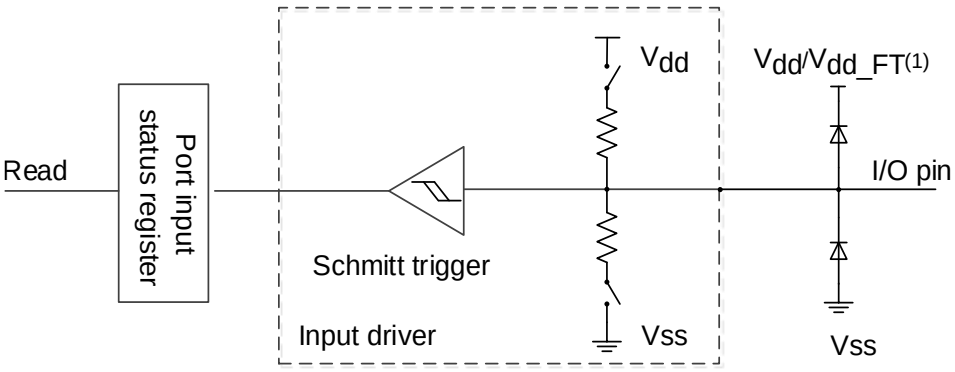
When GPIO pin is configured as Input:

- The schmitt trigger input is enabled.
- The weak pull-up and pull-down resistors could be chosen.
- Every APB2 clock cycle the data present on the I/O pin is got to the port input status Register.

- The output buffer is disabled.

Figure 7-2. Input configuration shows the input configuration.

Figure 7-2. Input configuration



1. V_{dd_FT} dedicated for five-volt tolerant I/Os and is different from V_{dd}

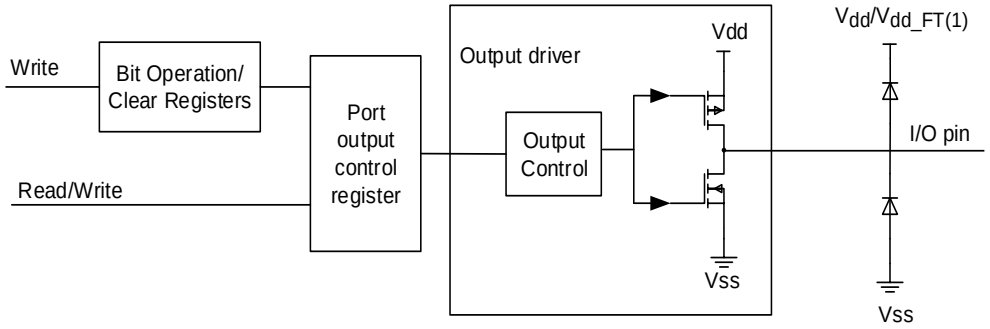
7.3.5. Output configuration

When GPIO pin is configured as output:

- The schmitt trigger input is enabled.
- The weak pull-up and pull-down resistors are disabled.
- The output buffer is enabled.
- Open Drain Mode: The pad output low level when a “0” in the output control register.
- while the pad leaves Hi-Z when a “1” in the output control register.
- Push-Pull Mode: The pad output low level when a “0” in the output control register;
- while the pad output high level when a “1” in the output control register.
- A read access to the port output control register gets the last written value.
- A read access to the port input status register gets the I/O state.

Figure 7-3. Output configuration shows the output configuration.

Figure 7-3. Output configuration



1. V_{dd_FT} dedicated for five-volt tolerant I/Os and is different from V_{dd}

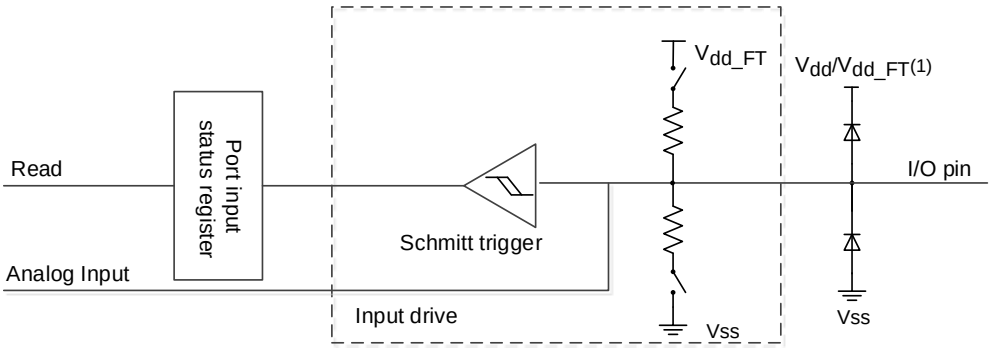
7.3.6. Analog configuration

When GPIO pin is used as analog configuration:

- The weak pull-up and pull-down resistors are disabled.
- The output buffer is disabled.
- The schmitt trigger input is disabled.
- The port input status register of this I/O port bit is “0”.

Figure 7-4. Analog configuration shows the analog configuration.

Figure 7-4. Analog configuration



1. V_{dd_FT} dedicated for five-volt tolerant I/Os and is different from V_{dd}

7.3.7. Alternate function (AF) configuration

To suit for different device packages, the GPIO supports some alternate functions mapped to some other pins by software.

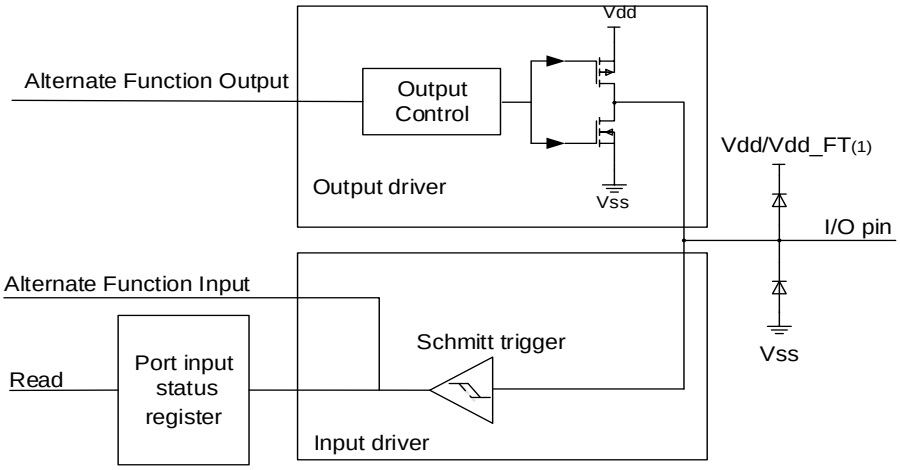
When be configured as alternate function:

- The output buffer is enabled in Open-Drain or Push-Pull configuration.

- The output buffer is driven by the peripheral.
- The schmitt trigger input is enabled.
- The weak pull-up and pull-down resistors are disable.
- The I/O pin data is stored into the port input status register every APB2 clock.
- A read access to the port input status register gets the I/O state.
- A read access to the port output control register gets the last written value.

Figure 7-5. Alternate function configuration shows the alternate function configuration.

Figure 7-5. Alternate function configuration



1. V_{dd_FT} dedicated for five-volt tolerant I/Os and is different from V_{dd}

7.3.8. IO pin function selection

Each IO pin can implement many functions, each function selected by GPIO registers.

GPIO:

Each IO pin can be used for GPIO input function by configuring MDy bits to 0b00 in GPIOx_CTL0/GPIOx_CTL1 registers. And set output function by configuring MDy bits to 0b01, 0b10, or 0b11 and configuring CTLy bits of corresponding port in GPIOx_CTL0/GPIOx_CTL1 register to 0b00 (for GPIO push-pull output) or 0b01 (for GPIO open-drain output).

Alternate function:

Each IO pin can be used for AF input function by configuring MDy bits to 0b00 in GPIOx_CTL0/GPIOx_CTL1 registers. And set output function by configuring MDy bits to 0b01, 0b10, or 0b11 and configuring CTLy bits of corresponding port in GPIOx_CTL0/GPIOx_CTL1 register to 0b10 (for AF push-pull output) or 0b11 (for AF open-drain output).

7.3.9. GPIO locking function

The locking mechanism allows the IO configuration to be protected.

The protected registers are GPIOx_CTL0, GPIOx_CTL1. It allows the I/O configuration to be frozen by the 32-bit locking register (GPIOx_LOCK). When the special LOCK sequence has been occurred on LKK bit in GPIOx_LOCK register and the LKy bit is set in GPIOx_LOCK register, the corresponding port is locked and the corresponding port configuration cannot be modified until the next reset. It should be recommended to be used in the configuration of driving a power module.

7.4. Remapping function I/O and debug configuration

7.4.1. Introduction

In order to expand the flexibility of the GPIO or the usage of peripheral functions, each I/O pin can be configured to have up to four different functions by setting the AFIO Port Configuration Register (AFIO_PCF0/AFIO_PCF1). Suitable pinout locations can be selected by using the peripheral IO remapping function. Additionally, various GPIO pins can be selected to be the EXTI interrupt line by setting the relevant EXTI Source Selection Register (AFIO_EXTISSx) to trigger an interrupt or event.

7.4.2. Main features

- APB slave interface for register access.
- EXTI source selection.
- Each pin has up to four alternative functions for configuration.

7.4.3. JTAG/SWD alternate function remapping

The debug interface signals are mapped on the GPIO ports as shown in table below.

Table 7-2. Debug interface signals

Alternate function	GPIO port
JTMS / SWDIO	PA13
JTCK / SWCLK	PA14
JTDI	PA15
JTDO / TRACESWO	PB3
NJTRST	PB4
TRACECK	PE2
TRACECK0	PE3
TRACECK1	PE4

Alternate function	GPIO port
TRACECK2	PE5
TRACECK3	PE6

To reduce the number of GPIOs used to debug, user can configure SWJ_CFG [2:0] bits in the AFIO_PCF0 to different value. Refer to table below.

Table 7-3. Debug port mapping

SWJ _CFG [2:0]	Available debug ports	SWJ I/O pin assigned				
		PA13/ JTMS/ SWDIO	PA14/ JTCK/SWCLK	PA15/ JTDI	PB3/ JTDO/ TRACESWO	PB4/ NJTRST
000	Full SWJ (JTAG-DP + SW-DP) (Reset state)	●	●	●	●	●
001	Full SWJ (JTAG-DP + SW-DP) but without NJTRST	●	●	●	●	X
010	JTAG-DP Disabled and SW-DP Enabled	●	●	X	X (1)	X
100	JTAG-DP Disabled and SW-DP Disabled	X	X	X	X	X
Other	Forbidden					

1.Released only if not using asynchronous trace.

7.4.4. ADC AF remapping

Refer to AFIO Port Configuration Register 0 (AFIO_ PCF0).

Table 7-4. ADC0 external trigger inserted conversion AF remapping

Alternate function	ADC0_ETRGINS_REMAP = 0	ADC0_ETRGINS_REMAP = 1
ADC0 external trigger inserted conversion	ADC0 external trigger inserted conversion is connected to EXTI15	ADC0 external trigger inserted conversion is connected to TIMER7_CH3

Table 7-5. ADC0 external trigger regular conversion AF remapping

Table 7-14. TIMER8 alternate function remapping (1)

Alternate function	TIMER8_REMAP = 0	TIMER8_REMAP = 1
TIMER8_CH0	PA2	PE5
TIMER8_CH1	PA3	PE6

1. Refer to the AF remap and debug I/O configuration register 1(AFIO_ PCF1)

Table 7-15. TIMER9 alternate function remapping (1)

Alternate function	TIMER9_REMAP = 0	TIMER9_REMAP = 1

TIMER9_CH0	PB8	PF6

1. Refer to the AF remap and debug I/O configuration register 1 (AFIO_ PCF1)

Table 7-16. TIMER10 alternate function remapping (1)

Alternate function	TIMER10_REMAP = 0	TIMER10_REMAP = 1
TIMER10_CH0	PB9	PF7

1. Refer to the AF remap and debug I/O configuration register 1(AFIO_ PCF1)

Table 7-17. TIMER11 alternate function remapping (1)

Alternate function	TIMER11_REMAP = 0	TIMER11_REMAP = 1
TIMER11_CH0	PB14	PH6
TIMER11_CH1	PB15	PH9

1. Refer to the AF remap and debug I/O configuration register 1(AFIO_ PCF5)

Table 7-18. TIMER12 alternate function remapping (1)

Alternate function	TIMER12_REMAP = 0	TIMER12_REMAP = 1
TIMER12_CH0	PA6	PF8

1. Refer to the AF remap and debug I/O configuration register 1(AFIO_ PCF1)

Table 7-19. TIMER13 alternate function remapping (1)

Alternate function	TIMER13_REMAP = 0	TIMER13_REMAP = 1
TIMER13_CH0	PA7	PF9

1. Refer to the AF remap and debug I/O configuration register 1(AFIO_PCF1)

7.4.6. USART AF remapping

Refer to AFIO port configuration register 0 (AFIO_PCF0).

Table 7-20. USART0 alternate function remapping

Alternate function	USART0_REMAP = 0	USART0_REMAP = 1
USART0_TX	PA9	PB6
USART0_RX	PA10	PB7

Table 7-21. USART1 alternate function remapping

Alternate function	USART1_REMAP = 0	USART1_REMAP = 1 (1)
USART1_CTS	PA0	PD3
USART1_RTS	PA1	PD4
USART1_TX	PA2	PD5
USART1_RX	PA3	PD6
USART1_CK	PA4	PD7

1. Remap available only for 100-pin, 144-pin and 176-pin packages

Table 7-22. USART2 alternate function remapping

Alternate function	USART2_REMAP [1:0] = “00” (no remap)	USART2_REMAP [1:0] =“01” (partial remap)	USART2_REMAP [1:0] =“11” (full remap) (1)
USART2_TX	PB10	PC10	PD8
USART2_RX	PB11	PC11	PD9
USART2_CK	PB12	PC12	PD10
USART2_CTS	PB13		PD11
USART2_RTS	PB14		PD12

1. Remap available only for 100-pin, 144-pin and 176-pin packages

Table 7-23. UART3 alternate function remapping

Alternate function	UART3_REMAP = 0	UART3_REMAP = 1
UART3_TX	PC10	PA0
UART3_RX	PC11	PA1

Table 7-24. USART5 alternate function remapping

Alternate function	USART5_XX_REMAP = 0	USART5_XX_REMAP = 1
USART5_TX	PC6	PG14
USART5_RX	PC7	PG9
USART5_CK	PC8	PG7
USART5_CTS	PG15	PG13
USART5_RTS	PG8	PG12

Table 7-25. UART6 alternate function remapping

Alternate function	UART6_REMAP = 0	UART6_REMAP = 1
UART6_TX	PE8	PF7
UART6_RX	PE7	PF6

7.4.7. I2C AF remapping

Refer to AFIO port configuration register 0 (AFIO_ PCF0).

Table 7-26. I2C0 alternate function remapping

Alternate function	I2C0_REMAP = 0	I2C0_REMAP = 1
I2C0_SCL	PB6	PB8
I2C0_SDA	PB7	PB9

Table 7-27. I2C1 alternate function remapping

Alternate function	I2C1_REMAP[1:0] = 00/01	I2C1_REMAP[1:0] = 10	I2C1_REMAP[1:0] = 11

I2C1_SCL	PB10	PH4	PF0
I2C1_SDA	PB11	PH5	PF1
I2C1_SMBA	PB12	PH6	PF2

Table 7-28. I2C2 alternate function remapping

Alternate function	I2C2_REMAP1 = 1	I2C2_REMAP2 = 1
I2C2_SCL	PA8	PH7
I2C2_SDA	PC9	PH8
I2C2_SMBA	PA9	PH9

7.4.8. SPI AF remapping

Table 7-29. SPI0 alternate function remapping (1)

Alternate function	SPI0_REMAP = 0	SPI0_REMAP = 1
SPI0_NSS	PA4	PA15
SPI0_SCK	PA5	PB3
SPI0_MISO	PA6	PB4
SPI0_MOSI	PA7	PB5
SPI0_IO2	PA2	PB6
SPI0_IO3	PA3	PB7

1. Refer to AFIO port configuration register 0 (AFIO_ PCF0).

Table 7-30. SPI1/I2S1 alternate function remapping

Alternate function	SPI1_NSCK /IO _REMAP = 00/01	SPI1_NSCK /IO _REMAP = 10	SPI1_NSCK /IO _REMAP = 11	SPI1_SCK _REMAP = 1
SPI1_NSS/ I2S1_WS	PB12	PI0	PB9	
SPI1_SCK/ I2S1_CK	PB13	PI1	PB10	PD3
SPI1_MISO	PB14	PI2	PC2	
SPI1_MOSI/I2S2_SD	PB15	PI3	PC3	
I2S1_MCK	PC6			

Table 7-31. SPI2/I2S2 alternate function remapping (1)

Alternate function	SPI2_REMAP = 0	SPI2_REMAP = 1	SPI2_MOSI_REMAP = 1
SPI2_NSS/ I2S2_WS	PA15	PA4	
SPI2_SCK/ I2S2_CK	PB3	PC10	
SPI2_MISO	PB4	PC11	
SPI2_MOSI/I2S2_SD	PB5	PC12	PD6(SPI2)
I2S2_MCK	PC7		

1. Refer to AFIO port configuration register 0 (AFIO_ PCF0).

7.4.9. CAN AF remapping

The CAN0 signals can be mapped on Port A, Port B or Port D as shown in table below. For port D, remapping is not possible in devices delivered in 64-pin packages.

Table 7-32. CAN0 alternate function remapping

Alternate function	CAN0_REMAP [1:0] = "00"	CAN0_REMAP [1:0] = "10"	CAN0_REMAP [1:0] = "11" (1)	CAN0_ADD _REMAP = "1"
CAN0_RX	PA11	PB8	PD0	PI9
CAN0_TX	PA12	PB9	PD1	PH13

1. This remapping is available only on 100-pin packages, when PD0 and PD1 are not remapped on OSC_IN and OSC_OUT.

CAN1 external signals can be remapped as show table below.

Table 7-33. CAN1 alternate function remapping

Alternate function	CAN1_REMAP = "0"	CAN1_REMAP = "1"
CAN1_RX	PB12	PB5
CAN1_TX	PB13	PB6

7.4.10. Ethernet AF remapping

Table 7-34. ENET alternate function remapping

Alternate function	ENET_REMAP = 0	ENET_REMAP = 1	ENET_RX_HI_REMAP/ ENET_CRSCOL_REMAP/ ENET_TXD01_REMAP	ENET_RX_HI_REMAP/ ENET_CRSCOL_REMAP/ ENET_TXD01_REMAP
ETH_MII_CRS			PA0	PH2
ETH_MII_COL			PA3	PH3
ETH_MII_RX_DV/ ETH_RMII_CRS_DV	PA7	PD8		
ETH_MII_RXD0/ ETH_RMII_RXD0	PC4	PD9		
ETH_MII_RXD1/ ETH_RMII_RXD1	PC5	PD10		
ETH_MII_RXD2	PB0	PD11	refer to ENET_REMAP	PH6
ETH_MII_RXD3	PB1	PD12	refer to ENET_REMAP	PH7
ETH_MII_TXD3			PB8	PE2
ETH_MII_RX_ER			PB10	PI10
ETH_MII_TX_EN/ ETH_RMII_TX_EN			PB11	PG11
ETH_MII_TXD0/ ETH_RMII_TXD0			PB12	PG13
ETH_MII_TXD1/ ETH_RMII_TXD1			PB13	PG14

Alternate function	ENET_REMAP = 0	ENET_REMAP = 1	ENET_RX_HI_REMAP/ ENET_CRSCOL_REMAP/ ENET_TXD01_REMAP	ENET_RX_HI_REMAP/ ENET_CRSCOL_REMAP/ ENET_TXD01_REMAP
Alternate function			**PTP_PPS_REMAP = 1**	**PPS_HI_REMAP = 1**
ETH_PPS_OUT			PB5	PG8

7.4.11. DCI AF remapping

Table 7-35. DCI alternate function remapping

Alternate function	DCI_Dx_ REMAP = “00”	DCI_Dx_ REMAP = “01”	DCI_Dx_ REMAP = “10”	DCI_Dx_ REMAP = “11”
DCI_D0	PA9	PC6		PH9
DCI_D1	PA10	PC7		PH10
Alternate function	**DCI_Dx_ REMAP = “00”**	**DCI_Dx_ REMAP = “01”**	**DCI_Dx_ REMAP = “10”**	**DCI_Dx_ REMAP = “11”**
DCI_D2	PC8	PE0	PG10	PH11
DCI_D3	PC9	PE1	PG11	PH12
DCI_D4	PC11	PE4		PH14
DCI_D5	PB6	PD3		PI4
DCI_D6	PB8	PE5		PI6
DCI_D7	PB9	PE6		PI7
DCI_D8	PC10	PH6		PI1
DCI_D9	PC12	PH7		PI2
DCI_D10	PB5	PD6		PI3
DCI_D11	PD2	PF10		PH15
DCI_D12	PF11	PG6		
DCI_D13	PG7	PG15		PI0
DCI_HSYNC	PA4	PH8		
DCI_VSYNC	PB7	PG9		PI5

7.4.12. TLI AF remapping

Table 7-36. TLI alternate function remapping

Alternate function	AFIO_PCF3	AFIO_PCF4
	TLI_xx_Pn_ REMAP = 1(1)	**TLI_xx_Pn_ REMAP = 1(2)**
TLI_R0		PH2 / PH4
TLI_R1		PH3 / PI3
TLI_R2	PC10	PH8

TLI_R3	PB0	PH9
TLI_R4	PA11	PH10
TLI_R5	PA12	PH11
TLI_R6	PA8 / PB1	PH12
TLI_R7	PE15 / PG6	
TLI_G0	PE5	
TLI_G1	PE6	
TLI_G2	PA6	PH13
TLI_G3	PG10 / PE11	PH14
TLI_G4	PB10	PH15
TLI_G5	PB11	PI0
TLI_G6	PC7	PI1
TLI_G7	PD3	PI2
TLI_B0	PE4	
Alternate function	**AFIO_PCF3**	**AFIO_PCF4**
	TLI_xx_Pn_ REMAP = 1(1)	**TLI_xx_Pn_ REMAP = 1(2)**
TLI_B1		PG12
TLI_B2	PD6 / PG10	
TLI_B3	PD10 / PG11	
TLI_B4	PE12	PI4 / PG12
TLI_B5	PA3	PI5
TLI_B6	PB8	PI6
TLI_B7	PB9	PI7
TLI_DE	PE13 / PF10	
TLI_CLK	PE14 / PG7	
TLI_VSYNC	PA4	PI9
TLI_HSYNC	PC6	PI10

1. Refer to AFIO port configuration register 3 (AFIO_ PCF3)。
2. Refer to AFIO port configuration register 4 (AFIO_ PCF4)。

7.4.13. CLK pins AF remapping

The LXTAL oscillator pins OSC32_IN and OSC32_OUT can be used as general-purpose I/O PC14 and PC15 individually, when the LXTAL oscillator is off. The LXTAL has priority over the GPIOs function.

Note: 1. But when the 1.8 V domain is powered off (by entering standby mode) or when the backup domain is supplied by VBAT (VDD no more supplied), the PC14/PC15 GPIO functionality is lost and will be set in analog mode.

2. Refer to the note on IO usage restrictions in ***Battery backup domain***.

Table 7-37. OSC32 pins configuration

Alternate function	LXTAL= ON	LXTAL= OFF
PC14	OSC32_IN	PC14
PC15	OSC32_OUT	PC15

The HXTAL oscillator pins OSC_IN/OSC_OUT can be used as general-purpose I/O PD0/PD1.

Table 7-38. OSC pins configuration 1

Alternate function	PD01_REMAP = 0	PD01_REMAP = 1
PD0	PD0	OSC_IN
PD1	PD1	OSC_OUT

Table 7-39. OSC pins configuration 2

Alternate function	PH01_REMAP = 0	PH01_REMAP = 1(1)
PH0		OSC_IN
PH1		OSC_OUT

1. Only for 176 pin packages, PH0/PH1 default to OSC_IN, OSC_OUT, when PH01_REMAP =1, PH0/PH1 is general-purpose IO port.

7.5. Register definition

GPIO start address: 0x4001 0800

7.5.1. Port control register 0 (GPIOx_CTL0, x=A..I)

Address offset: 0x00

Reset value: 0x4444 4444

This register has to be accessed by word (32-bit).

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits	Fields	Descriptions
31:16	CRy	Port Clear bit y(y=0..15) These bits are set and cleared by software 0: No action on the corresponding OCTLy bit 1: Clear the corresponding OCTLy bit to 0
15:0	BOPy	Port Set bit y(y=0..15) These bits are set and cleared by software 0: No action on the corresponding OCTLy bit 1: Set the corresponding OCTLy bit to 1 **Note:** if CRy and BOPy are set at the same time, BOPy has priority.

7.5.6. Port bit clear register (GPIOx_BC, x=A..I)

Address offset: 0x14
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	CRy	Port Clear bit y(y=0..15) These bits are set and cleared by software 0: No action on the corresponding OCTLy bit 1: Clear the corresponding OCTLy bit to 0

7.5.7. Port configuration lock register (GPIOx_LOCK, x=A..I)

Address offset: 0x18
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															LKK
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits	Fields	Descriptions
31:17	Reserved	Must be kept at reset value
16	LKK	Lock sequence key It can only be setted using the Lock Key Writing Sequence. And can always be read. 0: GPIO_LOCK register is not locked and the port configuration is not locked. 1: GPIO_LOCK register is locked until an MCU reset.. LOCK key configuration sequence Write 1→Write 0→Write 1→ Read 0→ Read 1 **Note:** The value of LK[15:0] must hold during the LOCK Key Writing sequence.
15:0	LKy	Port Lock bit y(y=0..15) These bits are set and cleared by software 0: The corresponding bit port configuration is not locked 1: The corresponding bit port configuration is locked when LKK bit is “1”

7.5.8. Event control register (AFIO_EC)

Address offset: 0x00

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

rw	rw		rw	rw		rw		rw		rw		rw	rw	rw	rw

Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30	PTP_PPS_REMAP	Ethernet PTP PPS remapping This bit is set and cleared by software. It enables the Ethernet MAC_PPS to be output on the PB5 pin 0: PPT_PPS not output PB5 pin 1: PPT_PPS is output on PB5 pin
29	TIMER1ITI1_REMAP	TIMER1 internal trigger 1 remapping These bits are set and cleared by software. It controls the TMER1_ITI1

		internal mapping 0: Connect TIMER1_ITI1 internally to the Ethernet PTP output for calibration purposes 1: Connect USB OTG SOF (Start of Frame) output TIMER1_ITI1 for calibration purposes
28	SPI2_REMAP	SPI2/I2S2 remapping This bit is set and cleared by software. 0: No remap (SPI2_NSS-I2S2_WS/PA15, SPI2_SCK-I2S2_CK/PB3, SPI2_MISO/PB4, SPI2_MOSI-I2S_SD/PB5) 1: Full remap (SPI2_NSS-I2S2_WS/PA4, SPI2_SCK-I2S2_CK/PC10, SPI2_MISO/PC11, SPI2_MOSI-I2S_SD/PC12)
27	Reserved	Must be kept at reset value
26:24	SWJ_CFG[2:0]	Serial wire JTAG configuration These bits are write-only (when read,the value is undefined).They are used to configure the SWJ and trace alternate function I/Os. The SWJ(Serial Wire JTAG) supports JTAG or SWD access to the Cortex debug port. The default state after reset is SWJ ON without trace.This allows JTAG or SW mode to be enabled by sending a specific sequence on the JTMS/JTCK pin 000: Full SWJ(JTAG-DP +SW-DP): Reset State 001: Full SWJ(JTAG-DP +SW-DP): but without NJTRST 010: JTAG-DP Disabled and SW-DP Enabled 100: JTAG-DP Disabled and SW-DP Disabled Other combinations: no effect
23	ENET_PHY_SEL	Ethernet MII or RMII PHY selection This bit is set and cleared by software.It configures the Ethernet MAC internally for use with an external MII or RMII PHY. 0:Configure Ethernet MAC for connection with an MII PHY 1:Configure Ethernet MAC for connection with an RMII PHY
22	CAN1_REMAP	CAN1 I/O remapping This bit is set and cleared by software.It controls the CAN1_TX and CAN1_RX pins 0: No remap (CAN1_RX/PB12,CAN_TX/PB13) 1: Remap (CAN1_RX/PB5,CAN_TX/PB6)
21	ENET_REMAP	Ethernet MAC I/O remapping This bit is set and cleared by software.It controls the Ethernet MAC connections with PHY 0: No remap (RX_DV-CRS_DV/PA7,RXD0/PC4,RXD1/PC5,RXD2/PB0, RXD3/PB1) 1: Remap (RX_DV-CRS_DV/PD8,RXD0/PD9,RXD1/PD10,RXD2/PD11, RXD3/PD12)

20	ADC1_ETRGREG_REMAP	ADC 1 external trigger regular conversion remapping Set and cleared by software. The bit control the trigger input connected to ADC1 external trigger regular conversion. When this bit is reset, the ADC1 external trigger requlat conversion to EXTI11.When this bit is set, the ADC1 external event regular conversion is connected to TIM7_TRGO.
19	ADC1_ETRGINS_REMAP	ADC 1 external trigger inserted conversion remapping Set and cleared by software. The bit control the trigger input connected to ADC1 external trigger inserted conversion. When this bit is reset, the ADC1 external trigger inserted conversion to EXTI15.When this bit is set, the ADC1 external event inserted conversion is connected to TIM7_CH3.
18	ADC0_ETRGREG_REMAP	ADC 0 external trigger regular conversion remapping Set and cleared by software. The bit control the trigger input connected to ADC0 external trigger inserted conversion. When this bit is reset, the ADC0 external trigger inserted conversion to EXTI11.When this bit is set, the ADC0 external event inserted conversion is connected to TIM7_TRGO.
17	ADC0_ETRGINS_REMAP	ADC 0 external trigger inserted conversion remapping Set and cleared by software. The bit control the trigger input connected to ADC0 external trigger inserted conversion. When this bit is reset, the ADC0 external trigger inserted conversion to EXTI15.When this bit is set, the ADC0 external event inserted conversion is connected to TIM7_CH3.
16	TIMER4CH3_IREMAP	TIMER4 channel3 internal remapping Set and cleared by software.This bit controls the TIMER4_CH3 internal mapping. When reset timer TIMER4_CH3 is connected to PA3.When set the IRC40K internal clock connected to TIMER4_CH3 input for calibration purpose. 0: No remap 1: Remap
15	PD01_REMAP	Port D0/Port D1 mapping on OSC_IN/OSC_OUT This bit is set and cleared by software 0: Not remap 1: PD0 remapped on OSC_IN, PD1 remapped on OSC_OUT
14:13	CAN0_REMAP[1:0]	CAN0 alternate interface remapping These bits are set and cleared by software 00: No remap (CAN0_RX/PA11,CAN0_TX/PA12) 01: Not used 10: Partial remap (CAN0_RX/PB8,CAN0_TX/PB9) 11: Full remap (CAN0_RX/PD0,CAN0_TX/PD1)
12	TIMER3_REMAP	TIMER3 remapping This bit is set and cleared by software. 0: No remap (TIMER3_CH0/PB6,TIMER3_CH1/PB7,TIMER3_CH2/PB8,

		TIMER3_CH3/PB9) 1: Full remap (TIMER3_CH0/PD12,TIMER3_CH1/PD13, TIMER3_CH2/PD14,TIMER3_CH3/PD15)
11:10	TIMER2_REMAP [1:0]	TIMER2 remapping These bits are set and cleared by software 00: No remap (TIMER2_CH0/PA6,TIMER2_CH1/PA7,TIMER2_CH2/PB0, TIMER2_CH3/PB1) 01: Not used 10: Partial remap (TIMER2_CH0/PB4,TIMER2_CH1/PB5, TIMER2_CH2/PB0,TIMER2_CH3/PB1) 11: Full remap (TIMER2_CH0/PC6,TIMER2_CH1/PC7,TIMER2_CH2/PC8, TIMER2_CH3/PC9)
9:8	TIMER1_REMAP [1:0]	TIMER1 remapping These bits are set and cleared by software 00: No remap (TIMER1_CH0-TIMER1_ETI/PA0,TIMER1_CH1/PA1, TIMER1_CH2/PA2,TIMER1_CH3/PA3) 01: Partial remap 0 (TIMER1_CH0-TIMER1_ETI/PA15,TIMER1_CH1/PB3, TIMER1_CH2/PA2,TIMER1_CH3/PA3) 10: Partial remap 1 (TIMER1_CH0-TIMER1_ETI/PA0,TIMER1_CH1/PA1, TIMER1_CH2/PB10,TIMER1_CH3/PB11) 11: Full remap (TIMER1_CH0-TIMER1_ETI/PA15,TIMER1_CH1/PB3, TIMER1_CH2/PB10,TIMER1_CH3/PB11)
7:6	TIMER0_REMAP [1:0]	TIMER0 remapping These bits are set and cleared by software 00: No remap (TIMER0_ETI/PA12, TIMER0_CH0/ PA8, TIMER0_CH1/PA9, TIMER0_CH2/PA10,TIMER0_CH3/PA11, TIMER0_BKIN/PB12, TIMER0_CH0_ON/PB13, TIMER0_CH1_ON/PB14, TIMER0_CH2_ON/PB15) 01: Partial remap (TIMER0_ETI/PA12, TIMER0_CH0/ PA8, TIMER0_CH1/PA9,TIMER0_CH2/PA10,TIMER0_CH3/PA11, TIMER0_BKIN/PA6, TIMER0_CH0_ON/PA7, TIMER0_CH1_ON/PB0, TIMER0_CH2_ON/PB1) 10: Not used 11: Full remap (TIMER0_ETI/PE7, TIMER0_CH0/ PE9, TIMER0_CH1/PE11,TIMER0_CH2/PE13,TIMER0_CH3/PE14, TIMER0_BKIN/PE15, TIMER0_CH0_ON/PE8, TIMER0_CH1_ON/PE10, TIMER0_CH2_ON/PE12)
5:4	USART2_REMAP [1:0]	USART2 remapping These bits are set and cleared by software 00: No remap (USART2_TX/PB10, USART2_RX /PB11, USART2_CK/PB12,USART2_CTS/PB13, USART2_RTS/PB14) 01: Partial remap (USART2_TX/PC10, USART2_RX /PC11, USART2_CK/PC12,USART2_CTS/PB13, USART2_RTS/PB14)

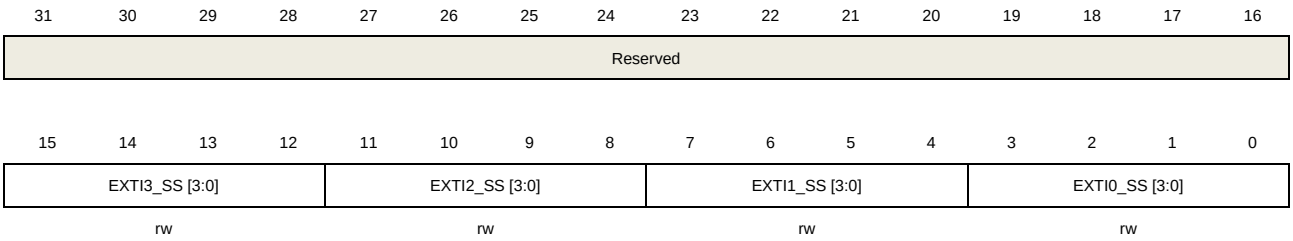
		10: Not used 11: Full remap (USART2_TX/PD8, USART2_RX /PD9, USART2_CK/PD10,USART2_CTS/PD11, USART2_RTS/PD12)
3	USART1_REMAP	USART1 remapping This bit is set and cleared by software 0: No remap (USART1_CTS/PA0, USART1_RTS/PA1,USART1_TX/PA2, USART1_RX /PA3, USART1_CK/PA4) 1: Remap (USART1_CTS/PD3, USART1_RTS/PD4,USART1_TX/PD5, USART1_RX /PD6, USART1_CK/PD7)
2	USART0_REMAP	USART0 remapping This bit is set and cleared by software 0: No remap (USART0_TX/PA9, USART0_RX /PA10) 1: Remap (USART0_TX/PB6, USART0_RX /PB7)
1	I2C0_REMAP	I2C0 remapping This bit is set and cleared by software 0: No remap (I2C0_SCL/PB6, I2C0_SDA /PB7) 1: Remap (I2C0_SCL/PB8, I2C0_SDA /PB9)
0	SPI0_REMAP	SPI0 remapping This bit is set and cleared by software 0: No remap (SPI0_NSS/PA4, SPI0_SCK /PA5, SPI0_MISO /PA6, SPI0_MOSI /PA7, SPI0_IO2 /PA2, SPI0_IO3 /PA3) 1: Remap (SPI0_NSS/PA15, SPI0_SCK /PB3, SPI0_MISO /PB4, SPI0_MOSI /PB5, SPI0_IO2 /PB6, SPI0_IO3 /PB7)

7.5.10. EXTI sources selection register 0 (AFIO_EXTISS0)

Address offset: 0x08

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).



Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:12	EXTI3_SS [3:0]	EXTI 3 sources selection

		0000: PA3 pin 0001: PB3 pin 0010: PC3 pin 0011: PD3 pin 0100: PE3 pin 0101: PF3 pin 0110: PG3 pin 0111: PH3 pin 1000: PI3 pin Other configurations are reserved.
11:8	EXTI2_SS [3:0]	EXTI 2 sources selection 0000: PA2 pin 0001: PB2 pin 0010: PC2 pin 0011: PD2 pin 0100: PE2 pin 0101: PF2 pin 0110: PG2 pin 0111: PH2 pin 1000: PI2 pin Other configurations are reserved.

Other configurations are reserved.

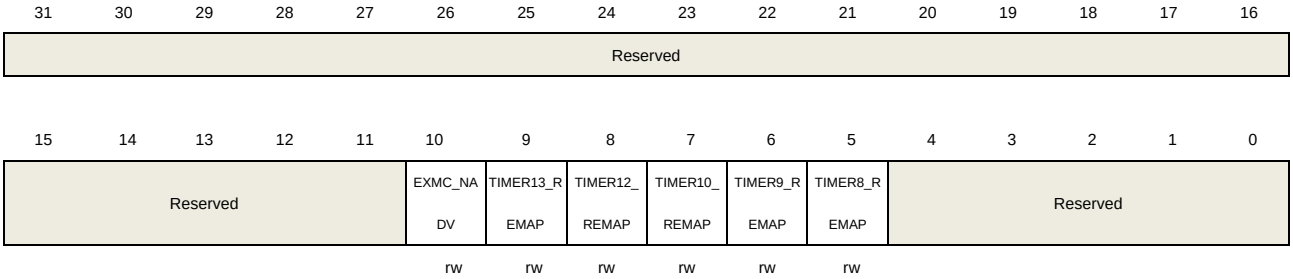
7.5.14. AFIO port configuration register 1 (AFIO_PCF1)

Address offset: 0x1C
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).



Bits	Fields	Descriptions
31:11	Reserved	Must be kept at reset value
10	EXMC_NADV	EXMC_NADV connect/disconnect This bit is set and cleared by software, it controls the use of optional EXMC_NADV signal. 0: The NADV signal is connected to the output(default) 1: The NADV signal is not connected. The I/O pin can be used by another peripheral.
9	TIMER13_REMAP	TIMER13 remapping This bit is set and cleared by software, it controls the mapping of the TIMER13_CH0 alternate function onto the GPIO ports 0: No remap (PA7) 1: Remap (PF9)
8	TIMER12_REMAP	TIMER12 remapping This bit is set and cleared by software, it controls the mapping of the TIMER12_CH0 alternate function onto the GPIO ports 0: No remap (PA6) 1: Remap (PF8)
7	TIMER10_REMAP	TIMER10 remapping This bit is set and cleared by software, it controls the mapping of the TIMER10_CH0 alternate function onto the GPIO ports

		0: No remap (PB9) 1: Remap (PF7)
6	TIMER9_REMAP	TIMER9 remapping This bit is set and cleared by software, it controls the mapping of the TIMER9_CH0 alternate function onto the GPIO ports 0: No remap (PB8) 1: Remap (PF6)
5	TIMER8_REMAP	TIMER8 remapping This bit is set and cleared by software, it controls the mapping of the TIMER8_CH0 and TIMER8_CH1 alternate function onto the GPIO ports 0: No remap (TIMER8_CH0 on PA2 and TIMER8_CH1 on PA3) 1: Remap (TIMER8_CH0 on PE5 and TIMER8_CH1 on PE6)
4:0	Reserved	Must be kept at reset value

7.5.15. AFIO port configuration register 2 (AFIO_PCF2)

Address offset: 0x3C

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).

8. CRC calculation unit (CRC)

8.1. Overview

A cyclic redundancy check (CRC) is an error-detecting code commonly used in digital networks and storage devices to detect accidental changes to raw data.

This CRC calculation unit can be used to calculate 32 bit CRC code with fixed polynomial.

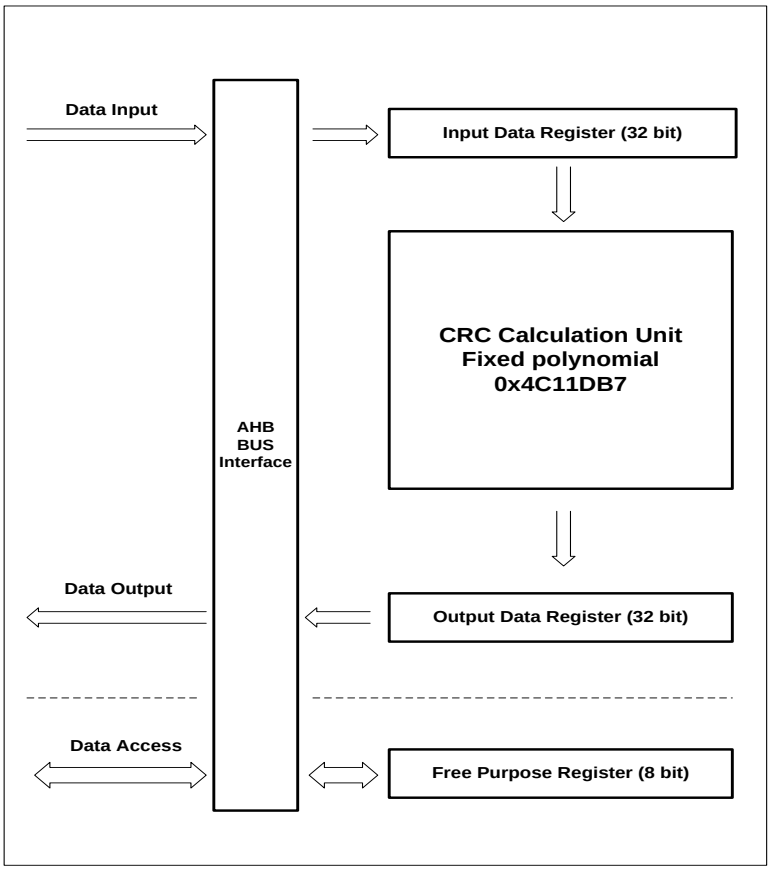
8.2. Characteristics

- 32-bit data input and 32-bit data output. Calculation period is 4 AHB clock cycles for 32-bit input data size from data entered to the calculation result available.
- Free 8-bit register is unrelated to calculation and can be used for any other goals by any other peripheral devices.
- Fixed polynomial: 0x4C11DB7

$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$

This 32-bit CRC polynomial is a common polynomial used in Ethernet.

Figure 8-1. Block diagram of CRC calculation unit



8.3. Function overview

- CRC calculation unit is used to calculate the 32-bit raw data, and CRC_DATA register will receive the raw data and store the calculation result.
  If the CRC_DATA register has not been cleared by software setting the CRC_CTL register, the new input raw data will be calculated based on the result of previous value of CRC_DATA.
  CRC calculation will spend 4 AHB clock cycles for 32-bit data size, during this period AHB will not be hanged because of the existence of the 32-bit input buffer.
- This module supplies an 8-bit free register CRC_FDATA.
  CRC_FDATA is unrelated to the CRC calculation, any value you write in will be read out at anytime.

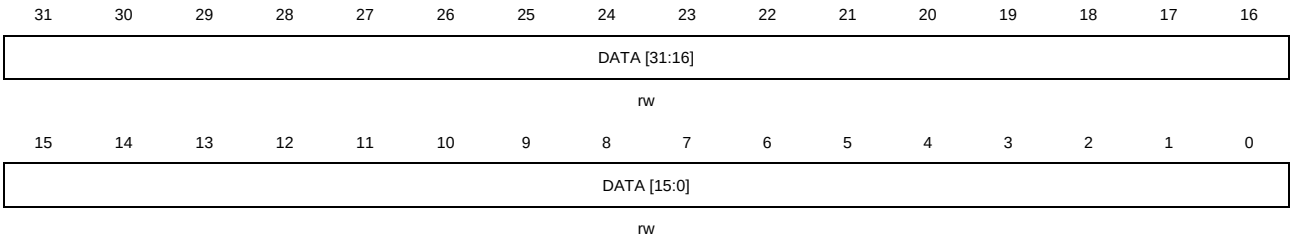
8.4. Register definition

CRC start address: 0x4002 3000

8.4.1. Data register (CRC_DATA)

Address offset: 0x00
Reset value: 0xFFFF FFFF

This register has to be accessed by word (32-bit).

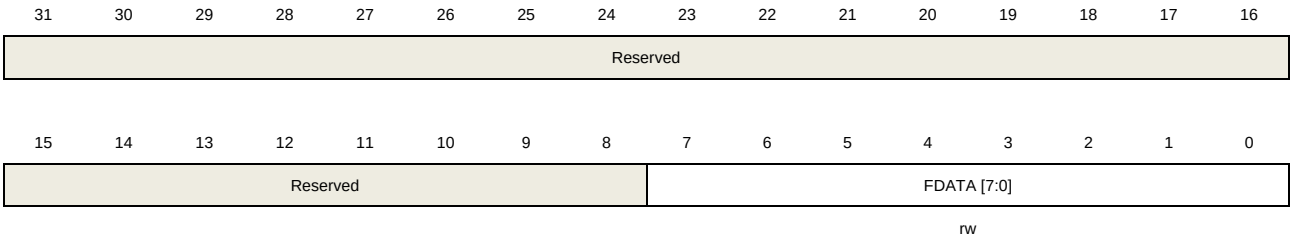


Bits	Fields	Descriptions
31:0	DATA [31:0]	CRC calculation result bits Software writes and reads. This register is used to calculate new data, and the register can be written the new data directly. Written value cannot be read because the read value is the previous CRC calculation result.

8.4.2. Free data register (CRC_FDATA)

Address offset: 0x04
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).



Bits	Fields	Descriptions
31:8	Reserved	Keep at reset value
7:0	FDATA [7:0]	Free Data Register bits

Software writes and reads.

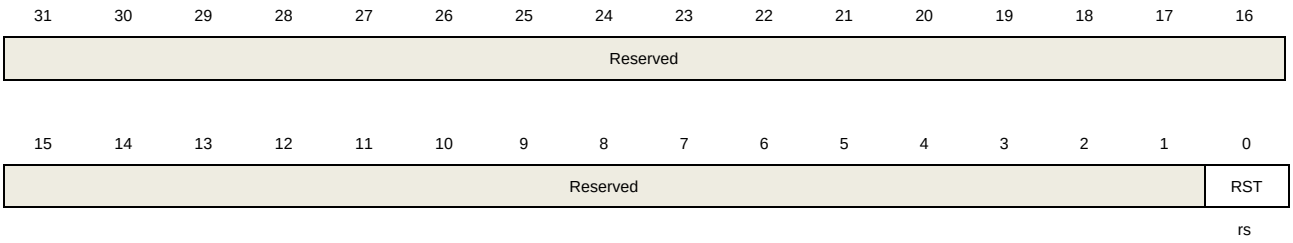
These bits are unrelated with CRC calculation. This byte can be used for any goal by any other peripheral. The CRC_CTL register will take no effect to the byte.

8.4.3. Control register (CRC_CTL)

Address offset: 0x08

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit).



Bits	Fields	Descriptions
31:1	Reserved	Keep at reset value
0	RST	Set this bit can reset the CRC_DATA register to the value of 0xFFFFFFFF then automatically cleared itself to 0 by hardware. This bit will take no effect to CRC_FDATA. Software writes and reads.

9. True random number generator (TRNG)

9.1. Overview

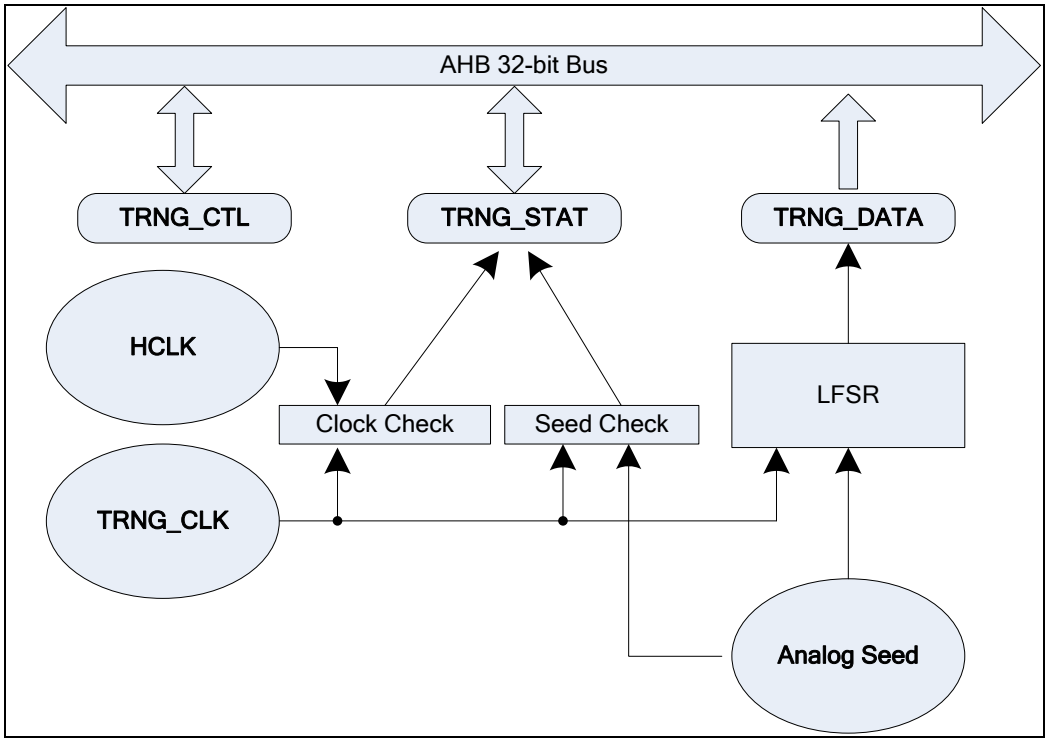
The true random number generator (TRNG) module can generate a 32-bit random value by using continuous analog noise.

9.2. Characteristics

- About 40 periods of TRNG_CLK are needed between two consecutive random numbers
- Disable TRNG module will significantly reduce the chip power consumption
- 32-bit random value seed is generated from analog noise, so the random number is a true random number.

9.3. Function overview

Figure 9-1. TRNG block diagram



The random number seed comes from analog circuit. This analog seed is then plugged into a linear feedback shift register (LFSR), where a 32-bit width random number is generated.

The analog seed is generated by several ring oscillators. The LFSR is driven by a configurable

TRNG_CLK (refer to ***Reset and clock unit (RCU)*** chapter), so that the quality of the generated random number depends on TRNG_CLK exclusively, no matter what HCLK frequency was set or not.

The 32-bit value of LFSR will transfer into TRNG_DATA register after a sufficient number of seeds have been sent to the LFSR.

At the same time, the analog seed and TRNG_CLK clock are monitored. When an analog seed error or a clock error occurs, the corresponding status bit in TRNG_STAT will be set and an interrupt is generated if the IE bit in TRNG_CTL is set.

9.3.1. Operation flow

The following steps are recommended for using TRNG block:

1). Enable the interrupt as necessary, so that when a random number or an error occurs, an interrupt will be generated.

2). Enable the TRNGEN bit.

3). When an interrupt occurs, check the status register TRGN_STAT, if SEIF=0, CEIF=0 and DRDY=1, then the random value in the data register could be read.

As required by the FIPS PUB 140-2, the first random data in data register should be saved but not be used. Every subsequent new random data should be compared to the previously random data. The data can only be used if it is not equal to the previously one.

9.3.2. Error flags

(1) Clock Error

When the TRNG_CLK frequency is lower than the 1/16 of HCLK, the CECS and CEIF bit will be set. In this case, the application should check TRNG_CLK and HCLK frequency configurations and then clear CEIF bit. Clock error will not impact the previous random data.

(2) Seed Error

When the analog seed is not changed or always changing during 64 TRNG_CLK periods, the SECS and SEIF bit will be set. In this case, the random data in data register should not be used. The application needs to clear the SEIF bit, then clear and set TRNGEN bit for restarting the TRNG.

9.4. Register definition

TRNG start address: 0x5006 0800

9.4.1. Control register (TRNG_CTL)

Address offset: 0x00
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												IE	TRNGEN	Reserved	
												rw	rw		

Bits	Fields	Descriptions
31:4	Reserved	Must be kept at reset value
3	IE	Interrupt enabled bit. This bit controls the generation of an interrupt when DRDY,SEIF or CEIF was set 0: TRNG Interrupt disable 1: TRNG Interrupt enable
2	TRNGEN	TRNG enabled bit. 0: TRNG module disable(reduce power consuming) 1: TRNG module enable
1:0	Reserved	Must be kept at reset value

9.4.2. Status register (TRNG_STAT)

Address offset: 0x04
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									SEIF	CEIF	Reserved		SECS	CECS	DRDY
									rc_w0	rc_w0			r	r	r

Bits	Fields	Descriptions
31:7	Reserved	Must be kept at reset value
6	SEIF	Seed error interrupt flag This bit will be set if more than 64 consecutive same bit or more than 32 consecutive 01(or 10) changing are detected. 0: No fault detected 1: Seed error has been detected. The bit is cleared by writing 0.
5	CEIF	Clock error interrupt flag This bit will be set if TRNG_CLK frequency is lower than 1/16 HCLK frequency. 0: No fault detected 1: Clock error has been detected. The bit is cleared by writing 0.
4:3	Reserved	Must be kept at reset value
2	SECS	Seed error current status 0: Seed error is not detected at current time. In case of SEIF=1 and SECS=0, it means seed error has been detected before but now is recovered. 1: Seed error is detected at current time if more than 64 consecutive same bits or more than 32 consecutive 01(or 10) changing are detected
1	CECS	Clock error current status 0: Clock error is not detected at current time. In case of CEIF=1 and CECS=0, it means clock error has been detected before but now is recovered. 1: Clock error is detected at current time. TRNG_CLK frequency is lower than 1/16 HCLK frequency
0	DRDY	Random Data ready status bit. This bit is cleared by reading the TRNG_DATA register and set when a new random number is generated. 0: The content of TRNG data register is not available. 1: The content of TRNG data register is available

9.4.3. Data register (TRNG_DATA)

Address offset: 0x08

Reset value: 0x0000 0000

Application must make sure DRDY is set before reading this register

This register has to be accessed by word (32-bit)

10. Cryptographic Acceleration Unit (CAU)

10.1. Overview

The cryptographic acceleration unit (CAU) is used to encipher and decipher data with DES, Triple-DES or AES (128, 192, or 256) algorithms. It is fully compliant implementation of the following standards:

- The Data Encryption Standard (DES) and the Triple Data Encryption Algorithm (TDEA) are announced by Federal Information Processing Standards Publication (FIPS) 46-3, October 25, 1999. It follows the American National Standards Institute (ANSI) X9.52 standard.
- The Advanced Encryption Standard (AES) is announced by Federal Information Processing Standards Publication 197, November 26, 2001.

DES/TDES/AES algorithms with different key sizes are supported to perform data encryption and decryption in the CAU in multiple modes.

The CAU is a 32-bit peripheral, DMA transfer is supported and data can be accessed in the input and output FIFO.

10.2. Characteristics

- DES, TDES and AES encryption/decryption algorithms are supported.
- Multiple modes are supported respectively in DES, TDES and AES, including Electronic codebook (ECB), Cipher block chaining (CBC) and Counter mode (CTR).
- DMA transfer for incoming and outgoing data is supported.

DES/TDES

- Supports the ECB and CBC chaining algorithms
- two 32-bit initialization vectors (IV) are used in CBC mode
- 8*32-bit input and output FIFO
- Multiple data types are supported, including No swapping, Half-word swapping Byte swapping and Bit swapping
- Data are transferred by DMA, CPU during interrupts, or without both of them

AES

- Supports the ECB, CBC and CTR chaining algorithms
- Supports 128-bit, 192-bit and 256-bit keys

- four 32-bit initialization vectors (IV) are used in CBC and CTR modes
- 8*32-bit input and output FIFO
- Multiple data types are supported, including No swapping, Half-word swapping Byte swapping and Bit swapping
- Data can be transferred by DMA, CPU during interrupts, or without both of them

10.3. CAU data type and initialization vectors

10.3.1. Data type

The cryptographic acceleration unit receives data of 32 bits at a time, while they are processed in 64/128 bits for DES/AES algorithms. For each data block, according to the data type, the data could be bit/byte/half-word/no swapped before they are transferred into the cryptographic acceleration processor. The same swapping operation should be also performed on the processor output data before they are collected. Note the least-significant data always occupies the lowest address location no matter which data type is configured, because the system memory is little-endian.

Figure 10-1. DATAM No swapping and Half-word swapping and ***Figure 10-2. DATAM Byte swapping and Bit swapping*** illustrate the 128-bit AES block data swapping according to different data types. (For DES, the data block is two 32-bit words, please refer to the first two words data swapping in the figure).

Figure 10-1. DATAM No swapping and Half-word swapping

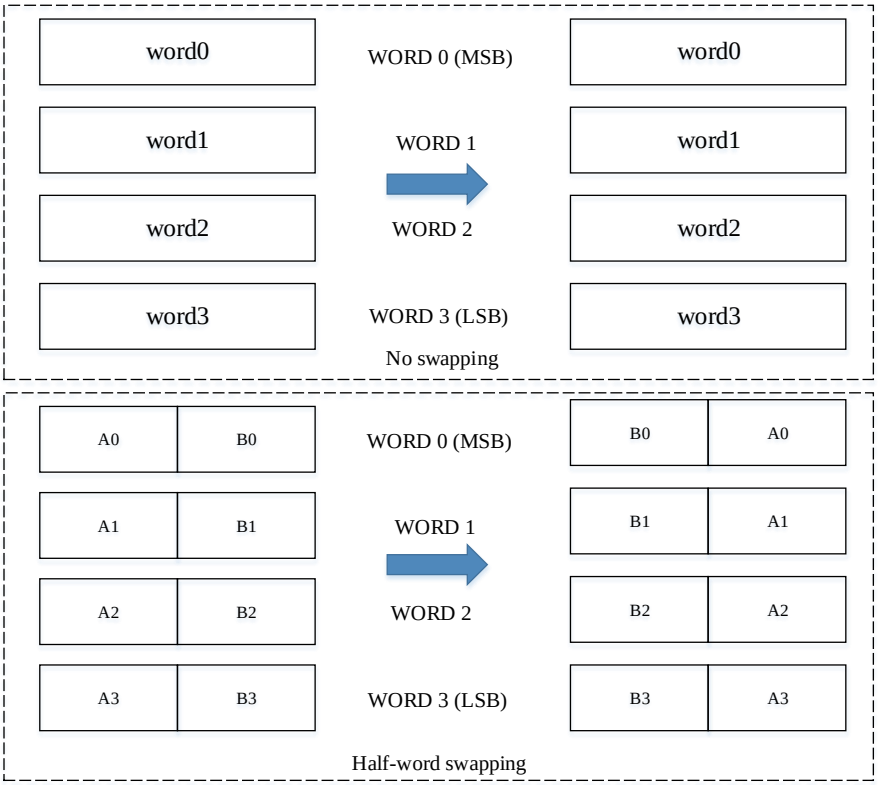

Figure 10-2. DATAM Byte swapping and Bit swapping

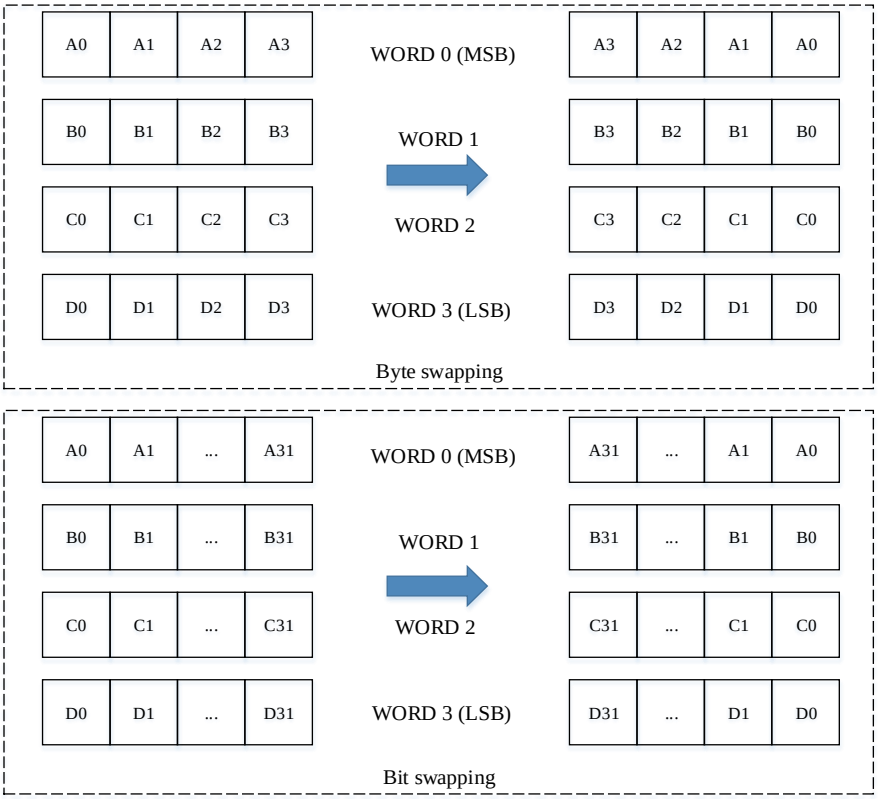


10.3.2. Initialization vectors

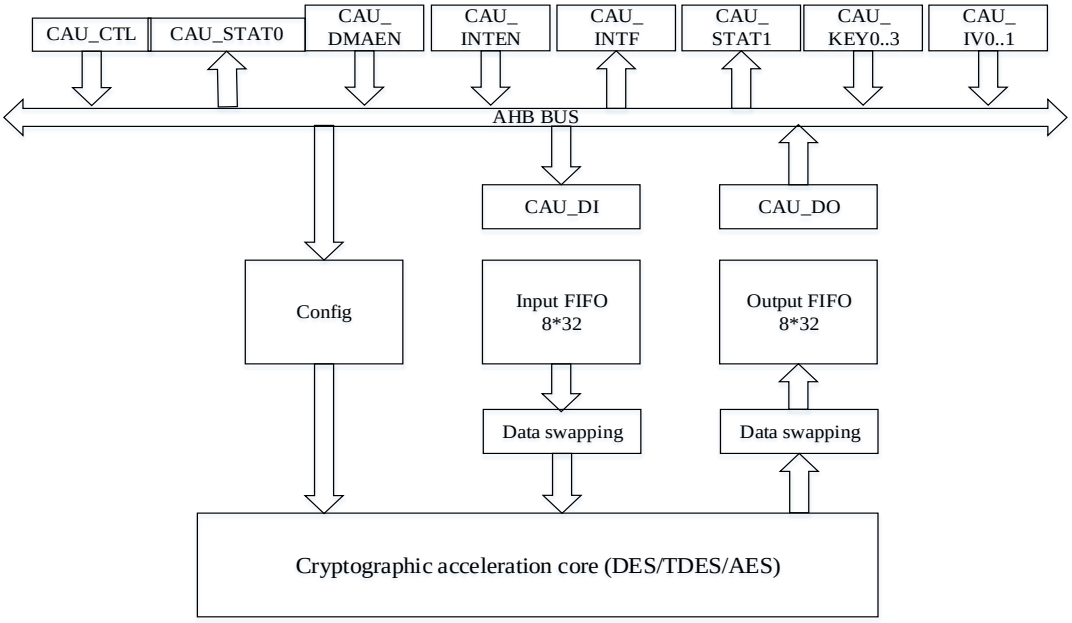
The initialization vectors are used in CBC and CTR modes to XOR with data blocks. They are independent of plaintext and ciphertext, and the DATAM value will not affect them. Note the initialization vector registers CAU_IV0..1(H/L) can only be written when BUSY is 0, otherwise the write operations are invalid.

10.4. Cryptographic acceleration processor

The cryptographic acceleration unit implements DES and AES acceleration processors, which are detailed described in section ***DES/TDES cryptographic acceleration processor*** and ***AES cryptographic acceleration processor***.

Figure 10-3. CAU diagram shows the block diagram of the cryptographic acceleration unit.

Figure 10-3. CAU diagram



10.4.1. DES/TDES cryptographic acceleration processor

The DES/TDES cryptographic acceleration processor contains the DES algorithm (DEA), cryptographic keys (1 for DES algorithm and 3 for TDES algorithm), and initialization vectors in CBC mode.

DES/TDES key

[KEY1] is used in DES and [KEY3 KEY2 KEY1] are used in TDES respectively.
When TDES algorithm is configured, three different keying options are allowed:

1. Three same keys

The three keys KEY3, KEY2 and KEY1 are completely equal, which means KEY3=KEY2=KEY1. FIPS PUB 46-3 – 1999 (and ANSI X9.52 -1998) refers to this option. It is easy to understand that this mode is equivalent to DES.

2. Two different keys

In this option, KEY2 is different from KEY1, and KEY3 is equal to KEY1, which means, KEY1 and KEY2 are independent while KEY3= KEY1. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option.

3. Three different keys

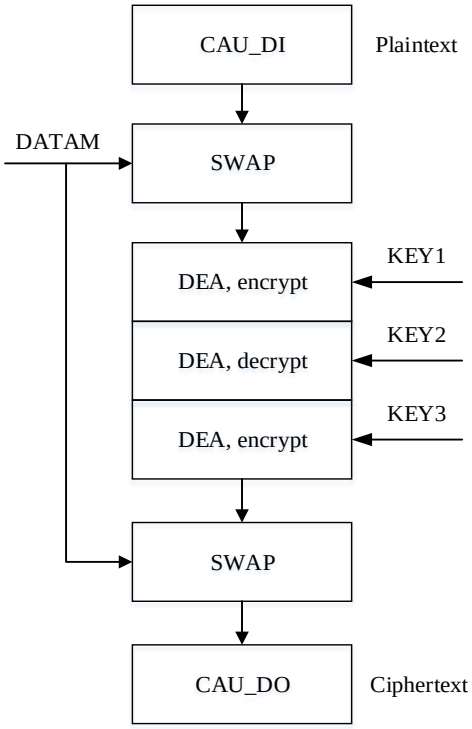
In this option, KEY1, KEY2 and KEY3 are completely independent. FIPS PUB 46-3 -1999 (and ANSI X9.52 – 1998) refers to this option.

More information of the thorough explanation of the key used in the DES/TDES please refer to FIPS PUB 46-3 (and ANSI X9.52 -1998), and the explanation process is omitted in this manual.

DES/TDES ECB encryption

The 64-bit input plaintext is first obtained after data swapping according to the data type. When the TDES algorithm is configured, the input data block is read in the DEA and encrypted using KEY1. The output is fed back directly to next DEA and then decrypted using KEY2. After that, the output is fed back directly to the last DEA and encrypted with KEY3. The output after above processes is then swapped back according to the data type again, and a 64-bit ciphertext is produced. When the DES algorithm is configured, the result of the first DEA encrypted using KEY1 is swapped directly according to the data type, and a 64-bit ciphertext is produced. The procedure of DES/TDES ECB mode encryption is illustrated in ***Figure 10-4. DES/TDES ECB encryption***.

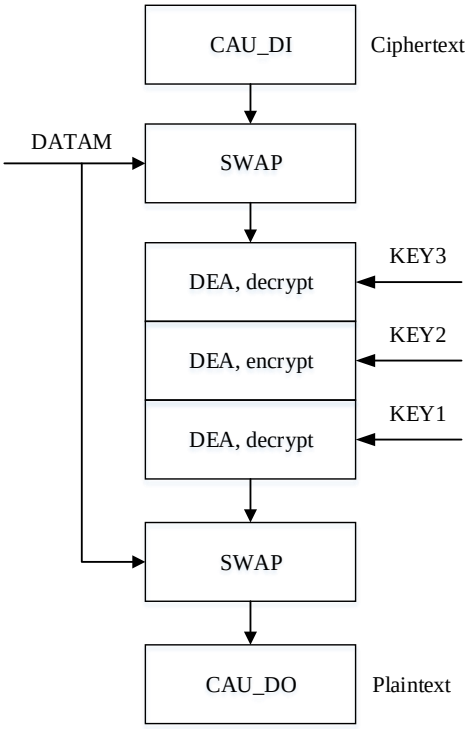
Figure 10-4. DES/TDES ECB encryption



DES/TDES ECB decryption

The 64-bit input ciphertext is first obtained after data swapping according to the data type. When the TDES algorithm is configured, the input data block is read in the DEA and decrypted using KEY3. The output is fed back directly to next DEA and then encrypted using KEY2. After that, the output is fed back directly to the last DEA and decrypted with KEY1. The output after above process is then swapped back according to the data type again, and a 64-bit plaintext is produced. When the DES algorithm is configured, the result of the first DEA decrypted using KEY1 is swapped directly according to the data type, and a 64-bit plaintext is produced. The procedure of DES/TDES ECB mode decryption is illustrated in ***Figure 10-5. DES/TDES ECB decryption***.

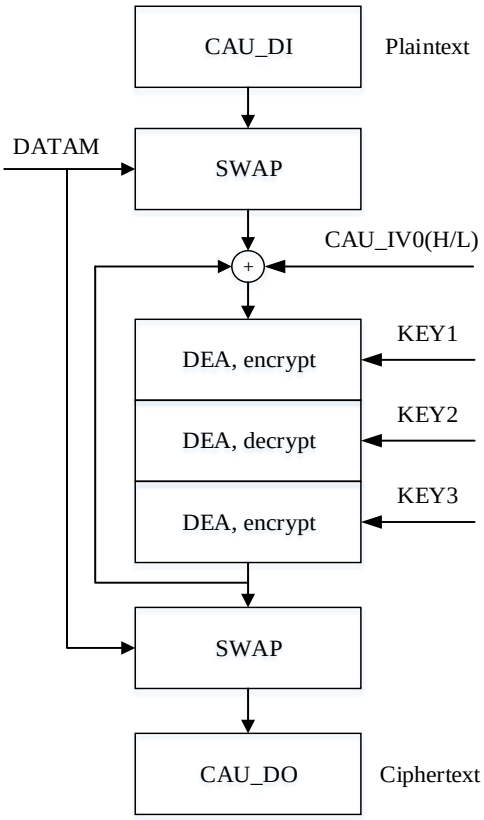
Figure 10-5. DES/TDES ECB decryption



DES/TDES CBC encryption

The input data of the DEA block in CBC mode consists of two aspects: the input plaintext after data swapping according to the data type, and the initialization vectors. When the TDES algorithm is configured, the XOR result of the swapped plaintext data block and the 64-bit initialization vector CAU_IV0..1 is read in the DEA and encrypted using KEY1. The output is fed back directly to next DEA and then decrypted using KEY2. After that, the output is fed back directly to the last DEA and encrypted with KEY3. The result is then used as the next initialization vector and exclusive-ORed with the next plaintext data block to process next encryption. The above operations are repeated until the last plaintext block is encrypted. Note if the plaintext message does not consist of an integral number of data blocks, the final partial data block should be encrypted in a specified manner. At last, the output ciphertext is also obtained after data swapping according to the data type. When the DES algorithm is configured, the state and process of the second and third block of DEA should be omitted. The procedure of DES/TDES CBC mode encryption is illustrated in ***Figure 10-6. DES/TDES CBC encryption***.

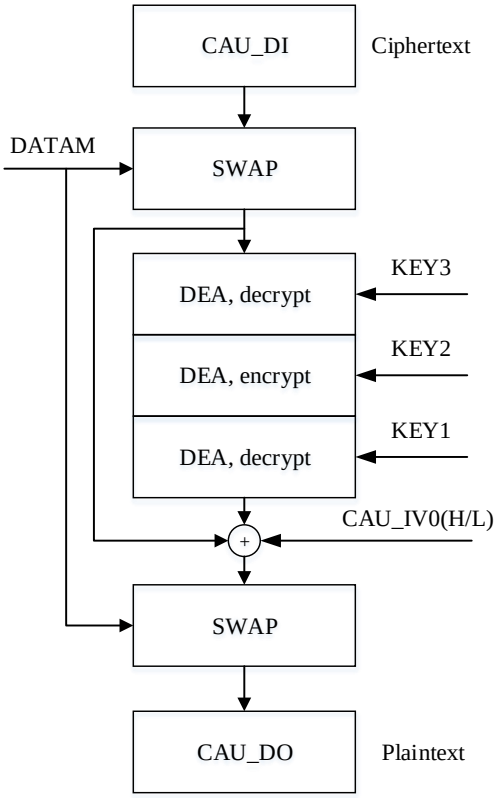
Figure 10-6. DES/TDES CBC encryption



DES/TDES CBC decryption

In DES/TDES CBC decryption, when the TDES algorithm is configured, the first ciphertext block is used directly after data swapping according to the data type, it is read in the DEA and decrypted using KEY3. The output is fed back directly to next DEA and then encrypted using KEY2. After that, the output is fed back directly to the last DEA and decrypted with KEY1. The first result of above process is then XORed with the initialization vector which is the same as that used during encryption. At the same time, the first ciphertext is then used as the next initialization vector and exclusive-ORed with the next result after DEA blocks. The above operations are repeated until the last ciphertext block is decrypted. Note if the ciphertext message does not consist of an integral number of data blocks, the final partial data block should be decrypted in a specified manner same to that in encryption. At last, the output plaintext is also obtained after data swapping according to the data type. When the DES algorithm is configured, the state and process of the second and third block of DEA should also be omitted. The procedure of DES/TDES CBC mode decryption is illustrated in ***Figure 10-7. DES/TDES CBC decryption***.

Figure 10-7. DES/TDES CBC decryption



10.4.2. AES cryptographic acceleration processor

The AES cryptographic acceleration processor consists of three components, including the AES algorithm (AEA), multiple keys and the initialization vectors or Nonce.

Three lengths of AES keys are supported: 128, 192 and 256 bits, and different initialization vectors or nonce are used depends on the operation mode.

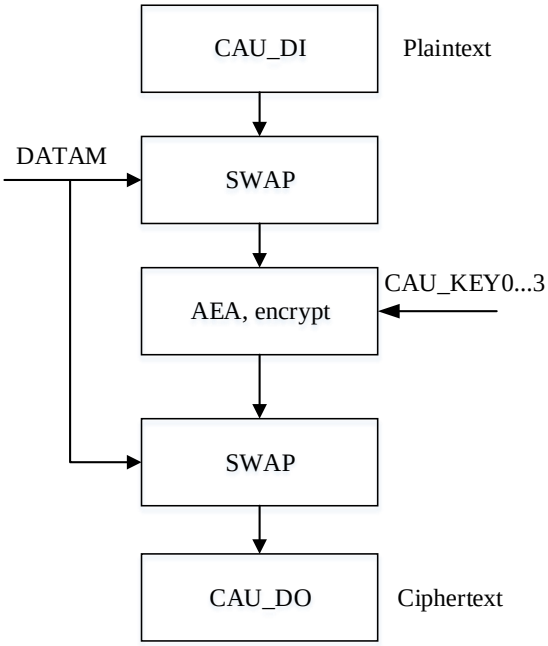
The AES key is used as [KEY3 KEY2] when the key size is configured as 128, [KEY3 KEY2 KEY1] when the key size is configured as 192 and [KEY3 KEY2 KEY1 KEY0] when the key size is configured as 256.

The thorough explanation of the key used in the AES is provided in FIPS PUB 197 (November 26, 2001), and the explanation process is omitted in this manual.

AES-ECB mode encryption

The 128-bit input plaintext is first obtained after data swapping according to the data type. The input data block is read in the AEA and encrypted using the 128, 192 or 256 -bit key. The output after above process is then swapped back according to the data type again, and a 128-bit ciphertext is produced and stored in the out FIFO. The procedure of AES ECB mode encryption is illustrated in ***Figure 10-8. AES ECB encryption***.

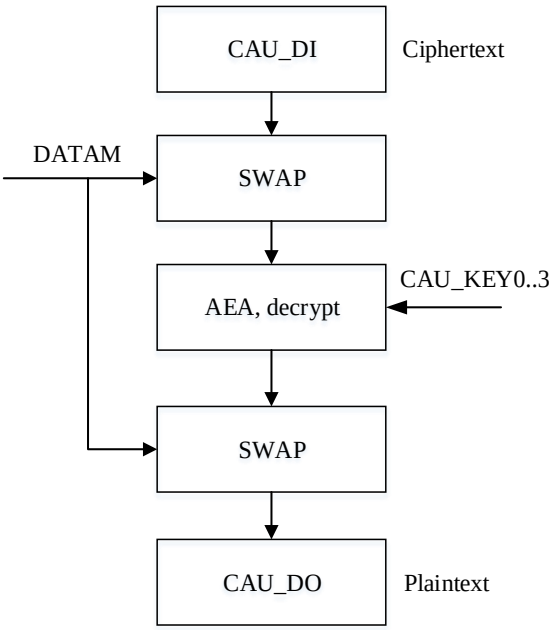
Figure 10-8. AES ECB encryption



AES-ECB mode decryption

First of all, the key derivation must be completed to prepare the decryption keys, the input key of the key schedule is the same to that used in encryption. The last round key obtained from the above operation is then used as the first round key in the decryption. After the key derivation, the 128-bit input ciphertext is first obtained after data swapping according to the data type. The input data block is read in the AEA and decrypted using keys prepared above. The output is then swapped back according to the data type again, and a 128-bit plaintext is produced. The procedure of AES ECB mode decryption is illustrated in ***Figure 10-9. AES ECB decryption***.

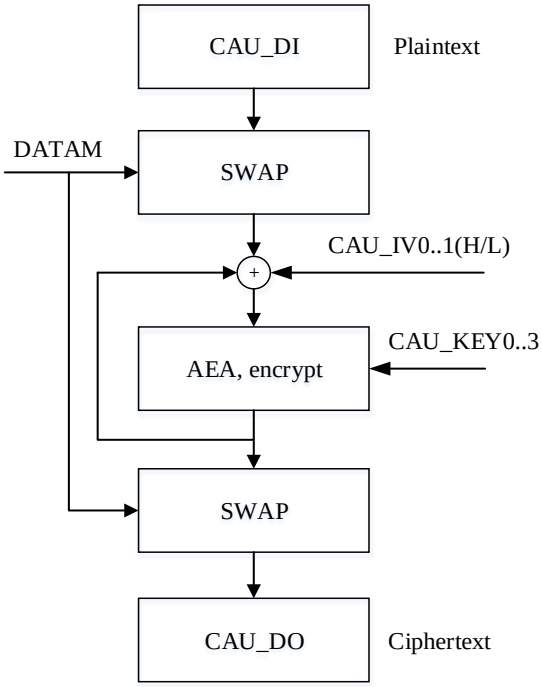
Figure 10-9. AES ECB decryption



AES-CBC mode encryption

The input data of the AEA block in CBC mode consists of two aspects: the input plaintext after data swapping according to the data type, and the initialization vectors. The XOR result of the swapped plaintext data block and the 128-bit initialization vector CAU_IV0..1 is read in the AEA and encrypted using the 128-, 192-, 256-bit key. The result is then used as the next initialization vector and exclusive-ORed with the next plaintext data block to process next encryption. The above operations are repeated until the last plaintext block is encrypted. Note if the plaintext message does not consist of an integral number of data blocks, the final partial data block should be encrypted in a specified manner. At last, the output ciphertext is also obtained after data swapping according to the data type. The procedure of AES CBC mode encryption is illustrated in ***Figure 10-10. AES CBC encryption***.

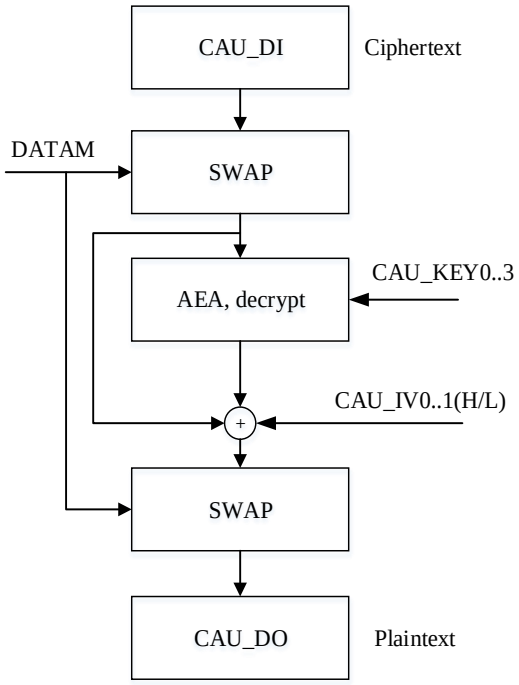
Figure 10-10. AES CBC encryption



AES-CBC mode decryption

Similar to that in AES-ECB mode decryption, the key derivation also must be completed first to prepare the decryption keys, the input of the key schedule should be the same to that used in encryption. The last round key obtained from the above operation is then used as the first round key in the decryption. After the key derivation, the 128-bit input ciphertext is first obtained after data swapping according to the data type. The input data block is read in the AEA and decrypted using keys prepared above. At the same time, the first ciphertext is then used as the next initialization vector and exclusive-ORed with the next result after AEA blocks (The first initialization is obtained directly from the CAU_IV0..1 registers). The above operations are repeated until the last ciphertext block is decrypted. Note if the ciphertext message does not consist of an integral number of data blocks, the final partial data block should be decrypted in a specified manner same to that in encryption. At last, the output plaintext is also obtained after data swapping according to the data type. The procedure of AES CBC mode decryption is illustrated in ***Figure 10-11. AES CBC decryption***.

Figure 10-11. AES CBC decryption



AES-CTR mode

In counter mode, a counter is used in addition with a nonce value to be encrypted and decrypted in AEA, and the result will be used for the XOR operation with the plaintext or the ciphertext. As the counter is incremented from the same initialized value for each block in encryption and decryption, the key schedule during the encryption and decryption are the same. Then decryption operation acts exactly in the same way as the encryption operation. Only the 32-bit LSB of the 128-bit initialization vector represents the counter, which means the other 96 bits are unchanged during the operation, and the initial value should be set to 1. Nonce is 32-bit single-use random value and should be updated to each communication block. And the 64-bit initialization vector is used to ensure that a given value is used only once for a given key. ***Figure 10-12. Counter block structure*** illustrates the counter block structure and ***Figure 10-13. AES CTR encryption/decryption*** shows the AES CTR encryption/decryption.

Figure 10-12. Counter block structure

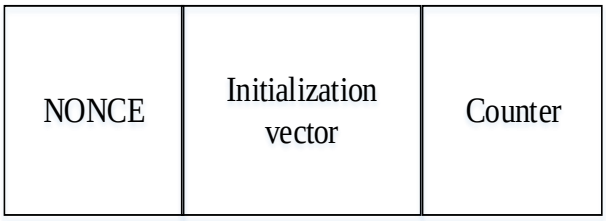


Figure 10-13. AES CTR encryption/decryption

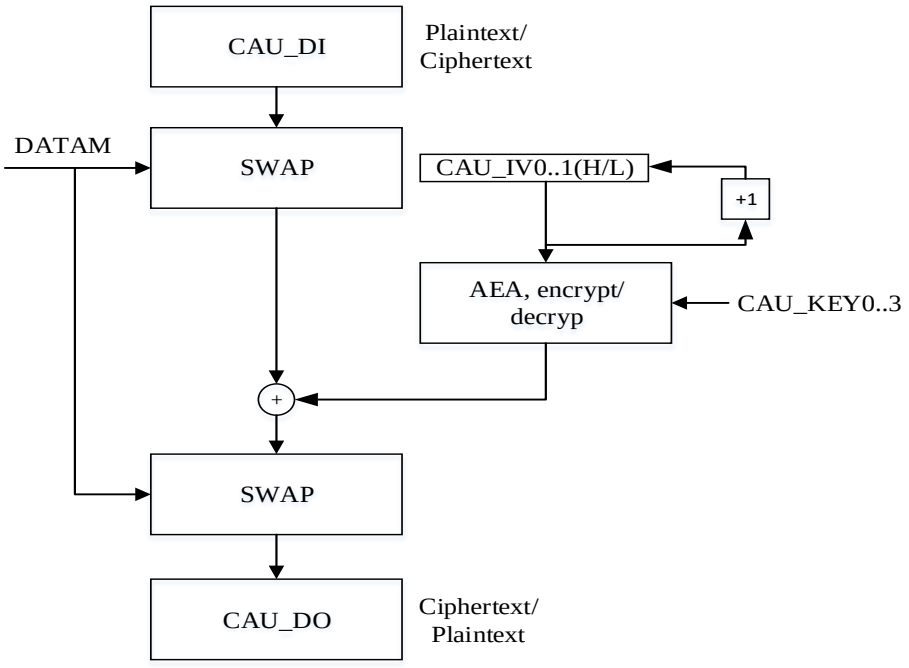


10.5. Operating modes

Encryption

1. Disable the CAU by resetting the CAUEN bit in the CAU_CTL register
2. Select and configure the key length with the KEYM bits in the CAU_CTL register if AES algorithm is chosen.
3. Configure the CAU_KEY0..3(H/L) registers according to the algorithm
4. Configure the DATAM bit in the CAU_CTL register to select the data swapping type
5. Configure the algorithm (DES/TDES/AES) and the chaining mode (ECB/CBC/CTR) by writing the ALGM bit in the CAU_CTL register
6. Configure the encryption direction by writing 0 to the CAUDIR bit in the CAU_CTL register.
7. Configure the initialization vectors by writing the CAU_IV0..1 registers
8. Flush the input FIFO and output FIFO by configure the FFLUSH bit in the CAU_CTL register when CAUEN is 0.
9. Enable the CAU by set the CAUEN bit as 1 in the CAU_CTL register.
10. If the INF bit in the CAU_STAT0 register is 1, then write data blocks into the CAU_DI register. The data can be transferred by DMA/CPU during interrupts/no DMA or interrupts.
11. Wait for ONE bit in the CAU_STAT0 register is 1 then read the CAU_DO registers. The output data can also be transferred by DMA/CPU during interrupts/no DMA or interrupts.
12. Repeat steps 10, 11 until all data blocks has been encrypted.

Decryption

1. Disable the CAU by resetting the CAUEN bit in the CAU_CTL register
2. Select and configure the key length with the KEYM bits in the CAU_CTL register if AES algorithm is chosen.
3. Configure the CAU_KEY0..3(H/L) registers according to the algorithm
4. Configure the DATAM bit in the CAU_CTL register to select the data swapping type
5. Configure the ALGM bits to “111” in the CAU_CTL register to complete the key derivation
6. Enable the CAU by set the CAUEN bit as 1
7. Wait until the BUSY and CAUEN bit return to 0 to make sure that the decryption keys are prepared
8. Configure the algorithm (DES/TDES/AES) and the chaining mode (ECB/CBC/CTR) by writing the ALGM bit in the CAU_CTL register
9. Configure the decryption direction by writing 1 to the CAUDIR bit in the CAU_CTL register.
10. Configure the initialization vectors by writing the CAU_IV0..1 registers
11. Flush the input FIFO and output FIFO by configure the FFLUSH bit in the CAU_CTL register when CAUEN is 0.
12. Enable the CAU by set the CAUEN bit as 1 in the CAU_CTL register.
13. If the INF bit in the CAU_STAT0 register is 1, then write data blocks into the CAU_DI register. The data can be transferred by DMA/CPU during interrupts/no DMA or interrupts.
14. Wait for ONE bit in the CAU_STAT0 register is 1, then read the CAU_DO registers. The output data can also be transferred by DMA/CPU during interrupts/no DMA or interrupts.
15. Repeat steps 13, 14 until all data blocks has been decrypted.

10.6. CAU DMA interface

The DMA can be used to transfer data blocks with the interface of the cryptographic acceleration unit. The operations can be controlled by the CAU_DMAEN register. DMAIEN is used to enable the DMA request during the input phase, then a word is written into CAU_DI from DMA. DMAOEN is used to enable the DMA request during the output phase, then a word is read from the CAU.

Single and Burst transfers are both supported to ensure the data transfer if the number of words is not an integral multiple of burst size. Note the DMA controller should be configured to perform burst of 4 words or less to make sure no data will be lost. DMA channel for output data has a higher priority than that channel for input data so that the output FIFO can be empty earlier than that the input FIFO is full.

10.7. CAU interrupts

There are two types of interrupt registers in CAU, which are CAU_STAT1 and CAU_INTF. In CAU, the interrupt is used to indicate the situation of the input and output FIFO.

Any of input and output FIFO interrupt can be enabled or disabled by configuring the Interrupt Enable register CAU_INTEN. Value 1 of the register enable the interrupts.

Input FIFO interrupt

The input FIFO interrupt is asserted when the number of words in the input FIFO is less than four words, then ISTA is asserted. And if the input FIFO interrupt is enabled by IINTEN with a 0 value, the IINTF is also asserted. Note if the CAUEN is low, then the ISTA and IINTF are also always low.

Output FIFO interrupt

The output FIFO interrupt is asserted when the number of words in the output FIFO is more than one words, then OSTA is asserted. And if the output FIFO interrupt is enabled by OINTEN with a 0 value, the OINTF is also asserted. Note Unlike that of Input FIFO interrupt, the value of CAUEN will never affect the situation of OSTA and OINTF.

10.8. CAU suspended mode

It is possible to suspend a data block if another new data block with a higher priority needs to be processed in CAU. The following steps can be performed to complete the encryption/decryption acceleration of the suspended data blocks.

When DMA transfer is used:

1. Stop the current input transfer. Clear the DMAIEN bit in the CAU_DMAEN register.
2. When it is DES or AES, wait until both the input and output FIFO are both empty and BUSY bit is cleared, so that the next data block will not be affected by the last one. Case of TDES is similar to that of AES except that it does not need to wait until the input FIFO is empty.
3. Stop the output transfer by clearing the DMAOEN bit in the CAU_DMAEN register. And disable the CAU by clearing the CAUEN bit in the CAU_CTL register.
4. Save the configuration, including the key size, data type, operation mode, direction and the key values. When it is CBC or CTR chaining mode, the initialization vectors should also be stored.
5. Configure and process the new data block.
6. Restore the process before. Configure the CAU with the parameters stored before, and

prepare the key and initialization vectors. Then enable CAU by setting the CAUEN bit in the CAU_CTL register

When data transfer is done by CPU access to CAU_DI and CAU_DO:

1. When the data transfer is done by CPU access, then wait for the fourth read of the CAU_DO register and before the next CAU_DI write access so that the message is suspended at the end of a block processing.
2. Disable the CAU by clearing the CAUEN bit in the CAU_CTL register.
3. Save the configuration, including the key size, data type, operation mode, direction and the key values. When it is CBC or CTR chaining mode, the initialization vectors should also be stored.
4. Configure and process the new data block.
5. Restore the process before. Configure the CAU with the parameters stored before, and prepare the key and initialization vectors. Then enable CAU by setting the CAUEN bit in the CAU_CTL register

10.9. Register definition

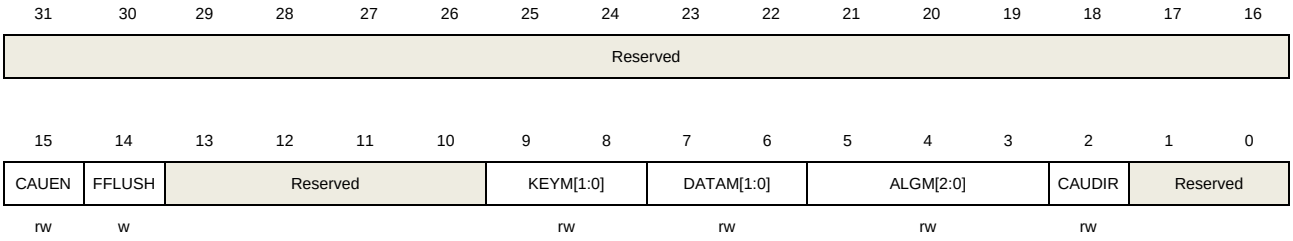
CAU start address: 0x5006 0000

10.9.1. CAU control register (CAU_CTL)

Address offset: 0x00

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



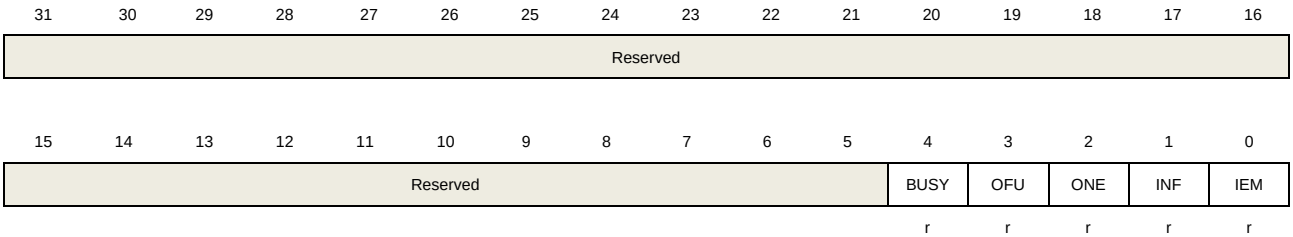
Bits	Fields	Descriptions
31:16	Reserved	Must keep the reset value
15	CAUEN	CAU Enable 0: CAU is disabled 1: CAU is enabled Note the CAUEN can be cleared automatically when the key derivation (ALGM=111b) is finished
14	FFLUSH	Flush FIFO 0: No effect 1: When CAUEN=1, flush the input and output FIFO Reading this bit always returns 0
13:10	Reserved	Must keep the reset value
9:8	KEYM[1:0]	AES key size mode configuration, must be configured when BUSY=0 00: 128-bit key length 01: 192-bit key length 10: 256-bit key length 11: never use
7:6	DATAM[1:0]	Data swapping type mode configuration, must be configured when BUSY=0 00: No swapping 01: Half-word swapping 10: Byte swapping 11: Bit swapping

5:3	ALGM[2:0]	Encryption/decryption algorithm mode, must be configured when BUSY=0 000: TDES-ECB with CAU_KEY1, 2, 3. Initialization vectors (CAU_IV0..1) are not used 001: TDES-CBC with CAU_KEY1, 2, 3. Initialization vectors (CAU_IV0) is used to XOR with data blocks 010: DES-ECB with only CAU_KEY1 Initialization vectors (CAU_IV0..1) are not used 011: DES-CBC with only CAU_KEY1 Initialization vectors (CAU_IV0) is used to XOR with data blocks 100: AES-ECB with CAU_KEY0, 1, 2, 3. Initialization vectors (CAU_IV0..1) are not used 101: AES-CBC with CAU_KEY0, 1, 2, 3. Initialization vectors (CAU_IV0..1) are used to XOR with data blocks 110: AES_CTR with CAU_KEY0, 1, 2, 3. Initialization vectors (CAU_IV0..1) are used to XOR with data blocks In this mode, encryption and decryption are same, then the CAUDIR is disregarded. 111: AES key derivation for decryption mode. The input key must be same to that used in encryption. The BUSY bit is set until the process has been finished, and CAUEN is then cleared.
2	CAUDIR	CAU direction, must be configured when BUSY=0 0: encryption 1: decryption
1:0	Reserved	Must keep the reset value

10.9.2. CAU Status register 0 (CAU_STAT0)

Address offset: 0x04
Reset value: 0x0000 0003

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:5	Reserved	Must keep the reset value
4	BUSY	Busy bit

		0: No processing. This is because: - CAU is disabled by CAUEN=0 or the processing has been completed. - No enough data or no enough space in the input/output FIFO to perform a data block 1: CAU is processing data or key derivation.
3	OFU	Output FIFO is full 0: Output FIFO is not full 1: Output FIFO is full
2	ONE	Output FIFO is not empty 0: Output FIFO is empty 1: Output FIFO is not empty
1	INF	Input FIFO is not full 0: Input FIFO is full 1: Input FIFO is not full
0	IEM	Input FIFO is empty 0: Input FIFO is not empty 1: Input FIFO is empty

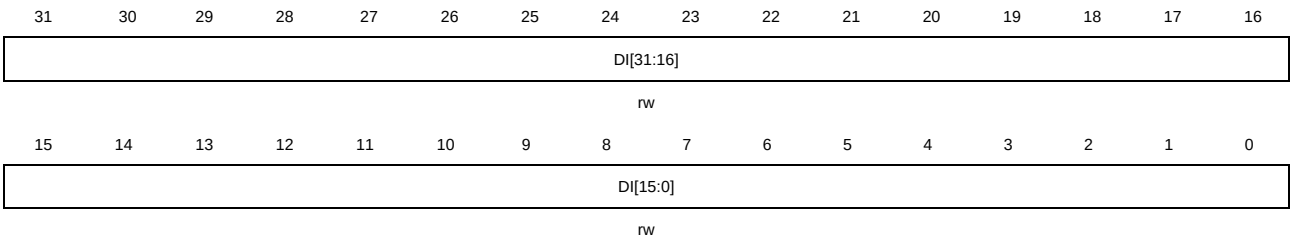
10.9.3. CAU data input register (CAU_DI)

Address offset: 0x08

Reset value: 0x0000 0000

The data input register is used to transfer plaintext or ciphertext blocks into the input FIFO for processing. The MSB is firstly written into the FIFO and the LSB is the last one. If the CAUEN is 0 and the input FIFO is not empty, when it is read, then the first data in the FIFO is popped out and returned. If the CAUEN is 1, the returned value is undefined. Once it is read, then the FIFO must be flushed.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:0	DI[31:0]	Data input Write these bits will write data to IN FIFO, read these bits will return IN FIFO value if CAUEN is 0, or it will return an undefined value

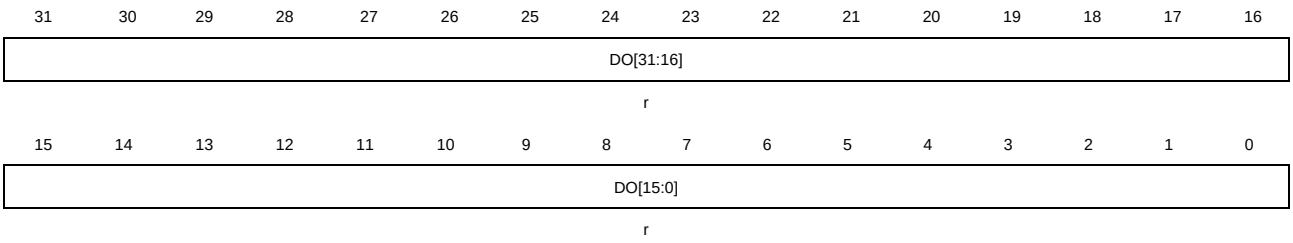
10.9.4. CAU data output register (CAU_DO)

Address offset: 0x0C

Reset value: 0x0000 0000

The data output register is a read only register. It is used to receive plaintext or ciphertext results from the output FIFO. Similar to CAU_DI, the MSB is read at first while the LSB is read at last.

This register has to be accessed by word (32-bit)



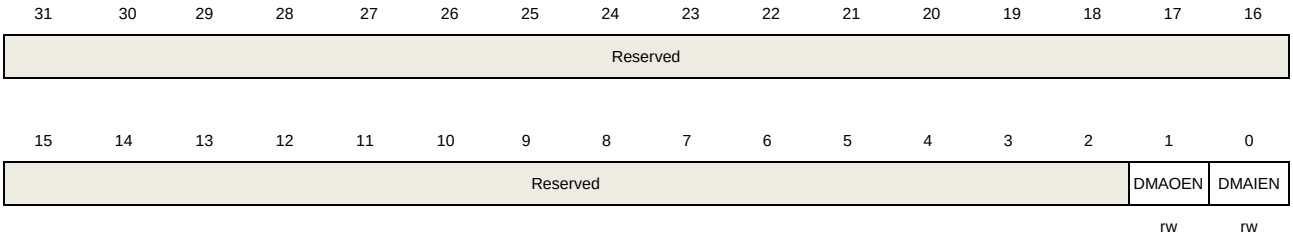
Bits	Fields	Descriptions
31:0	DO[31:0]	Data output These bits are read only, read these bits return OUT FIFO value.

10.9.5. CAU DMA enable register (CAU_DMAEN)

Address offset: 0x10

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:2	Reserved	Must keep the reset value
1	DMAOEN	DMA output enable 0: DMA for OUT FIFO data is disabled 1: DMA for OUT FIFO data is enabled
0	DMAIEN	DMA input enable 0: DMA for IN FIFO data is disabled

1: DMA for IN FIFO data is enabled

10.9.6. CAU interrupt enable register (CAU_INTEN)

Address offset: 0x14

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														OINTEN	IINTEN
														rw	rw

Bits	Fields	Descriptions
31:2	Reserved	Must keep the reset value
1	OINTEN	OUT FIFO interrupt enable 0: OUT FIFO interrupt is disable 1: OUT FIFO interrupt is enable
0	IINTEN	IN FIFO interrupt enable 0: IN FIFO interrupt is disable 1: IN FIFO interrupt is enable

10.9.7. CAU Status register 1 (CAU_STAT1)

Address offset: 0x18

Reset value: 0x0000 0001

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														OSTA	ISTA
														r	r

Bits	Fields	Descriptions
31:2	Reserved	Must keep the reset value
1	OSTA	OUT FIFO interrupt status

		0: OUT FIFO interrupt status not pending 1: OUT FIFO interrupt status pending
0	ISTA	IN FIFO interrupt status 0: IN FIFO interrupt not pending 1: IN FIFO interrupt flag pending

10.9.8. CAU interrupt flag register (CAU_INTF)

Address offset: 0x1C
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														OINTF	IINTF
														r	r

Bits	Fields	Descriptions
31:2	Reserved	Must keep the reset value
1	OINTF	OUT FIFO enabled interrupt flag 0: OUT FIFO Interrupt not pending 1: OUT FIFO Interrupt pending
0	IINTF	IN FIFO enabled interrupt flag 0: IN FIFO Interrupt not pending 1: IN FIFO Interrupt pending when CAUEN is 1

10.9.9. CAU key registers (CAU_KEY0..3(H/L))

Address offset: 0x20 to 0x3C
Reset value: 0x0000 0000

This registers have to be accessed by word (32-bit), and all of them must be written when BUSY is 0.

In DES mode, only CAU_KEY1 is used.

In TDES mode, CAU_KEY1, CAU_KEY2 and CAU_KEY3 are used.

In AES-128 mode, KEY2H[31:0] || KEY2L[31:0] is used as AES_KEY[0:63], and KEY3H[31:0] || KEY3L[31:0] is used as AES_KEY[64:127].

In AES-192 mode, KEY1H[31:0] || KEY1L[31:0] is used as AES_KEY[0:63], KEY2H[31:0] ||

KEY2L[31:0] is used as AES_KEY[64:127], and KEY3H[31:0] || KEY3L[31:0] is used as AES_KEY[128:191].

In AES-256 mode, KEY0H[31:0] || KEY0L[31:0] is used as AES_KEY[0:63], KEY1H[31:0] || KEY1L[31:0] is used as AES_KEY[64:127], KEY2H[31:0] || KEY2L[31:0] is used as AES_KEY[128:191], and KEY3H[31:0] || KEY3L[31:0] is used as AES_KEY[192:255].

NOTE: "||" is a concatenation operator. For example, X || Y denotes the concatenation of two bit strings X and Y.

10.9.10. CAU Initial vector registers (CAU_IV0..1(H/L))

Address offset: 0x40 to 0x4C
Reset value: 0x0000 0000

This registers have to be accessed by word (32-bit), and all of them must be written when BUSY is 0.

In DES/TDES mode, IV0H is the leftmost bits, and IV0L is the rightmost bits of the initialization vectors.

In AES mode, IV0H is the leftmost bits, and IV1L is the rightmost bits of the initialization vectors.

Bits	Fields	Descriptions
31:0	IV0...1(H/L)	The initialization vector for DES, TDES, AES

11. Hash Acceleration Unit (HAU)

11.1. Overview

The hash acceleration unit is used for information security. The secure hash algorithm (SHA-1, SHA-224, SHA-256), the message-digest algorithm (MD5) and the keyed-hash message authentication code (HMAC) algorithm are supported for various applications. The digest will be computed and the length is 160/224/256/128 bits for a message up to (264 - 1) bits computed by SHA-1, SHA-224, SHA-256 and MD5 algorithms respectively. In HMAC algorithm, SHA-1, SHA-224, SHA-256 or MD5 will be called twice as hash functions and authenticating messages can be produced.

The HAU is fully compliant implementation of the following standards:

- Federal Information Processing Standards Publication 180-2 (FIPS PUB 180-2)
- Secure Hash Standard specifications (SHA-1, SHA-224, SHA-256)
- Internet Engineering Task Force Request for Comments number 1321 (IETF RFC 1321) specifications (MD5)

11.2. Characteristics

- 32-bit AHB slave peripheral
- High performance of computation of hash algorithms
- Little-endian data representation
- Multiple data types are supported, including no swapping, half-word swapping, byte swapping, and bit swapping with 32-bit data words
- Automatic data padding to fill the 512-bit message block for digest computation
- DMA transfer is supported

11.3. HAU data type

The hash acceleration unit receives data words of 32 bits at a time, while they are processed in 512-bits blocks. For each input word, according to the data type, the data could be bit/byte/half-word/no swapped before they are transferred into the hash acceleration core. The same swapping operation should be also performed on the core output data before they are collected. Note the least-significant data always occupies the lowest address location no matter which data type is configured, because the system memory is little-endian. However, the computation of SHA-1, SHA-224 and SHA-256 are big-endian.

Figure 11-1. DATAM No swapping and Half-word swapping and *Figure 11-2. DATAM Byte swapping and Bit swapping* illustrate the data swapping according to different data types.

Figure 11-1. DATAM No swapping and Half-word swapping

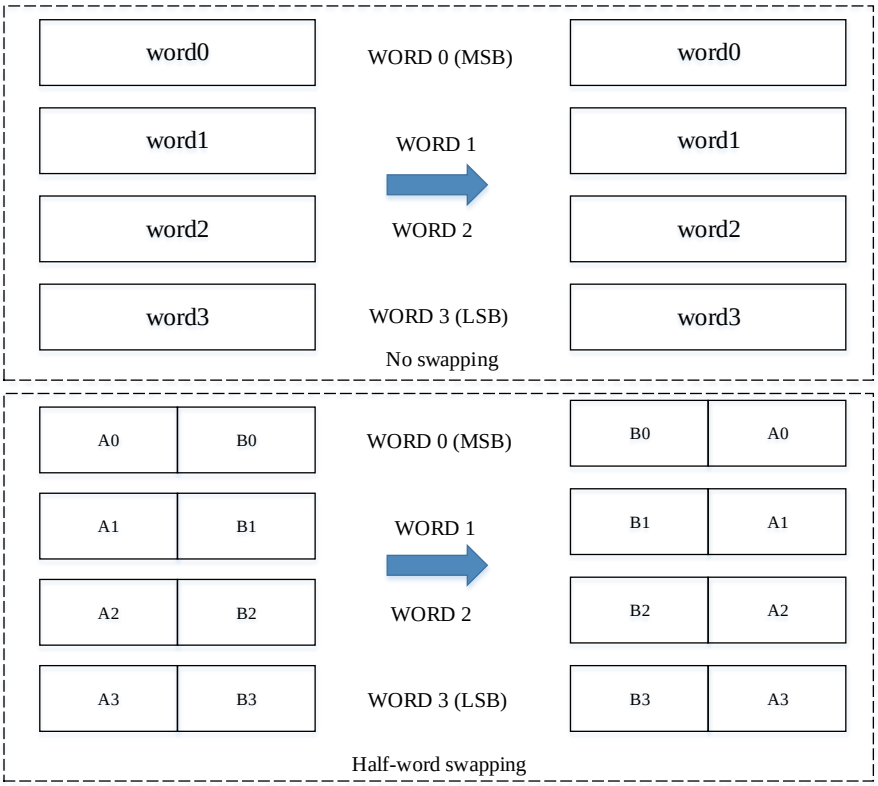

Figure 11-2. DATAM Byte swapping and Bit swapping

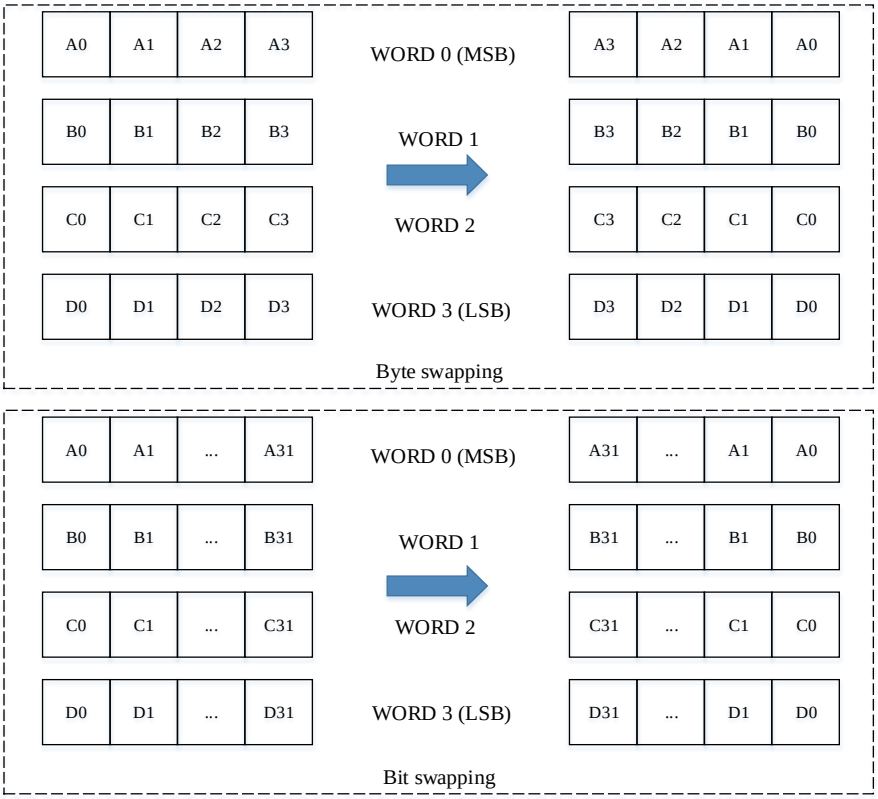
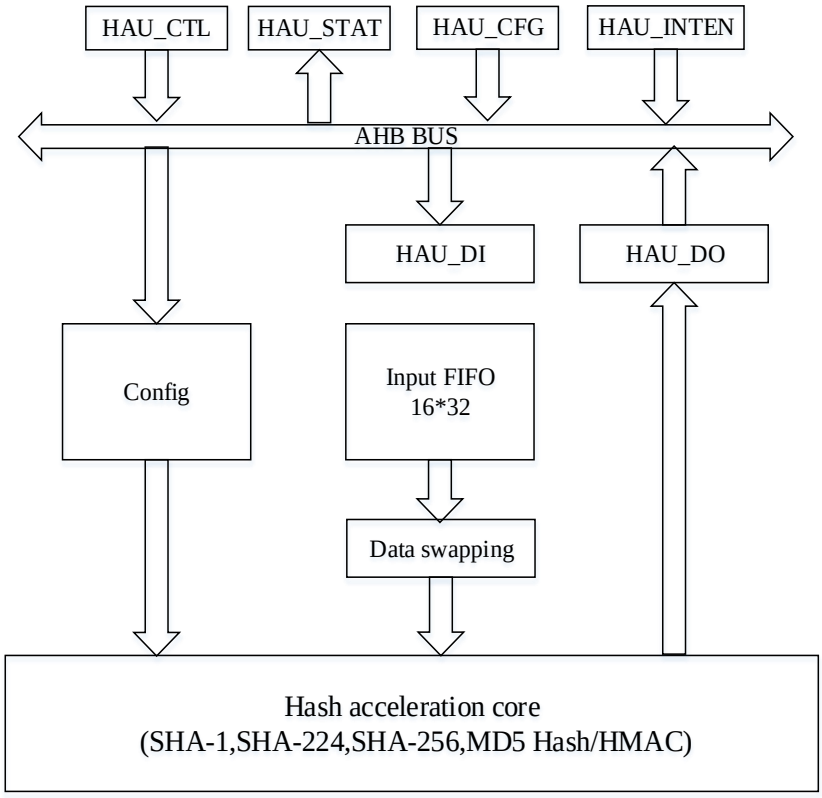


11.4. HAU core

The hash acceleration unit is used to compute condensed information of input messages with secure hash algorithms. The digest result has a length of 160/224/256/128 bits for a message up to (264-1) bits computed by SHA-1, SHA-224, SHA256 and MD5 algorithms respectively. It can be used to generate or verify the signature of a message with a higher efficiency because of the much simpler of the information.

A message which need to be processed in the HAU should be considered as bit information. And the length is the number of bits of the message. The information security is ensured because that, to find the original message using the digest is computationally impossible and, the result will be completely different with any change to the input message.

Figure 11-3. HAU block diagram



11.4.1. Automatic data padding

The input message should be padded first so that the number of bits in the input of the HAU core can be an integral multiple of 512. First of all, a “1” is added to follow the last bit of the input message, and then several “0” should be padded to ensure the result modulo 512 is 448, at last, a 64-bit length information of input is added.

After the message padding is correctly performed, the VBL bits in the HAU_CFG register is configured as the 64-bit length value above, and CALEN bit in the HAU_CFG register can be set 1 to start the calculation of the digest of the last block.

Data Padding Example: The input message is “HAU”, which ASCII hexadecimal code is:

484155

Then the VBL bits in the HAU_CFG register is set as decimal 24 because of the valid bit length. A “1” is added at bit location 24 then, and several “0” are padded so that the result modulo 512 is 448, the hexadecimal result is as follows:

48415580 00000000 00000000 00000000

00000000 00000000 00000000 00000000

00000000 00000000 00000000 00000000

00000000 00000000

After that, a 64-bit length information of the input message is padded, which hexadecimal value is 18, and the final result will be:

48415580 00000000 00000000 00000000

00000000 00000000 00000000 00000000

00000000 00000000 00000000 00000000

00000000 00000000 00000000 00000018

11.4.2. Digest computing

After data padding, for each block calculation of HAU, 512 bits are written into the HAU core by DMA or CPU. To start the processing of the HAU core, the peripheral must obtain the information as to whether the HAU_DI register contains the last bits of the message or not. This can be confirmed with the status of the input FIFO and the HAU_DI register.

When DMA is used to transfer data:

The status of the block transfer is automatically interpreted with the information from the DMA controller. And padding and digest computation are performed automatically as if CALEN bit in the HAU_CFG register is set as 1.

Note: If hash message is large files and multiple DMA transfers are needed, then MDS bit should be set as 1. And the VBL bits need to be set before the transfer. The CALEN bit is not set automatically after an intermediate DMA transfer completed. Only when the last DMA transfer is processing, the MDS bit is cleared so that the CALEN bit is automatically set after data transferring.

Otherwise, the MDS bit is set as 0. And the CALEN bit is set automatically after a DMA transfer. Also, VBL bits need to set before the DMA transfer.

When CPU is used to transfer data without DMA:

- The intermediate block computing can be started when HAU_DI is filled with another new word of the next block
- The last block computing can be started when CALEN bit in the HAU_CFG register is 1.

11.4.3. Hash mode

The hash mode is selected when the HMS bit in the HAU_CTL register is set as 0. And when the START bit in the HAU_CTL register is 1, SHA-1, SHA-224, SHA-256 and MD5 mode computation is chosen by the ALGM bits.

After a message block of 512 bit has been received through the HAU_DI register and the input FIFO, the processor starts the calculation with the information from DMA or the status of the CALEN bit.

The results can be finally read from the HAU_DO0..7 registers.

11.4.4. HMAC mode

HMAC mode is used for message authentication with a unique key chosen by the user. More information about the HMAC specifications please refer to “HMAC: keyed-hashing for message authentication, H. Krawczyk, M. Bellare, R. Canetti, February 1997”.

The HMAC algorithm can be represented as:

HMAC(input) = HASH[((key | opad) XOR 0x5c) | HASH(((key | ipad) XOR 0x36) | input)]

where ipad and opad are used to extend the key to 512 bits with several “0” and | is the concatenation operator.

There are four different phases in the HMAC mode:

1. Configure the HMS bit in the HAU_CTL register as 1 and set the ALGM bits as the desired algorithm. If the key size is longer than 64 bytes, then the KLM bit in the HAU_CTL register should also be set. After that, start the HAU core by set the START bit.
2. The key is used as the input message to complete the calculation in HASH mode.
3. The new key is elaborated when the last word is accessed and computation has started.
4. After the first hash round, the new key can be used for the outer hash function. And when the last word of the key is entered and computation starts, the results are available in the HAU_DO registers.

11.5. HAU interrupt

There are two types of interrupt registers in HAU, which are both in HAU_STAT register. In HAU, the interrupt is used to indicate the situation of the input FIFO and the status of whether the digest calculation is completed.

Any of interrupts can be enabled or disabled by configuring the HAU interrupt enable register HAU_INTEN. Value 1 of the register enable the interrupts.

Input FIFO interrupt

The input FIFO interrupt is asserted when there is enough space in the input FIFO, then DINT is asserted. Note if the input FIFO interrupt is disenabled by DIIE with a 0 value, the DINT is always de-asserted.

Calculation completion interrupt

The calculation completion interrupt is asserted when the digest calculation is finished, then

CINT is asserted. Note if the calculation completion interrupt is disenabled by CCIE with a 0 value, the CINT is always de-asserted.

11.6. Register definition

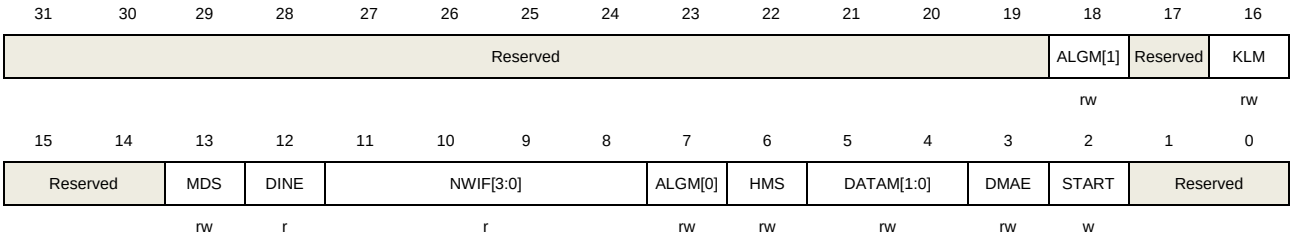
HAU start address: 0x5006 0400

11.6.1. HAU control register (HAU_CTL)

Address offset: 0x00

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:19	Reserved	Must keep the reset value
18	ALGM[1]	Algorithm selection bit 1
17	Reserved	Must keep the reset value
16	KLM	Key length mode 0: Key length ≤ 64 bytes 1: Key length > 64 bytes Note this bit must be changed when no computation is processing
15:14	Reserved	Must keep the reset value
13	MDS	Multiple DMA Selection Set this bit if hash message is large files and multiple DMA transfers are needed. 0: Single DMA transfers needed and CALEN bit is automatically set at the end of a DMA transfer. 1: Multiple DMA transfers needed and CALEN bit is not automatically set at the end of a DMA transfer.
12	DINE	DI register not empty 0: The input FIFO is empty 1: The input FIFO is not empty Note this bit is cleared when START bit or CALEN bit is set as 1
11:8	NWIF[3:0]	Number of words in the input FIFO Note these bits is cleared when START bit set or a digest calculation starts (CALEN

		bit is set as 1, or DMA end of transfer)
7	ALGM[0]	Algorithm selection bit 0 This bit and bit 18 of CTL are written by software to select the SHA-1, SHA-224, SHA256 or the MD5 algorithm: 00: Select SHA-1 algorithm 01: Select MD5 algorithm 10: Select SHA224 algorithm 11: Select SHA256 algorithm
6	HMS	HAU mode selection, must be changed when no computation is processing 0: HASH mode selected 1: HMAC mode selected. If the key length is longer than 64 bytes, then KLM bit must also be set
5:4	DATAM[1:0]	Data type mode Defines the format of the data entered into the HAU_DI register: 00: no swapping. The data written to HAU_DI is direct write to FIFO without swapping. 01: half-word swapping. The data written into HAU_DI need half-word swapping before write to FIFO. 10: bytes swapping. The data written into HAU_DI need bytes swapping before write to FIFO. 11: bit swapping. The data written into HAU_DI need bytes swapping before write to FIFO.
3	DMAE	DMA enable 0: DMA disabled 1: DMA enabled Note 1. this bit is cleared when transferring the last data of the message, but not cleared because of START 2. When DMA is transferring, writing 0 to this bit will not stop the current transfer until the transfer is completed or START is set as 1
2	START	Start the digest calculation 1: Start the digest of a new message 0: No effect Note: reading this bit always returns 0
1:0	Reserved	Must keep the reset value

11.6.2. HAU data input register (HAU_DI)

Address offset: 0x04
Reset value: 0x0000 0000

The data input register is used to transfer message with 512-bit blocks into the input FIFO for

processing. Any new write operation to this register will be extended while the digest calculation is in process until it has been finished.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31:0	DI[31:0]	Message data input When write to these registers, the current content pushed to IN FIFO and new value updates. When read, returns the current content.

11.6.3. HAU configuration register (HAU_CFG)

Address offset: 0x08

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CALEN	Reserved			VBL[4:0]				
							w				rw				

Bits	Fields	Descriptions
31:9	Reserved	Must keep the reset value
8	CALEN	Digest calculation enable 0: No calculation 1: Start data padding with VBL prepared previously. Start the calculation of the last digest Note: reading this bit always returns 0
7:5	Reserved	Must keep the reset value
4:0	VBL[4:0]	Valid bits length in the last word 0x00: All 32 bits of the last data written to HAU_DI after data swapping are valid. 0x01: Only bit [31] of the last data written to HAU_DI after data swapping are valid. 0x02: Only bits [31:30] of the last data written to HAU_DI after data swapping are

valid.

0x03: Only bits [31:29] of the last data written to HAU_DI after data swapping are valid.

...

0x1F: Only bits [0] of the last data written to HAU_DI after data swapping are valid.

Note: this bits must be configured before setting the CALEN bit.

11.6.4. HAU data output register (HAU_DO0..7)

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

The data output registers are read only registers. They are used to receive results from the output FIFO. And they are reset by the START bit. Any read access when calculating will be extended until the calculation is completed.

In SHA-1 mode, HAU_DO0…4 are used

In MD5 mode, HAU_DO0…3 are used

In SHA-224 mode, HAU_DO0…6 are used

In SHA-256 mode, HAU_DO0…7 are used

12. Direct memory access controller (DMA)

12.1. Overview

The direct memory access (DMA) controller provides a hardware method of transferring data between peripherals and/or memory without intervention from the CPU, thereby freeing up bandwidth for other system functions. Data can be quickly moved by DMA between peripherals and memory as well as memory and memory without any CPU actions. There are 14 channels in the DMA controller (7 for DMA0 and 7 for DMA1). Each channel is dedicated to manage memory access requests from one or more peripherals. An arbiter is implemented inside to handle the priority among DMA requests.

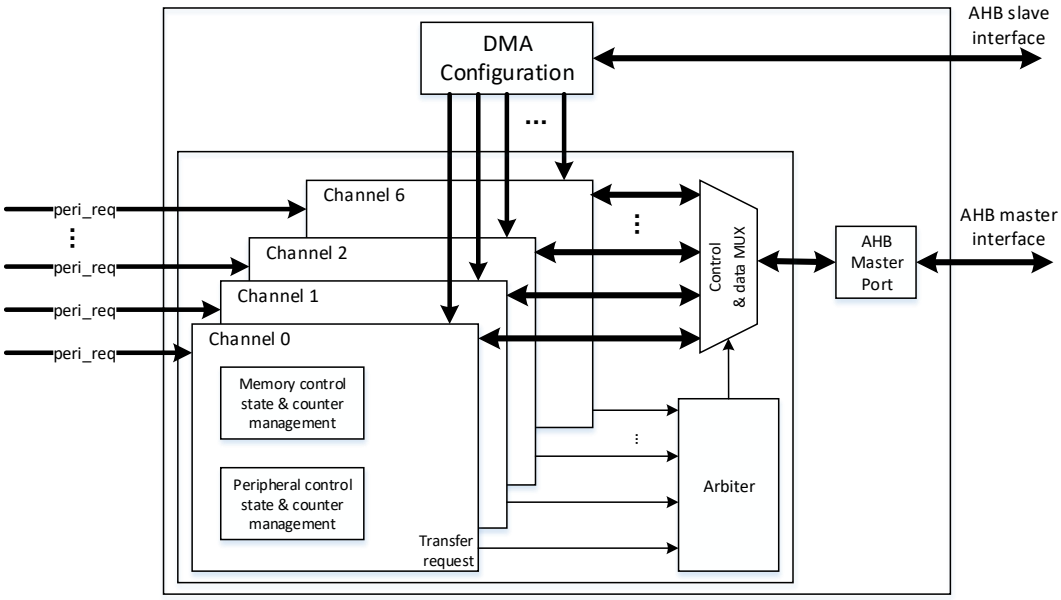
The system bus is shared by the DMA controller and the Cortex™-M3 core. When the DMA and the CPU are targeting the same destination, the DMA access may stop the CPU access to the system bus for some bus cycles. Round-robin scheduling is implemented in the bus matrix to ensure at least half of the system bus bandwidth for the CPU.

12.2. Characteristics

- Programmable length of data to be transferred, max to 65536.
- 14 channels and each channel are configurable (7 for DMA0 and 7 for DMA1).
- AHB and APB peripherals, FLASH, SRAM can be accessed as source and destination.
- Each channel is connected to fixed hardware DMA request.
- Software DMA channel priority (low, medium, high, ultra high) and hardware DMA channel priority (DMA channel 0 has the highest priority and DMA channel 6 has the lowest priority).
- Support independent 8, 16, 32-bit memory and peripheral transfer.
- Support independent fixed and increasing address generation algorithm of memory and peripheral.
- Support circular transfer mode.
- Support peripheral to memory, memory to peripheral, and memory to memory transfers.
- One separate interrupt per channel with three types of event flags.Support interrupt enable and clear.
- Support Full_Data transfer mode: when the transfer size of source and destination are not equal and the transfer size of source is 32-bit, the DMA automatically unpacks the necessary transfers to optimize the destination transfer size. This feature is only available for the channel 5 of DMA1.

12.3. Block diagram

Figure 12-1. Block diagram of DMA



As shown in ***Figure 12-1. Block diagram of DMA***, a DMA controller consists of four main parts:

- DMA configuration through AHB slave interface
- Data transmission through two AHB master interfaces for memory access and peripheral access
- An arbiter inside to manage multiple peripheral requests coming at the same time
- Channel management to control address/data selection and data counting

12.4. Function overview

12.4.1. DMA operation

Each DMA transfer consists of two operations, including the loading of data from the source and the storage of the loaded data to the destination. The source and destination addresses are computed by the DMA controller based on the programmed values in the DMA_CHxPADDR, DMA_CHxMADDR, and DMA_CHxCTL registers. The DMA_CHxCNT register controls how many transfers to be transmitted on the channel. The PWIDTH and MWIDTH bits in the DMA_CHxCTL register determine how many bytes to be transmitted in a transfer. Normal transfer mode or Full_Data transfer mode can be set using the FD_CH5EN bit in the DMA_ACFG register.

The CNT bits in the DMA_CHxCNT register control how many data to be transmitted on the

channel and must be configured before enable the CHEN bit in the register. During the transmission, the CNT bits indicate the remaining number of data items to be transferred.

The DMA transmission is disabled by clearing the CHEN bit in the DMA_CHxCTL register.

- If the DMA transmission is not completed when the CHEN bit is cleared, two situations may be occurred when restart this DMA channel:
  - If no register configuration operations of the channel occurs before restart the DMA channel, the DMA will continue to complete the rest of the transmission.
  - If any register configuration operations occur, the DMA will restart a new transmission.
- If the DMA transmission has been finished when clearing the CHEN bit, enable the DMA channel without any register configuration operation will not launch any DMA transfer.

Normal Mode

Suppose DMA_CHxCNT is 4, and both PNAGA and MNAGA are set. The DMA transfer operations for each combination of PWIDTH and MWIDTH are shown in the following table.

Table 12-1. DMA transfer operations (Normal Mode)

Transfer size		Transfer operations	
Source	Destination	Source	Destination
32 bits	32 bits	1: Read B3B2B1B0[31:0] @0x0 2: Read B7B6B5B4[31:0] @0x4 3: Read BBBAB9B8[31:0] @0x8 4: Read BFBEBDBC[31:0] @0xC	1: Write B3B2B1B0[31:0] @0x0 2: Write B7B6B5B4[31:0] @0x4 3: Write BBBAB9B8[31:0] @0x8 4: Write BFBEBDBC[31:0] @0xC
32 bits	16 bits	1: Read B3B2B1B0[31:0] @0x0 2: Read B7B6B5B4[31:0] @0x4 3: Read BBBAB9B8[31:0] @0x8 4: Read BFBEBDBC[31:0] @0xC	1: Write B1B0[7:0] @0x0 2: Write B5B4[7:0] @0x2 3: Write B9B8[7:0] @0x4 4: Write BDBC[7:0] @0x6

8 bits	8 bits	1: Read B0[7:0] @0x0 2: Read B1[7:0] @0x1 3: Read B2[7:0] @0x2 4: Read B3[7:0] @0x3	1, Write B0[7:0] @0x0 2, Write B1[7:0] @0x1 3, Write B2[7:0] @0x2 4, Write B3[7:0] @0x3

Full_Data Mode

In Full_Data mode, the transfer size of source and destination must not be equal and the transfer size of source must be 32-bit. If the transfer size of destination is 16-bit, each DMA transfer is achieved with one source operation followed by two destination operations. If the transfer size of destination is 8-bit, four destination operations are needed to complete one DMA transfer. Suppose DMA_CHxCNT is 2, and both PNAGA and MNAGA are set. The DMA transfer operations for each combination of PWIDTH and MWIDTH are shown in the following table.

Table 12-2. DMA transfer operations (Full_Data Mode)

Transfer size		Transfer operations	
Source	Destination	Source	Destination
32 bits	16 bits	1: Read B3B2B1B0[31:0] @0x0	1: Write B1B0[16:0] @0x0 2: Write B3B2[16:0] @0x2
		2: Read B7B6B5B4[31:0] @0x4	1: Write B5B4[16:0] @0x4 2: Write B7B6[16:0] @0x6
32 bits	8 bits	1: Read B3B2B1B0[31:0] @0x0	1: Write B0[7:0] @0x0 2: Write B1[7:0] @0x1 3: Write B2[7:0] @0x2 4: Write B3[7:0] @0x3
		2: Read B7B6B5B4[31:0] @0x4	1: Write B4[7:0] @0x4 2: Wirte B5[7:0] @0x5 3: Write B6[7:0] @0x6 4: Write B7[7:0] @0x7

NOTE: The Full_Data transfer mode is only available for the channel 5 of DMA1.

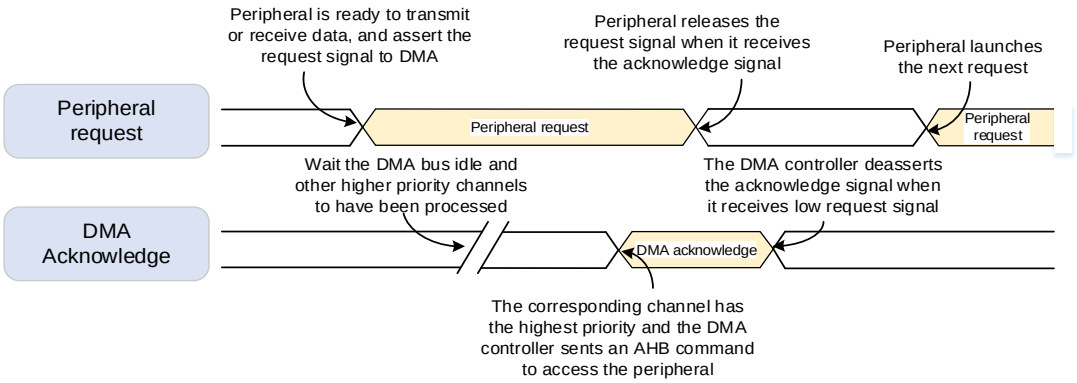
12.4.2. Peripheral handshake

To ensure a well-organized and efficient data transfer, a handshake mechanism is introduced between the DMA and peripherals, including a request signal and a acknowledge signal:

- Request signal asserted by peripheral to DMA controller, indicating that the peripheral is ready to transmit or receive data
- Acknowledge signal responded by DMA to peripheral, indicating that the DMA controller has initiated an AHB command to access the peripheral

Figure 12-2. Handshake mechanism shows how the handshake mechanism works between the DMA controller and peripherals.

Figure 12-2. Handshake mechanism



12.4.3. Arbitration

When two or more requests are received at the same time, the arbiter determines which request is served based on the priorities of channels. There are two-stage priorities, including the software priority and the hardware priority. The arbiter determines which channel is selected to respond according to the following priority rules:

- Software priority: Four levels, including low, medium, high and ultra high by configuring the PRIO bits in the DMA_CHxCTL register.
- For channels with equal software priority level, priority is given to the channel with lower channel number.

12.4.4. Address generation

Two kinds of address generation algorithm are implemented independently for memory and peripheral, including the fixed mode and the increased mode. The PNAGA and MNAGA bit in the DMA_CHxCTL register are used to configure the next address generation algorithm of peripheral and memory.

In the fixed mode, the next address is always equal to the base address configured in the base address registers (DMA_CHxPADDR, DMA_CHxMADDR).

In the increasing mode, the next address is equal to the current address plus 1 or 2 or 4, depending on the transfer data width.

12.4.5. Circular mode

Circular mode is implemented to handle continue peripheral requests (for example, ADC scan mode). The circular mode is enabled by setting the CMEN bit in the DMA_CHxCTL register.

In circular mode, the CNT bits are automatically reloaded with the pre-programmed value and the full transfer finish flag is asserted at the end of every DMA transfer. DMA can always responds the peripheral request until the CHEN bit in the DMA_CHxCTL register is cleared.

12.4.6. Memory to memory mode

The memory to memory mode is enabled by setting the M2M bit in the DMA_CHxCTL register. In this mode, the DMA channel can also work without being triggered by a request from a peripheral. The DMA channel starts transferring as soon as it is enabled by setting the CHEN bit in the DMA_CHxCTL register, and completed when the DMA_CHxCNT register reaches zero.

12.4.7. Channel configuration

When starting a new DMA transfer, it is recommended to respect the following steps:

1. Read the CHEN bit and judge whether the channel is enabled or not. If the channel is enabled, clear the CHEN bit by software. When the CHEN bit is read as ‘0’, configuring and starting a new DMA transfer is allowed.
2. Configure the M2M bit and DIR bit in the DMA_CHxCTL register to set the transfer mode.
3. Configure the CMEN bit in the DMA_CHxCTL register to enable/disable the circular mode.

4. Configure the PRIO bits in the DMA_CHxCTL register to set the channel software priority.
5. Configure the memory and peripheral transfer width, memory and peripheral address generation algorithm in the DMA_CHxCTL register.
6. Configure the enable bit for full transfer finish interrupt, half transfer finish interrupt, transfer error interrupt in the DMA_CHxCTL register.
7. Configure the DMA_CHxPADDR register for setting the peripheral base address.
8. Configure the DMA_CHxMADDR register for setting the memory base address.
9. Configure the DMA_CHxCNT register to set the total transfer data number.
10. Configure the DMA_ACFG register for setting the transfer mode for channel 5 of DMA1 if needed.
11. Configure the CHEN bit with '1' in the DMA_CHxCTL register to enable the channel.

12.4.8. Interrupt

Each DMA channel has a dedicated interrupt. There are three types of interrupt event, including full transfer finish, half transfer finish, and transfer error.

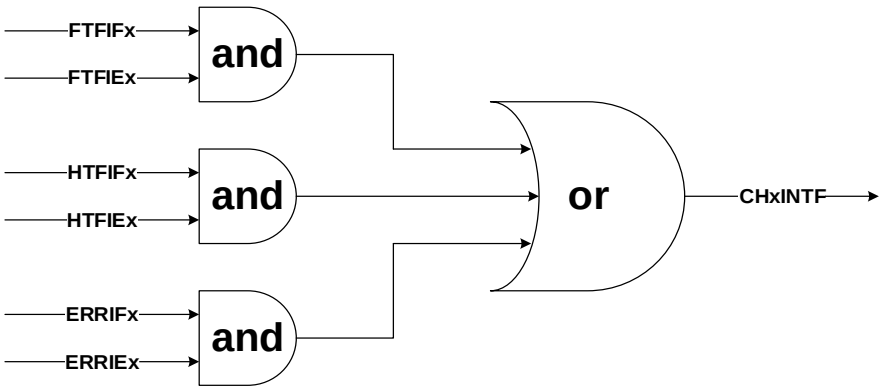
Each interrupt event has a dedicated flag bit in the DMA_INTF register, a dedicated clear bit in the DMA_INTC register, and a dedicated enable bit in the DMA_CHxCTL register. The relationship is described in the following ***Table 12-3. Interrupt events***.

Table 12-3. Interrupt events

Interrupt event	Flag bit	Clear bit	Enable bit
	DMA_INTF	DMA_INTC	DMA_CHxCTL
Full transfer finish	FTFIF	FTFIFC	FTFIE
Half transfer finish	HTFIF	HTFIFC	HTFIE
Transfer error	ERRIF	ERRIFC	ERRIE

The DMA interrupt logic is shown in the ***Figure 12-3. DMA interrupt logic***, an interrupt can be produced when any type of interrupt event occurs and enabled on the channel.

Figure 12-3. DMA interrupt logic



Note: "x" indicates channel number (x=0…6).

12.4.9. DMA request mapping

Several requests from peripherals may be mapped to one DMA channel. They are logically ORed before entering the DMA. For details, see the following ***Figure 12-4. DMA0 request mapping*** and ***Figure 12-5. DMA1 request mapping***. The request of each peripheral can be independently enabled or disabled by programming the registers of the corresponding peripheral. The user has to ensure that only one request is enabled at a time on one channel. ***Table 12-4. DMA0 requests for each channel*** lists the support request from peripheral for each channel of DMA0, and ***Table 12-5. DMA1 requests for each channel*** lists the support request from peripheral for each channel of DMA1.

Figure 12-4. DMA0 request mapping

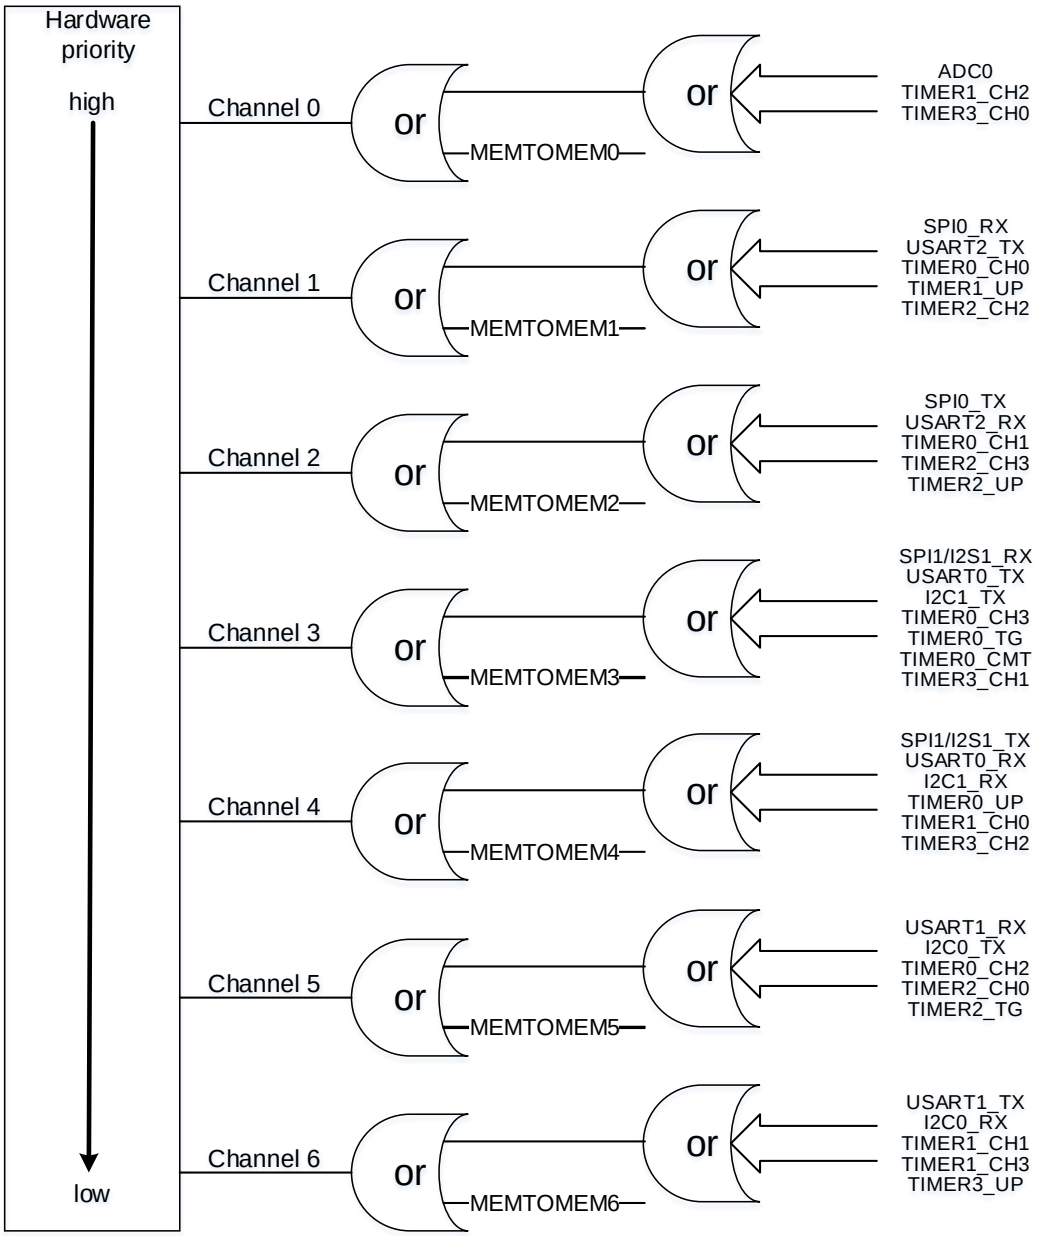


Table 12-4. DMA0 requests for each channel

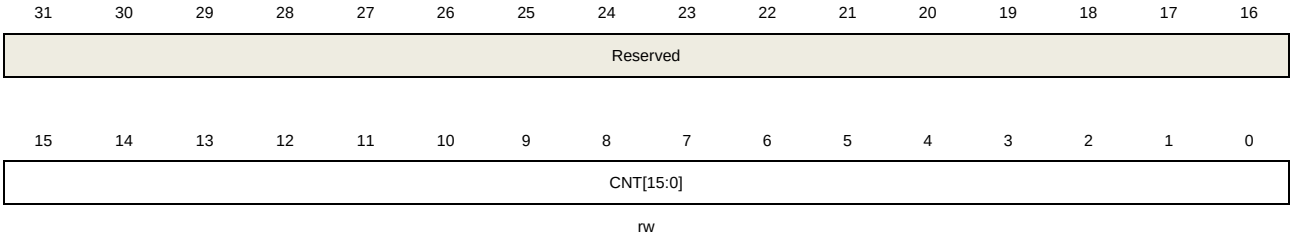
0	CHEN	Channel enable Software set and cleared 0:Disable channel 1:Enable channel

12.5.4. Channel x counter register (DMA_CHxCNT)

x = 0...6, where x is a channel number

Address offset: 0x0C + 0x14 × x

Reset value: 0x0000 0000



Bits	Fields	Descriptions
31:16	Reserved	Keep at reset value
15:0	CNT[15:0]	Transfer counter These bits can not be written when CHEN in the DMA_CHxCTL register is ‘1’. This register indicates how many transfers remain. Once the channel is enabled, it

is read-only, and decreases after each DMA transfer. If the register is zero, no transaction can be issued whether the channel is enabled or not. Once the transmission of the channel is complete, the register can be reloaded automatically by the previously programmed value if the channel is configured in circular mode.

12.5.5. Channel x peripheral base address register (DMA_CHxPADDR)

x = 0...6, where x is a channel number

Address offset: 0x10 + 0x14 × x

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MADDR[15:0]															
rw															

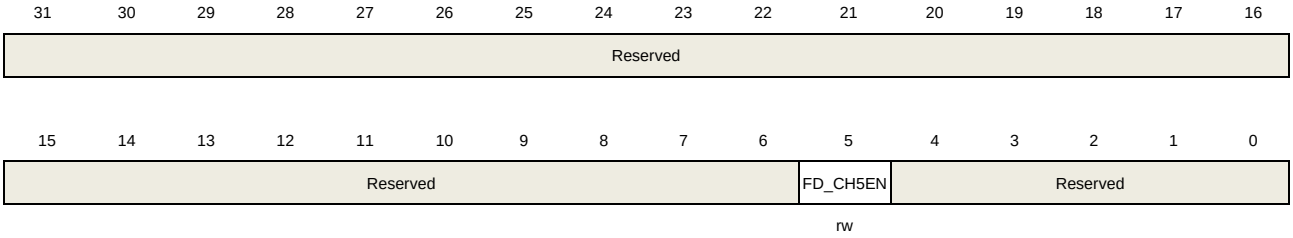
Bits	Fields	Descriptions
31:0	MADDR[31:0]	Memory base address

These bits can not be written when CHEN in the DMA_CHxCTL register is ‘1’.
When MWIDTH in the DMA_CHxCTL register is 01 (16-bit), the LSB of these bits is ignored. Access is automatically aligned to a half word address.
When MWIDTH in the DMA_CHxCTL register is 10 (32-bit), the two LSBs of these bits are ignored. Access is automatically aligned to a word address.

12.5.7. DMA additional configuration register (DMA_ACFG)

Address offset: 0x0300
Reset value: 0x0000 0000

Note: *This register is not sutiable for DMA0.*



Bits	Fields	Descriptions
31:6	Reserved	must be kept at reset value
5	FD_CH5EN	Enable bit for channel 5 Full_Data transfer mode This bit can not be written when CHEN in the DMA_CHxCTL register is ‘1’. 0: Disable the channel 5 Full_Data transfer mode 1: Enable the channel 5 Full_Data transfer mode
4:0	Reserved	must be kept at reset value

13. Debug (DBG)

13.1. Overview

The GD32F20x series provide a large variety of debug, trace and test features. They are implemented with a standard configuration of the ARM CoreSightTM module together with a daisy chained standard TAP controller. Debug and trace functions are integrated into the ARM Cortex-M3. The debug system supports serial wire debug (SWD) and trace functions in addition to standard JTAG debug. The debug and trace functions refer to the following documents:

- Cortex-M3 Technical Reference Manual
- ARM Debug Interface v5 Architecture Specification

The DBG hold unit helps debugger to debug power saving mode, TIMER, I2C, WWDGT, FWDGT and CAN. When corresponding bit is set, provide clock when in power saving mode or hold the state for TIMER, WWDGT, FWDGT, I2C or CAN.

13.2. JTAG/SW characteristics

Debug capabilities can be accessed by a debug tool via Serial Wire (SW - Debug Port) or JTAG interface (JTAG - Debug Port).

13.2.1. Switch JTAG or SW interface

By default, the JTAG interface is active. The sequence for switching from JTAG to SWD is:

- Send 50 or more TCK cycles with TMS = 1.
- Send the 16-bit sequence on TMS = 1110011110011110 (0xE79E LSB first).
- Send 50 or more TCK cycles with TMS = 1.

The sequence for switching from SWD to JTAG is:

- Send 50 or more TCK cycles with TMS = 1.
- Send the 16-bit sequence on TMS = 1110011100111100 (0xE73C LSB first).
- Send 50 or more TCK cycles with TMS = 1.

13.2.2. Pin assignment

The JTAG interface provides 5-pin standard JTAG, known as JTAG clock (JTCK), JTAG mode selection (JTMS), JTAG data input (JTDI), JTAG data output (JTDO) and JTAG reset (NJTRST, active low). The serial wire debug (SWD) provide 2-pin SW interface, known as

SW data input/output (SWDIO) and SW clock (SWCLK). The two SW pin are multiplexed with two of five JTAG pin, which is SWDIO multiplexed with JTMS, SWCLK multiplexed with JTCK. The JTDO is also used as Trace async data output (TRACESWO) when async trace enabled.

The pin assignment are:

PA15 : JTDI
PA14 : JTCK/SWCLK
PA13 : JTMS/SWDIO
PB4 : NJTRST
PB3 : JTDO

By default, 5-pin standard JTAG debug mode is chosen after reset. Users can also use JTAG function without NJTRST pin, then the PB4 can be used to other GPIO functions. (NJTRST tied to 1 by hardware). If switch to SW debug mode, the PA15/PB4/PB3 are released to other GPIO functions. If JTAG and SW not used, all 5-pin can be released to other GPIO functions. Please refer to ***GPIO chapter for pin configuration.***

13.2.3. JTAG daisy chained structure

The Cortex-M3 JTAG TAP is connected to a Boundary-Scan (BSD) JTAG TAP. The BSD JTAG IR is 5-bit width, while the Cortec-M3 JTAG IR is 4-bit width. So when JTAG in IR shift step, it first shift 5-bit BYPASS instruction (5'b 11111) for BSD JTAG, and then shift normal 4-bit instruction for Cortext-M3 JTAG. Because of the data shift under BSD JTAG BYPASS mode, adding 1 extra bit to the data chain is needed.

The BSD JTAG IDCODE is 0x790007A3.

13.2.4. Debug reset

The JTAG-DP and SW-DP register are in the power on reset domain. The System reset initializes the majority of the Cortex-M3, excluding NVIC and debug logic, (FPB, DWT, and ITM). The NJTRST reset can reset JTAG TAP controller only. So, it can perform debug feature under system reset. Such as, halt-after-reset, which is the debugger sets halt under system reset, and the core halts immediately after the system reset is released.

13.2.5. JEDEC-106 ID code

The Cortex-M3 integrates JEDEC-106 ID code, which is located in ROM table and mapped on the address of 0xE00FF000_0xE00FFFFF.

13.3. Debug hold function overview

13.3.1. Debug support for power saving mode

When STB_HOLD bit in DBG control register (DBG_CTL) is set and entering the standby

mode, the clock of AHB bus and system clock are provided by CK_IRC8M, and the debugger can debug in standby mode. When exit the standby mode, a system reset generated.

When DSLP_HOLD bit in DBG control register (DBG_CTL) is set and entering the Deep-sleep mode, the clock of AHB bus and system clock are provided by CK_IRC8M, and the debugger can debug in Deep-sleep mode.

When SLP_HOLD bit in DBG control register (DBG_CTL) is set and entering the sleep mode, the clock of AHB bus for CPU is not closed, and the debugger can debug in sleep mode.

13.3.2. Debug support for TIMER, I2C, WWDGT, FWDGT and CAN

When the core halted and the corresponding bit in DBG control register 1 (DBG_CTL) is set, the following behaved.

For TIMER, the timer counters stopped and hold for debug.

For I2C, SMBUS timeout hold for debug.

For WWDGT or FWDGT, the counter clock stopped for debug.

For CAN, the receive register stopped counting for debug.

13.4. Register definition

13.4.1. ID code register (DBG_ID)

Address: 0xE004 2000
Read only

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID_CODE[31:16]															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID_CODE[15:0]															
r															

Bits	Fields	Descriptions
31:0	ID_CODE[31:0]	DBG ID code register These bits read by software, These bits are unchanged constant

13.4.2. Control register (DBG_CTL)

Address offset: 0x04
Reset value: 0x0000 0000; power reset only

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved.	TIMER10_HOLD	TIMER9_HOLD	TIMER8_HOLD	TIMER13_HOLD	TIMER12_HOLD	TIMER11_HOLD	Reserved			CAN1_HOLD	TIMER7_HOLD	TIMER6_HOLD	TIMER5_HOLD	TIMER4_HOLD	I2C1_HOLD

rw	rw	rw	rw	rw	rw	rw	rw	rw		rw			rw	rw	rw

Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value
30	TIMER10_HOLD	TIMER 10 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 10 counter for debug when core halted
29	TIMER9_HOLD	TIMER 9 hold bit

		This bit is set and reset by software 0: no effect 1: hold the TIMER 9 counter for debug when core halted
28	TIMER8_HOLD	TIMER 8 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 8 counter for debug when core halted
27	TIMER13_HOLD	TIMER 13 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 13 counter for debug when core halted
26	TIMER12_HOLD	TIMER 12 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 12 counter for debug when core halted
25	TIMER11_HOLD	TIMER 11 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 11 counter for debug when core halted
24:22	Reserved	Must be kept at reset value
21	CAN1_HOLD	CAN1 hold bit This bit is set and reset by software 0: no effect 1: the receive register of CAN1 stops receiving data when core halted
20	TIMER7_HOLD	TIMER 7 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 7 counter for debug when core halted
19	TIMER6_HOLD	TIMER 6 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 6 counter for debug when core halted
18	TIMER5_HOLD	TIMER 5 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 5 counter for debug when core halted
17	TIMER4_HOLD	TIMER 4 hold bit This bit is set and reset by software 0: no effect

		1: hold the TIMER 4 counter for debug when core halted
16	I2C1_HOLD	I2C1 hold bit This bit is set and reset by software 0: no effect 1: hold the I2C1 SMBUS timeout for debug when core halted
15	I2C0_HOLD	I2C0 hold bit This bit is set and reset by software 0: no effect 1: hold the I2C0 SMBUS timeout for debug when core halted
14	CAN0_HOLD	CAN0 hold bit This bit is set and reset by software 0: no effect 1: the receive register of CAN0 stops receiving data when core halted
13	TIMER3_HOLD	TIMER 3 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 3 counter for debug when core halted
12	TIMER2_HOLD	TIMER 2 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 2 counter for debug when core halted
11	TIMER1_HOLD	TIMER 1 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 1 counter for debug when core halted
10	TIMER0_HOLD	TIMER 0 hold bit This bit is set and reset by software 0: no effect 1: hold the TIMER 0 counter for debug when core halted
9	WWDGT_HOLD	WWDGT hold bit This bit is set and reset by software 0: no effect 1: hold the WWDGT counter clock for debug when core halted
8	FWDGT_HOLD	FWDGT hold bit This bit is set and reset by software 0: no effect 1: hold the FWDGT counter clock for debug when core halted
7:6	TRACE_MODE[1:0]	Trace pin allocation mode This bit is set and reset by software

		00: Trace pin used in asynchronous mode 01: Trace pin used in synchronous mode and the data length is 1 10: Trace pin used in synchronous mode and the data length is 2 11: Trace pin used in synchronous mode and the data length is 4
5	TRACE_IOEN	Trace pin allocation enable This bit is set and reset by software 0: Trace pin allocation disable 1: Trace pin allocation enable
4:3	Reserved	Must be kept at reset value
2	STB_HOLD	Standby mode hold register This bit is set and reset by software 0: no effect 1: At the standby mode, the clock of AHB bus and system clock are provided by CK_IRC8M, a system reset generated when exit standby mode
1	DSLP_HOLD	Deep-sleep mode hold register This bit is set and reset by software 0: no effect 1: At the Deep-sleep mode, the clock of AHB bus and system clock are provided by CK_IRC8M
0	SLP_HOLD	Sleep mode hold register This bit is set and reset by software 0: no effect 1: At the sleep mode, the clock of AHB is on.

14. Analog-to-digital converter (ADC)

14.1. Overview

The 12-bit ADC is an analog-to-digital converter using the successive approximation method. It has 18 multiplexed channels making the ADC convert analog signals from 16 external channels, and 2 internal channels. The analog watchdog allows the application to detect whether the input voltage goes outside the user-defined higher or lower thresholds. The analog signals of the channels can be converted by the ADC in single, continuous, scan or discontinuous mode. A left-aligned or right-aligned 16-bit data register holds the output of the ADC. An on-chip hardware oversample scheme improves performances while off-loading the related computational burden from the MCU.

14.2. Characteristics

- High performance
  - —12-bit, 10-bit, 8-bit or 6-bit configurable resolution
  - —ADC sampling rate: 2 MSPs for 12-bit resolution, faster sampling rate can be obtained by lowering the resolution
  - —Self-calibration
  - —Programmable sampling time
  - —Data alignment with built-in data coherency
  - —DMA support
- Analog input channels
  - —16 external analog inputs
  - —1 channel for internal temperature sensor (V_{SENSE})
  - —1 channel for internal reference voltage (V_{REFINT})
- Start-of-conversion can be initiated
  - —By software
  - —By hardware triggers
- Conversion modes
  - —Converts a single channel or scans a sequence of channels.
  - —Single mode converts selected inputs once per trigger.
  - —Continuous mode converts selected inputs continuously
  - —Discontinuous mode
  - —SYNC mode(the device with two or more ADCs)
- Analog watchdog
- Interrupt generation：

—at the end of regular and inserted group conversions
—analog watchdog event

- Oversampler
  - —16-bit data register
  - —Oversampling ratio adjustable from 2 to 256x
  - —Programmable data shift up to 8-bit
- ADC supply requirements: 2.6V to 3.6V, and typical power supply voltage is 3.3V
- ADC input range: $V_{REFN} \leq V_{IN} \leq V_{REFP}$

14.3. Pins and internal signals

Figure 14-1. ADC module block diagram shows the ADC block diagram and *Table 14-2. ADC pins definition* gives the ADC pin description.

Table 14-1. ADC internal signals

Internal signal name	Signal type	Description
V_{SENSE}	Input	Internal temperature sensor output voltage
V_{REFINT}	Input	Internal voltage reference output voltage

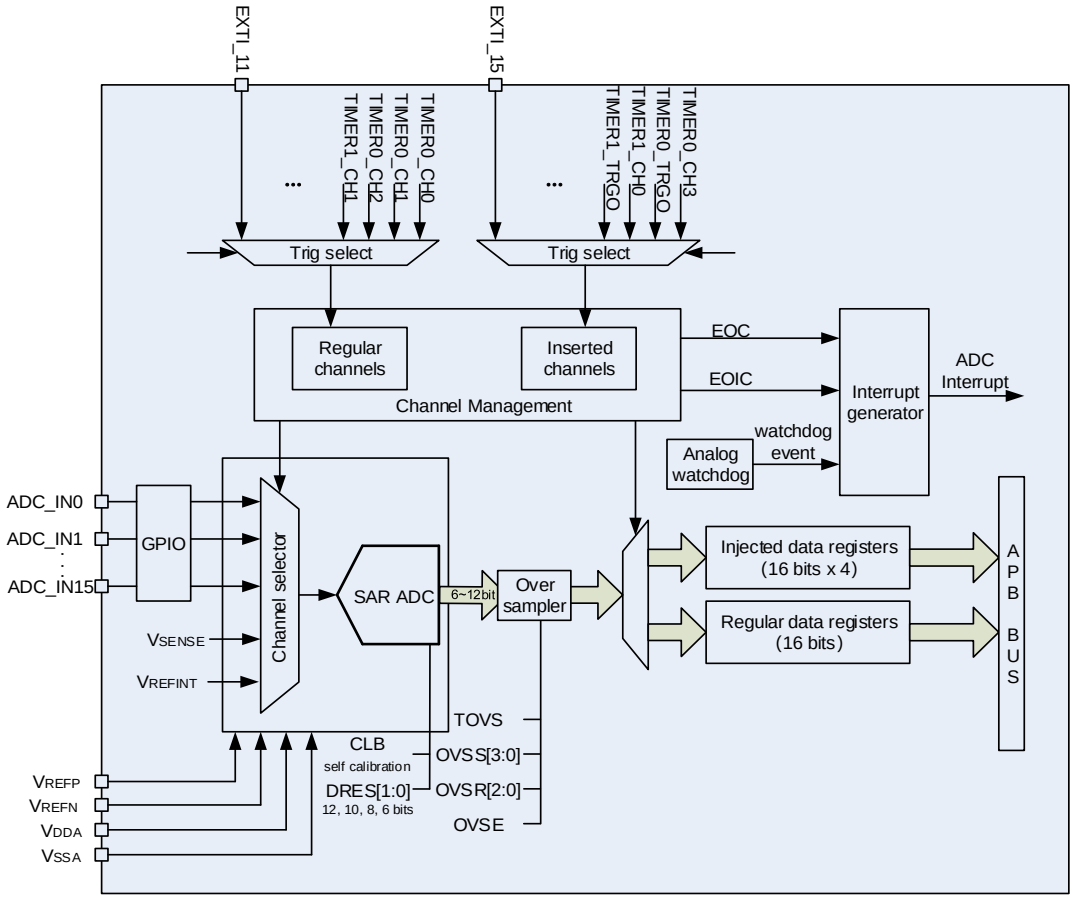
Table 14-2. ADC pins definition

Name	Signal type	Remarks
V_{DDA}	Input, analog power supply	Analog power supply equal to V_{DD} and 2.6 V ≤ V_{DDA}≤ 3.6 V
V_{SSA}	Input, analog power supply ground	Ground for analog power supply equal to V_{SS}
V_{REFP}	Input, analog reference positive	The positive reference voltage for the ADC, 2.6 V ≤ V_{REFP} ≤ V_{DDA}
V_{REFN}	Input, analog reference negative	The negative reference voltage for the ADC, V_{REFN} = V_{SSA}
ADCx_IN [15:0]	Input, Analog signals	Up to 16 external channels

Note: V_{DDA} and V_{SSA} have to be connected to V_{DD} and V_{SS}, respectively.

14.4. Function overview

Figure 14-1. ADC module block diagram



14.4.1. Calibration (CLB)

The ADC has a foreground calibration feature. During the procedure, the ADC calculates a calibration factor which is internally applied to the ADC until the next ADC power-off. The application must not use the ADC during calibration and must wait until it is completed. Calibration should be performed before starting A/D conversion. The calibration is initiated by software by setting bit CLB=1. CLB bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon as the calibration is completed.

When the ADC operating conditions change (such as supply power voltage V_{DDA}, positive reference voltage V_{REFP}, temperature and so on), it is recommended to re-run a calibration cycle.

The internal analog calibration can be reset by setting the RSTCLB bit in ADC_CTL1 register.

Calibration software procedure:

1. Ensure that ADCON=1.

2. Delay 14 ADCCLK to wait for ADC stability.
3. Set RSTCLB (optional).
4. Set CLB=1.
5. Wait until CLB=0.

14.4.2. ADC clock

The ADCCLK clock provided by the clock controller is synchronous with the AHB and APB2 clock. The maximum frequency is 28MHz. The RCU controller has a dedicated programmable prescaler for the ADC clock.

14.4.3. ADCON switch

The ADCON bit on the ADC_CTL1 register is the enable switch of the ADC module. The ADC module will keep in reset state if this bit is 0. For power saving, when this bit is reset, the analog sub-module will be put into power-down mode.

14.4.4. Regular and inserted channel groups

The ADC supports 18 multiplexed channels and organizes the conversion results into two groups: a regular channel group and an inserted channel group.

In the regular group, a sequence of up to 16 conversions can be organized in a specific sequence. The ADC_RSQ0~ADC_RSQ2 registers specify the selected channels of the regular group. The RL[3:0] bits in the ADC_RSQ0 register specify the total conversion sequence length.

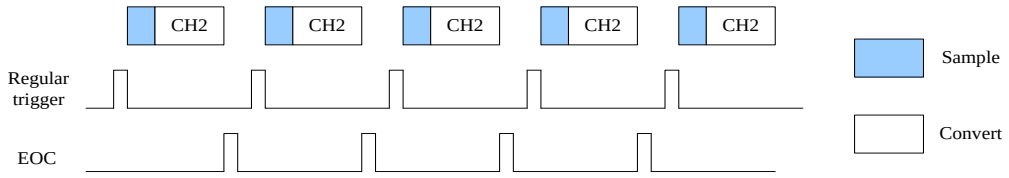
In the inserted group, a sequence of up to 4 conversions can be organized in a specific sequence. The ADC_ISQ register specify the selected channels of the inserted group. The IL[1:0] bits in the ADC_ISQ register specify the total conversion sequence length.

14.4.5. Conversion modes

Single conversion mode

This mode can be running on both regular and inserted channel group. In the single conversion mode, the ADC performs conversion on the channel specified in the RSQ0[4:0] bits of ADC_RSQ2 at a regular trigger or the channel specified in the ISQ3[4:0] bits of ADC_ISQ. When the ADCON has been set high, the ADC samples and converts a single channel, once the corresponding software trigger or external trigger is active.

Figure 14-2. Single conversion mode



After conversion of a single regular channel, the conversion data will be stored in the ADC_RDATA register, the EOC will be set. An interrupt will be generated if the EOCIE bit is set.

After conversion of a single inserted channel, the conversion data will be stored in the ADC_IDATA0 register, the EOC and EOIC will be set. An interrupt will be generated if the EOCIE or EOICIE bit is set.

Software procedure for a single conversion of a regular channel:

1. Make sure the DISRC, SM in the ADC_CTL0 register and CTN bit in the ADC_CTL1 register are reset
2. Configure RSQ0 with the analog channel number
3. Configure ADC_SAMPTx register
4. Configure ETERC and ETSRC bits in the ADC_CTL1 register if in need
5. Set the SWRCST bit, or generate an external trigger for the regular group
6. Wait the EOC flag to be set
7. Read the converted in the ADC_RDATA register
8. Clear the EOC flag by writing 0 to it

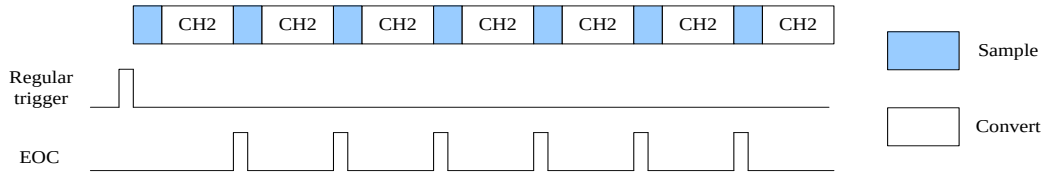
Software procedure for a single conversion of an inserted channel:

1. Make sure the DISIC, SM in the ADC_CTL0 register are reset
2. Configure ISQ3 with the analog channel number
3. Configure ADC_SAMPTx register
4. Configure ETEIC and ETSIC bits in the ADC_CTL1 register if in need
5. Set the SWICST bit, or generate an external trigger for the inserted group
6. Wait the EOC/EOIC flags to be set
7. Read the converted in the ADC_IDATA0 register
8. Clear the EOC/EOIC flags by writing 0 to them

Continuous conversion mode

This mode can be run on the regular channel group. The continuous conversion mode will be enabled when CTN bit in the ADC_CTL1 register is set. In this mode, the ADC performs conversion on the channel specified in the RSQ0[4:0]. When the ADCON has been set high, the ADC samples and converts specified channel, once the corresponding software trigger or external trigger is active. The conversion data will be stored in the ADC_RDATA register.

Figure 14-3. Continuous conversion mode



Software procedure for continuous conversion on a regular channel:

1. Set the CTN bit in the ADC_CTL1 register
2. Configure RSQ0 with the analog channel number
3. Configure ADC_SAMPTx register
4. Configure ETERC and ETSRC bits in the ADC_CTL1 register if in need
5. Set the SWRCST bit, or generate an external trigger for the regular group
6. Wait the EOC flag to be set
7. Read the converted in the ADC_RDATA register
8. Clear the EOC flag by writing 0 to it
9. Repeat steps 6~8 as soon as the conversion is in need

To get rid of checking, DMA can be used to transfer the converted data:

1. Set the CTN and DMA bit in the ADC_CTL1 register
2. Configure RSQ0 with the analog channel number
3. Configure ADC_SAMPTx register
4. Configure ETERC and ETSRC bits in the ADC_CTL1 register if in need
5. Prepare the DMA module to transfer data from the ADC_RDATA.
6. Set the SWRCST bit, or generate an external trigger for the regular group

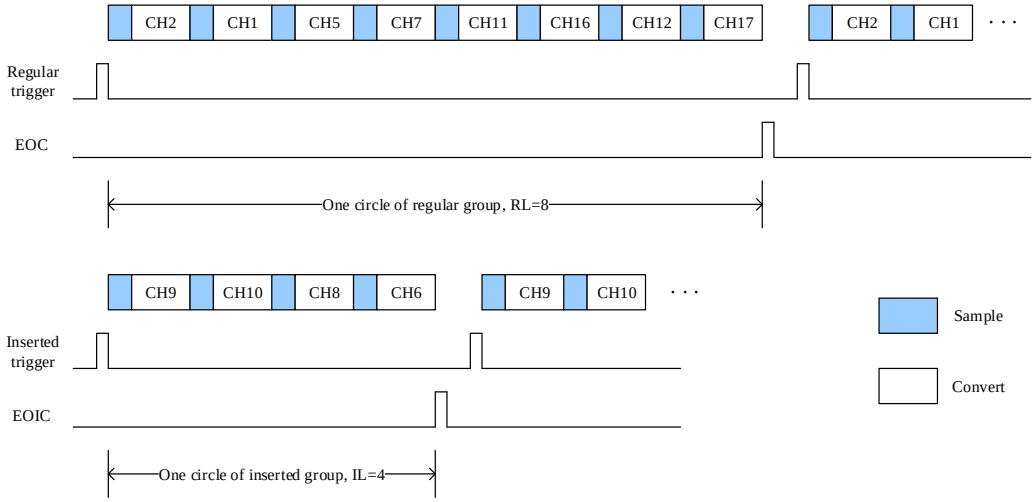
Scan conversion mode

The scan conversion mode will be enabled when SM bit in the ADC_CTL0 register is set. In

this mode, the ADC performs conversion on the channels with a specific sequence specified in the ADC_RSQ0~ADC_RSQ2 registers or ADC_ISQ register. When the ADCON has been set high, the ADC samples and converts specified channels one by one in the regular or inserted group till the end of the regular or inserted group, once the corresponding software trigger or external trigger is active. The conversion data will be stored in the ADC_RDATA or ADC_IDATAx register. After conversion of the regular or inserted channel group, the EOC or EOIC will be set. An interrupt will be generated if the EOCIE or EOICIE bit is set. The DMA bit in ADC_CTL1 register must be set when the regular channel group works in scan mode.

After conversion of a regular channel group, the conversion can be restarted automatically if the CTN bit in the ADC_CTL1 register is set.

Figure 14-4. Scan conversion mode, continuous disable



Software procedure for scan conversion on a regular channel group:

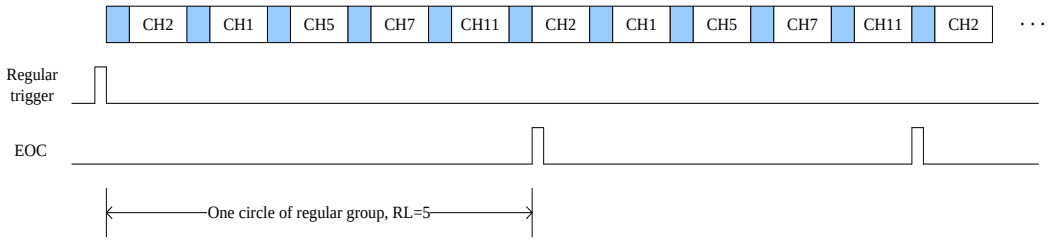
1. Set the SM bit in the ADC_CTL0 register and the DMA bit in the ADC_CTL1 register
2. Configure ADC_RSQx and ADC_SAMPTx registers
3. Configure ETERC and ETSRC bits in the ADC_CTL1 register if in need
4. Prepare the DMA module to transfer data from the ADC_RDATA.
5. Set the SWRCST bit, or generate an external trigger for the regular group
6. Wait the EOC flag to be set
7. Clear the EOC flag by writing 0 to it

Software procedure for scan conversion on an inserted channel group:

1. Set the SM bit in the ADC_CTL0 register
2. Configure ADC_ISQ and ADC_SAMPTx registers
3. Configure ETEIC and ETSIC bits in the ADC_CTL1 register if in need
4. Set the SWICST bit, or generate an external trigger for the inserted group

5. Wait the EOC/EOIC flags to be set
6. Read the converted in the ADC_IDATAx register
7. Clear the EOC/EOIC flag by writing 0 to them

Figure 14-5. Scan conversion mode, continuous enable



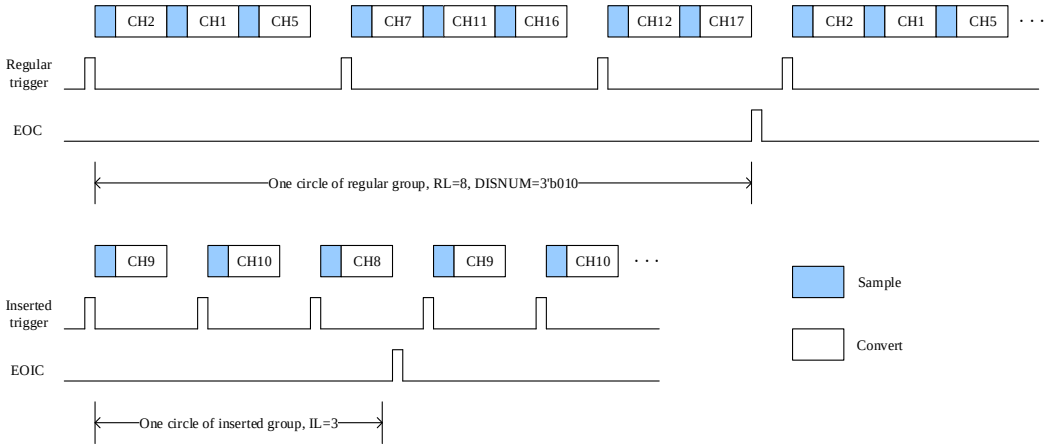
Discontinuous mode

For regular channel group, the discontinuous conversion mode will be enabled when DISRC bit in the ADC_CTL0 register is set. In this mode, the ADC performs a short sequence of n conversions (n<=8) which is a part of the sequence of conversions selected in the ADC_RSQ0~ADC_RSQ2 registers. The value of n is defined by the DISNUM[2:0] bits in the ADC_CTL0 register. When the corresponding software trigger or external trigger is active, the ADC samples and coverts the next n channels selected in the ADC_RSQ0~ADC_RSQ2 registers until all the channels in the regular sequence are done. The EOC will be set after every circle of the regular channel group. An interrupt will be generated if the EOCIE bit is set.

For inserted channel group, the discontinuous conversion mode will be enabled when DISIC bit in the ADC_CTL0 register is set. In this mode, the ADC performs one conversion which is a part of the sequence of conversions selected in the ADC_ISQ register. When the corresponding software trigger or external trigger is active, the ADC samples and coverts the next channel selected in the ADC_ISQ register until all the channels in the inserted sequence are done. The EOIC will be set after every circle of the inserted channel group. An interrupt will be generated if the EOICIE bit is set.

The regular and inserted groups cannot both work in discontinuous conversion mode. Only one group conversion can be set in discontinuous conversion mode at a time.

Figure 14-6. Discontinuous conversion mode



Software procedure for discontinuous conversion on a regular channel group:

1. Set the DISRC bit in the ADC_CTL0 register and the DMA bit in the ADC_CTL1 register
2. Configure DISNUM[2:0] bits in the ADC_CTL0 register
3. Configure ADC_RSQx and ADC_SAMPTx registers
4. Configure ETERC and ETSRC bits in the ADC_CTL1 register if in need
5. Prepare the DMA module to transfer data from the ADC_RDATA (refer to the spec of the DMA module).
6. Set the SWRCST bit, or generate an external trigger for the regular group
7. Repeat step6 if in need.
8. Wait the EOC flag to be set
9. Clear the EOC flag by writing 0 to it

Software procedure for discontinuous conversion on an inserted channel group:

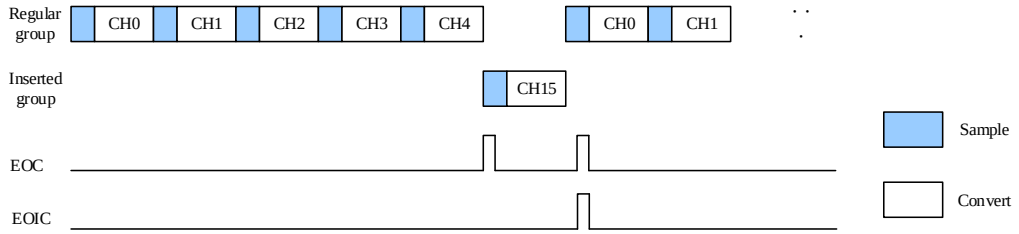
1. Set the DISIC bit in the ADC_CTL0 register
2. Configure ADC_ISQ and ADC_SAMPTx registers
3. Configure ETEIC and ETSIC bits in the ADC_CTL1 register if in need
4. Set the SWICST bit, or generate an external trigger for the inserted group
5. Repeat step4 if in need
6. Wait the EOC/EOIC flags to be set
7. Read the converted in the ADC_IDATAx register
8. Clear the EOC/EOIC flag by writing 0 to them

14.4.6. Inserted channel management

Auto-insertion

The inserted group channels are automatically converted after the regular group channels when the ICA bit in ADC_CTL0 register is set. In this mode, external trigger on inserted channels cannot be enabled. A sequence of up to 20 conversions programmed in the ADC_RSQ0~ADC_RSQ2 and ADC_ISQ registers can be used to convert in this mode. In addition to the ICA bit, if the CTN bit is also set, regular channels followed by inserted channels are continuously converted.

Figure 14-7. Auto-insertion, CTN = 1

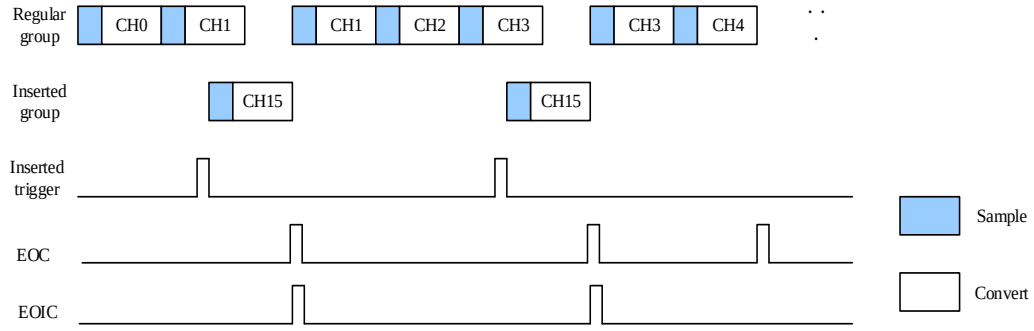


The auto insertion mode cannot be enabled when the discontinuous conversion mode is set.

Triggered insertion

If the ICA bit is cleared, the triggered insertion occurs if a software or external trigger occurs during the regular group channel conversion. In this situation, the ADC aborts from the current conversion and starts the conversion of inserted channel sequence. After the inserted channel group is done, the regular group channel conversion is resumed from the last aborted conversion.

Figure 14-8. Triggered insertion



14.4.7. Analog watchdog

The analog watchdog is enabled when the RWDEN and IWDEN bits in the ADC_CTL0 register are set for regular and inserted channel groups respectively. When the analog voltage converted by the ADC is below a low threshold or above a high threshold, the WDE bit in ADC_STAT register will be set. An interrupt will be generated if the WDEIE bit is set. The

ADC_WDHT and ADC_WDLT registers are used to specify the high and low threshold. The comparison is done before the alignment, so the threshold value is independent of the alignment, which is specified by the DAL bit in the ADC_CTL1 register. One or more channels, which are select by the RWDEN, IWDEN, WDSC and WDCHSEL[4:0] bits in ADC_CTL0 register, can be monitored by the analog watchdog.

14.4.8. Data alignment

The alignment of data stored after conversion can be specified by DAL bit in the ADC_CTL1 register.

After being decreased by the user-defined offset written in the ADC_IOFFx registers, the inserted group data value may be a negative value. The sign value is extended.

When left-aligned, the 12/10/8/6-bit data are aligned on a half-word, as shown blew ***Figure 14-9. Data alignment of 12-bit*** **resolution**, ***Figure 14-10. Data alignment of 10-bit resolution***, ***Figure 14-11. Data alignment of 8-bit resolution*** and ***Figure 14-12. Data alignment of 6-bit resolution***.

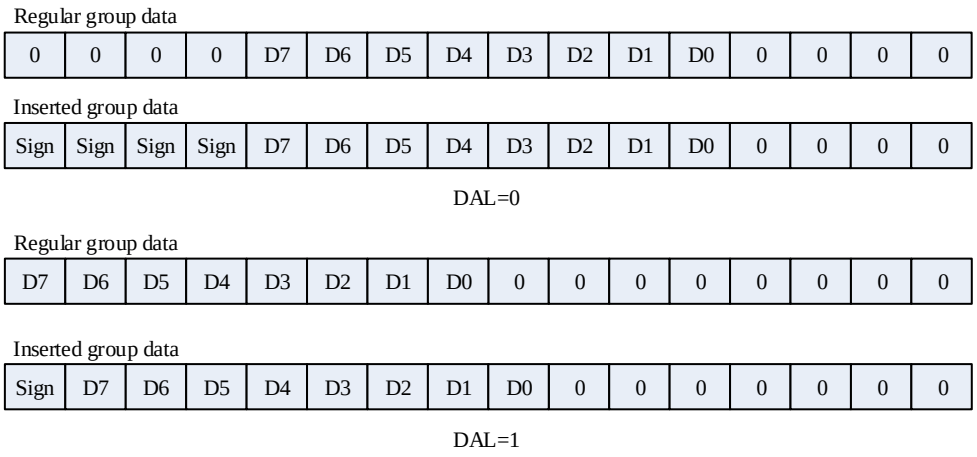

Figure 14-12. Data alignment of 6-bit resolution

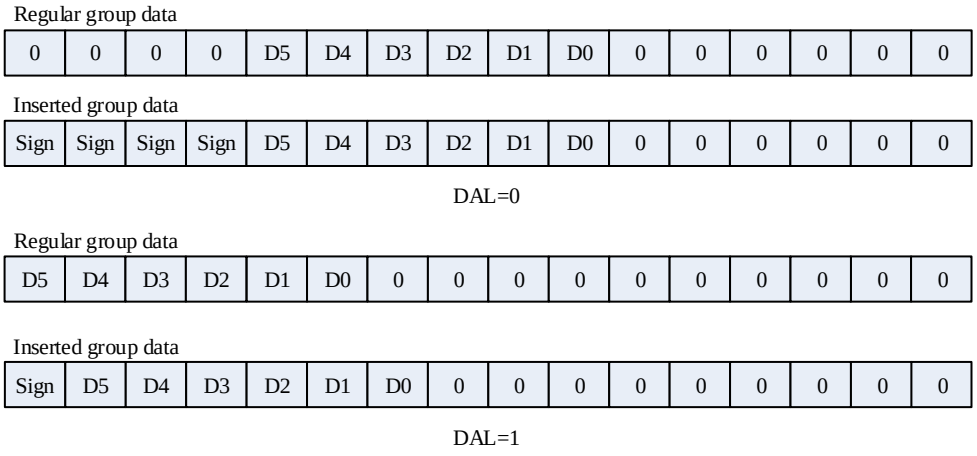

14.4.9. Programmable sample time

The number of ADCCLK cycles which is used to sample the input voltage can be specified by the SPTn[2:0] bits in the ADC_SAMPT0 and ADC_SAMPT1 registers. A different sample time can be specified for each channel. For 12-bits resolution, the total conversion time is “sampling time + 12.5” ADCCLK cycles.

Example:

ADCCLK = 14MHz and sample time is 1.5 cycles, the total conversion time is “1.5+12.5” ADCCLK cycles, that means 1us.

14.4.10. External trigger

The conversion of regular or inserted group can be triggered by rising edge of external trigger inputs. The external trigger source of regular channel group is controlled by the ETSRC[2:0] bits in the ADC_CTL1 register, while the external trigger source of inserted channel group is

controlled by the ETSIC[2:0] bits in the ADC_CTL1 register

ETSRC[2:0] and ETSIC[2:0] control bits are used to specify which out of 8 possible events can trigger conversion for the regular and inserted groups.

Table 14-3. External trigger for regular channels for ADC0 and ADC1

14.4.11. DMA request

The DMA request, which is enabled by the DMA bit of ADC_CTL1 register, is used to transfer data of regular group for conversion of more than one channel. The ADC generates a DMA request at the end of conversion of a regular channel. When this request is received, the DMA will transfer the converted data from the ADC_RDATA register to the destination location which is specified by the user.

Note: Only ADC0 and ADC2 have this DMA capability. ADC1 converted data can be transferred in ADC sync mode.

14.4.12. Temperature sensor, and internal reference voltage V_{REFINT}

When the TSVREN bit of ADC_CTL1 register is set, the temperature sensor channel (ADC0_CH16) and V_{REFINT} channel (ADC0_CH17) is enabled. The temperature sensor can be used to measure the ambient temperature of the device. The sensor output voltage can be converted into a digital value by ADC. The sampling time for the temperature sensor is recommended to be set to at least 17.1 µs. When this sensor is not in use, it can be put in power down mode by resetting the TSVREN bit.

The output voltage of the temperature sensor changes linearly with temperature. Because there is an offset, which is up to 45 °C and varies from chip to chip due to process variation, the internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperature. When it is used to detect accurate temperature, an external temperature sensor part should be used to calibrate the offset error.

The internal voltage reference (V_{REFINT}) provides a stable (bandgap) voltage output for the ADC and Comparators. V_{REFINT} is internally connected to the ADC0_CH17 input channel.

Software procedure for use the temperature sensor:

1. Configure the conversion sequence(ADC_IN16) and the sampling time(17.1µs) for the channel.
2. Enable the temperature sensor by setting the TSVREN bit in the ADC control register 1 (ADC_CTL1).
3. Start the ADC conversion by setting the ADCON bit (or by external trigger).
4. Read the resulting temperature data($V_{temperature}$) in the ADC data register, and get the temperature using the following formula:

$$\text{Temperature (°C)} = \{(V_{25} - V_{temperature}(\text{digit})) / \text{Avg\_Slope}\} + 25.$$

V_{25}: $V_{temperature}$ value at 25°C, the typical value is 1.43 V.

Avg_Slope: Average Slope for curve between Temperature vs. $V_{temperature}$, the typical value is 4.3 mV/°C.

14.4.13. Programmable resolution (DRES) - fast conversion mode

It is possible to obtain faster conversion time (t_{ADC}) by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the DRES[1:0] bits in the ADC_OVSAMPCTL register. Lower resolution allows faster conversion time for applications where high data precision is not required. The DRES[1:0] bits must only be changed when the ADCON bit is reset. Lower resolution reduces the conversion time needed for the successive approximation steps as shown in ***Table 14-7. tCONV timings depending on resolution***.

Table 14-7. t_{CONV} timings depending on resolution

DRES [1:0] bits	t_{CONV} (ADC clock cycles)	t_{CONV}(ns) at f_{ADC} = 28MHz	t_{SMPL}(min) (ADC clock cycles)	t_{ADC}(ADC clock cycles)	t_{ADC}(us) at f_{ADC} = 28MHz
12	12.5	446 ns	1.5	14	500 ns
10	10.5	375 ns	1.5	12	429 ns
8	8.5	304 ns	1.5	10	357 ns
6	6.5	232 ns	1.5	8	286 ns

14.4.14. On-chip hardware oversampling

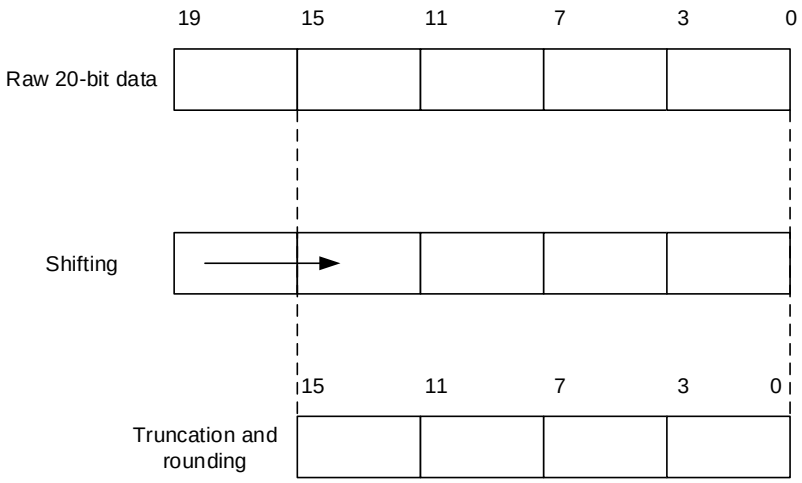
The on-chip hardware oversampling circuit performs data preprocessing to offload the CPU. It can handle multiple conversions and average them into a single data with increased data width, up to 16-bit. It provides a result with the following form, where N and M can be adjusted, and $D_{out}(n)$ is the n-th output digital signal of the ADC:

$$Result = \frac{1}{M} * \sum_{n=0}^{N-1} D_{out}(n) \quad (12\text{-}1)$$

The on-chip hardware oversampling circuit performs the following functions: summing and bit right shifting. The oversampling ratio N is defined by the OVSR[2:0] bits in the ADC_OVSAMPCTL register. It can range from 2x to 256x. The division coefficient M means bit right shifting up to 8-bit. It is configured through the OVSS[3:0] bits in the ADC_OVSAMPCTL register.

The summation unit can yield a result up to 20 bits (256 x 12-bit), which is first shifted right. The upper bits of the result are then truncated, keeping only the 16 least significant bits rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the data register.

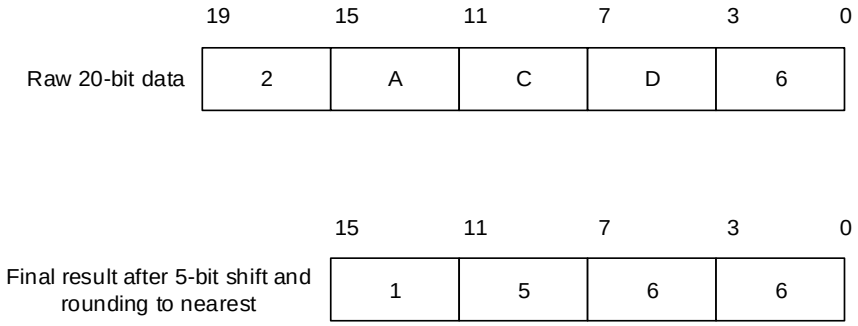
Figure 14-13. 20-bit to 16-bit result truncation



Note: If the intermediate result after the shifting exceeds 16 bits, the upper bits of the result are simply truncated.

Figure 14-14. Numerical example with 5-bits shift and rounding shows a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 14-14. Numerical example with 5-bits shift and rounding



The *Table 14-8. Maximum output results vs N and M Grayed values indicates truncation* below gives the data format for the various N and M combination, for a raw conversion data equal to 0xFFF.

Table 14-8. Maximum output results vs N and M Grayed values indicates truncation

Oversampling ratio	Max Raw data	No-shift OVSS=0000	1-bit shift OVSS=0001	2-bit shift OVSS=0010	3-bit shift OVSS=0011	4-bit shift OVSS=0100	5-bit shift OVSS=0101	6-bit shift OVSS=0110	7-bit shift OVSS=0111	8-bit shift OVSS=1000
2x	0x1FFE	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040	0x0020

Oversampling ratio	Max Raw data	No-shift OVSS= 0000	1-bit shift OVSS= 0001	2-bit shift OVSS= 0010	3-bit shift OVSS= 0011	4-bit shift OVSS= 0100	5-bit shift OVSS= 0101	6-bit shift OVSS= 0110	7-bit shift OVSS= 0111	8-bit shift OVSS= 1000
16x	0xFFF0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100
32x	0x1FFE0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200
64x	0x3FFC0	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400
128x	0x7FF80	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800
256x	0xFFF00	0xFF00	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF

The conversion timings in oversampled mode do not change compared to standard conversion mode: the sample time is maintained equal during the whole oversampling sequence. New data are provided every N conversion, with an equivalent delay equal to N x t_{ADC} = N x (t_{SMPL} + t_{CONV}).

14.5. ADC sync mode

In devices with two ADC, ADC sync mode can be used.

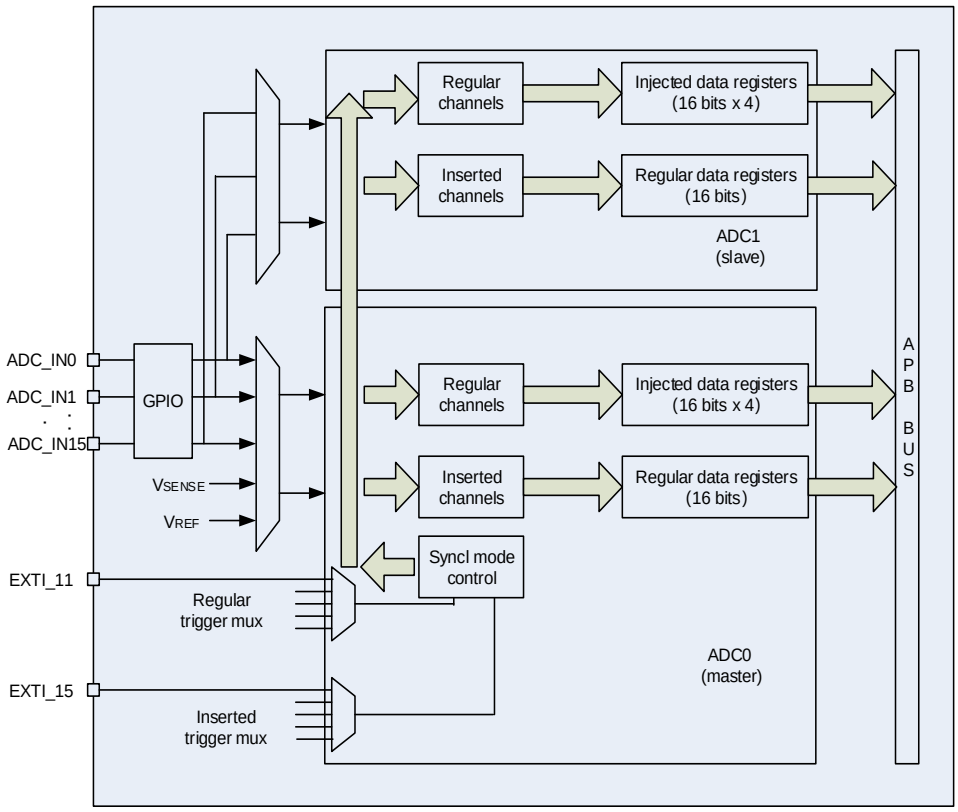
In ADC sync mode, the conversion starts alternately or simultaneously triggered by ADC0 master to ADC1 slave, according to the mode selected by the SYNCM[3:0] bits in ADC1_CTL0 register.

In sync mode, when configure the conversion which is triggered by an external event, the slave ADC must be configured as triggered by the software in order to prevent false triggers to start unwanted conversion. However, the external trigger must be enabled for ADC master and ADC slave.
The following modes can be configured:

- Free mode
- Regular parallel mode
- Inserted parallel mode
- Follow-up fast mode
- Follow-up slow mode
- Trigger rotation mode
- Inserted parallel mode + regular parallel mode
- Regular parallel mode + trigger rotation mode
- Inserted parallel mode + follow-up fast mode
- Inserted parallel mode + follow-up slow mode

In ADC sync mode, the DMA bit must be set even if it is not used; the converted data of ADC slave can be read from the master data register.

Figure 14-15. ADC sync block diagram



14.5.1. Free mode

In this mode, the ADC synchronization is bypassed, and each ADC works freely.

14.5.2. Regular parallel mode

This mode converts the regular channel simultaneously. The source of external trigger comes from the regular group MUX of ADC0 (selected by the ETSRC[2:0] bits in the ADC_CTL1 register). A simultaneous trigger is provided to ADC1.

At the end of conversion event on ADC0 or ADC1 an EOC interrupt is generated (if enabled on one of the two ADC interfaces) when the ADC0/ADC1 regular channels are all converted. The behavior of regular parallel mode shows in the ***Figure 14-16. Regular parallel mode on 16 channels***.

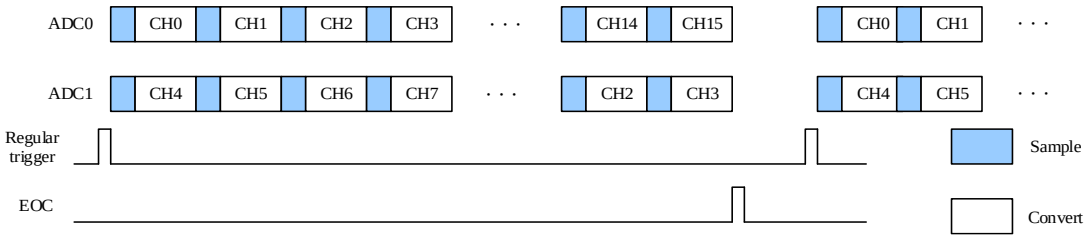
A 32-bit DMA is used, which transfers ADC_RDATA 32-bit register (the ADC_RDATA 32-bit register containing the ADC1 converted data in the upper half-word and the ADC0 converted data in the lower half-word) to SRAM.

Note:

1. Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

2. In parallel mode, exactly the same sampling time should be configured for the two channels that will be sampled simultaneously by ACD0 and ADC1.

Figure 14-16. Regular parallel mode on 16 channels



14.5.3. Inserted parallel mode

This mode converts the inserted channel simultaneously. The source of external trigger comes from the inserted group MUX of ADC0 (selected by the ETSIC[2:0] bits in the ADC_CTL1 register). A simultaneous trigger is provided to ADC1.

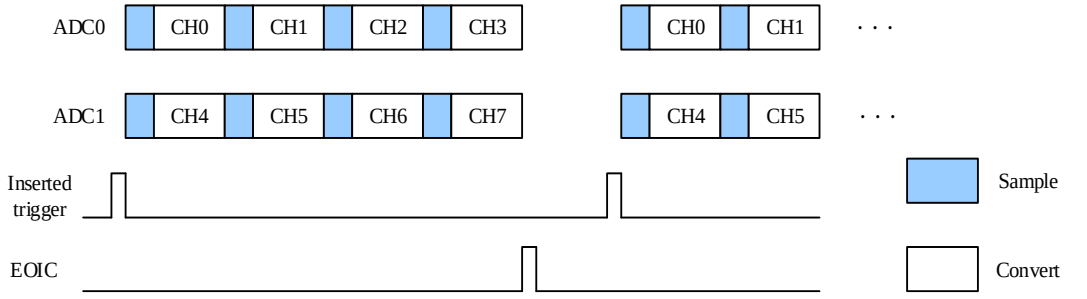
At the end of conversion event on ADC0 or ADC1, an EOIC interrupt is generated (if enabled on one of the two ADC interfaces). ADC0/ADC1 inserted channels are all converted, and the converted data is stored in the ADC_IDATAx registers of each ADC interface. The behavior of inserted parallel mode shows in the ***Figure 14-17. Inserted parallel mode on 4 channels***.

Note:

1. Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

2. In parallel mode, exactly the same sampling time should be configured for the two channels that will be sampled simultaneously by ADC0 and ADC1.

Figure 14-17. Inserted parallel mode on 4 channels



14.5.4. Follow-up fast mode

This mode can be running on the regular channel group (usually one channel). The source of

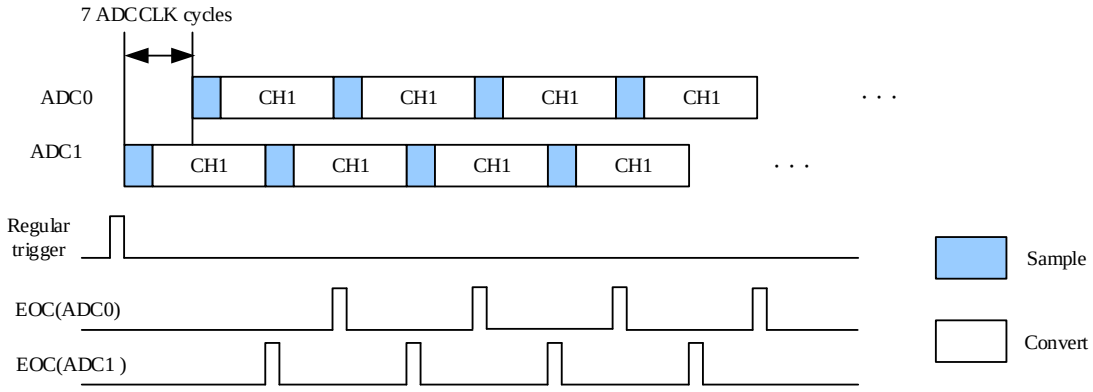
external trigger comes from the regular channel MUX of ADC0 (selected by the ETSRC[2:0] bits in the ADC_CTL1 register). When the trigger occurs, ADC1 runs immediately and ADC0 runs after 7 ADC clock cycles.

If the continuous mode is enabled for both ADC0 and ADC1, the selected regular channels of both ADCs are continuously converted. The behavior of follow-up fast mode shows in the ***Figure 14-18. Follow-up fast mode on 1 channel in continuous conversion mode***.

After an EOC interrupt is generated by ADC0 in case of setting the EOCIE bit, we can use a 32-bit DMA, which transfers to SRAM the ADC_RDATA 32-bit register containing the ADC1 converted data in the upper half word and the ADC0 converted data in the lower half word.

Note: The maximum sampling time allowed is <7 ADCCLK cycles to avoid the overlap between ADC0 and ADC1 sampling phases in the event that they convert the same channel.

Figure 14-18. Follow-up fast mode on 1 channel in continuous conversion mode



14.5.5. Follow-up slow mode

This mode can be running on the regular channel group (usually one channel). The source of external trigger comes from the regular channel MUX of ADC0(selected by the ETSRC[2:0] bits in the ADC_CTL1 register).When the trigger occurs, ADC1 runs immediately, ADC0 runs after 14 ADC clock cycles, after the second 14 ADC clock cycles the ADC1 runs again.

Continuous mode can't be used in this mode, because it continuously converts the regular channel. The behavior of follow-up slow mode shows in the ***Figure 14-19. Follow-up slow mode on 1 channel***.

After an EOC interrupt is generated by ADC0 (if enabled through the EOCIE bit), we can use a 32-bit DMA, which transfers to SRAM the ADC_RDATA 32-bit register containing the ADC1 converted data in the upper half-word and the ADC0 converted data in the lower half-word.

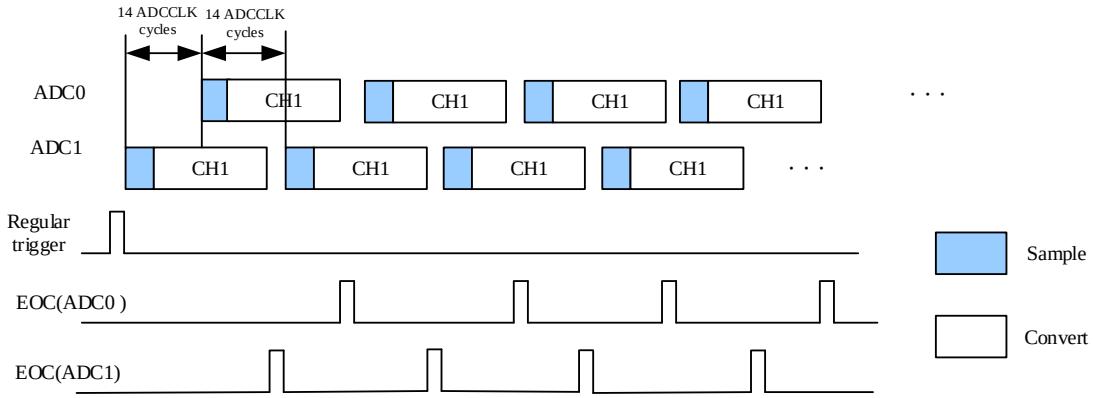
Note:

1. The maximum sampling time allowed is <14 ADCCLK cycles to avoid the overlap between ADC0 and ADC1 sampling phases in the event that they convert the same channel.

2. For both the fast and follow-up slow mode, we must ensure that no external trigger for

inserted channel occurs.

Figure 14-19. Follow-up slow mode on 1 channel



14.5.6. Trigger rotation mode

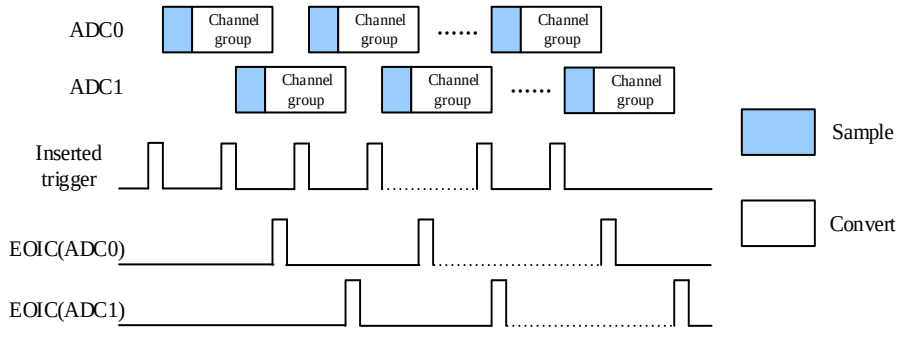
This mode can be running on the inserted channel group. The source of external trigger comes from the inserted channel MUX of ADC0 (selected by the ETSIC[2:0] bits in the ADC_CTL1 register).

When the first trigger occurs, all the inserted channels of ADC0 are converted. When the second trigger occurs, all the inserted channels of ADC1 are converted. The behavior of trigger rotation mode shows in the ***Figure 14-20. Trigger rotation: inserted channel group***.

If the EOIC interrupt of ADC0 and ADC1 are enabled, when all the channels of ADC0 or ADC1 have been converted, the corresponded interrupt occurred.

If another external trigger occurs after all inserted group channels have been converted, the trigger rotation process restarts by converting ADC0 inserted group channels.

Figure 14-20. Trigger rotation: inserted channel group



If the discontinuous mode is enabled for both ADC0 and ADC1, when the first trigger occurs, the first inserted channel in ADC0 is converted. When the second trigger occurs, the first inserted channel in ADC1 is converted. Then the second channel in ADC0, the second channel in ADC1, and so on.

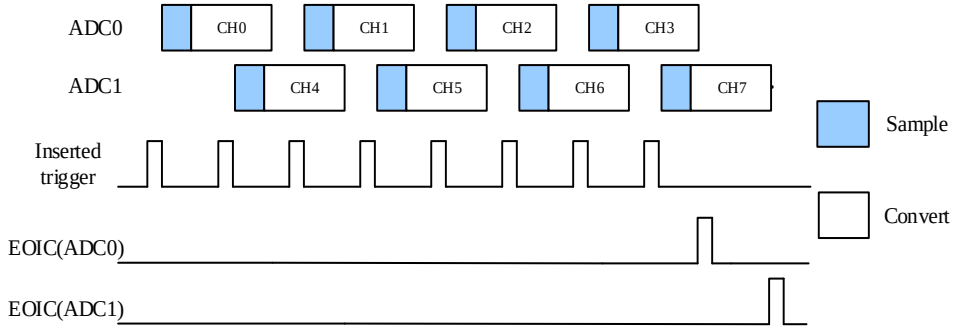
The behavior of trigger rotation discontinuous mode shows in the ***Figure 14-21. Trigger***

rotation: inserted channels in discontinuous mode.

If the EOIC interrupt of ADC0 and ADC1 are enabled. When all the channels of ADC0 or ADC1 have been converted, the corresponded interrupt occurred.

If another external trigger occurs after all inserted group channels have been converted then the trigger rotation process restarts.

Figure 14-21. Trigger rotation: inserted channels in discontinuous mode



14.5.7. Combined regular parallel & inserted parallel mode

In the free mode, the conversion of regular group can be interrupted by the conversion of inserted group. In the sync mode, it is also possible to interrupt parallel conversion of a regular group to insert parallel conversion of an inserted group.

Note: In combined regular parallel + inserted parallel mode, the sampling time for the two ADCs should be configured the same.

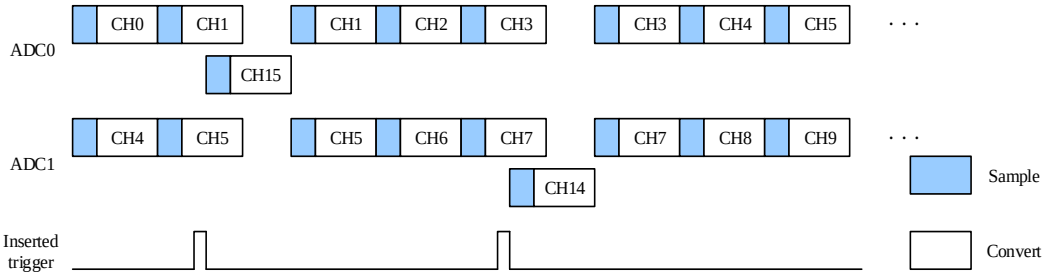
14.5.8. Combined regular parallel & trigger rotation mode

It is possible to interrupt regular group parallel conversion to start trigger rotation conversion of an inserted group. The behavior of an alternate trigger interrupt a regular parallel conversion shows in the *Figure 14-22. Regular parallel & trigger rotation mode*.

When the inserted event occurs, the inserted rotation conversion is immediately started. If regular conversion is already running, in order to ensure synchronization after the inserted conversion, the regular conversion of both (master/slave) ADCs is stopped and resumed synchronously at the end of the inserted conversion.

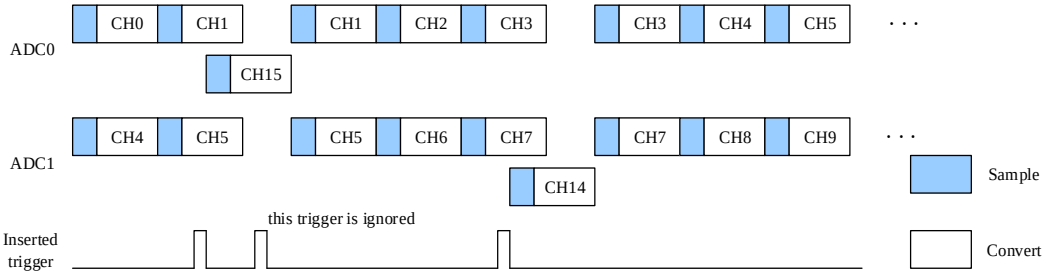
Note: In combined regular parallel + trigger rotation mode, the sampling time for the two ADCs should be configured the same.

Figure 14-22. Regular parallel & trigger rotation mode



If one inserted trigger occurs during an inserted conversion that has interrupted a regular conversion, it will be ignored. ***Figure 14-23. Trigger occurs during inserted conversion*** shows the case (the third trigger is ignored).

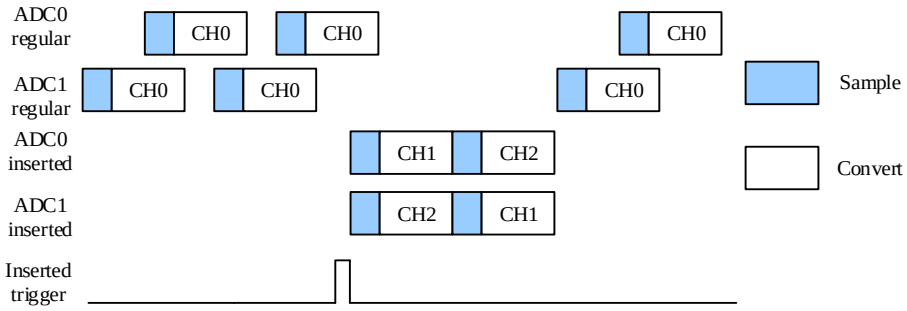
Figure 14-23. Trigger occurs during inserted conversion



14.5.9. Combined inserted parallel & follow-up mode

It is possible to interrupt a follow-up conversion (both fast and slow) with an inserted event. When the inserted trigger occurs, the follow-up conversion is interrupted and the inserted conversion starts, at the end of the inserted sequence the follow-up conversion is resumed. ***Figure 14-24. Follow-up single channel with inserted sequence CH1, CH2***shows the behavior of this mode.

Figure 14-24. Follow-up single channel with inserted sequence CH1, CH2



14.6. ADC interrupts

The interrupt can be produced on one of the events:

- End of conversion for regular and inserted groups

- The analog watchdog event

Separate interrupt enable bits are available for flexibility.

The interrupts of ADC0 and ADC1 are mapped into the same interrupt vector. The interrupts of ADC2 are mapped into a separateinterrupt vector.

14.7. Register definition

ADC0 start address: 0x4001 2400

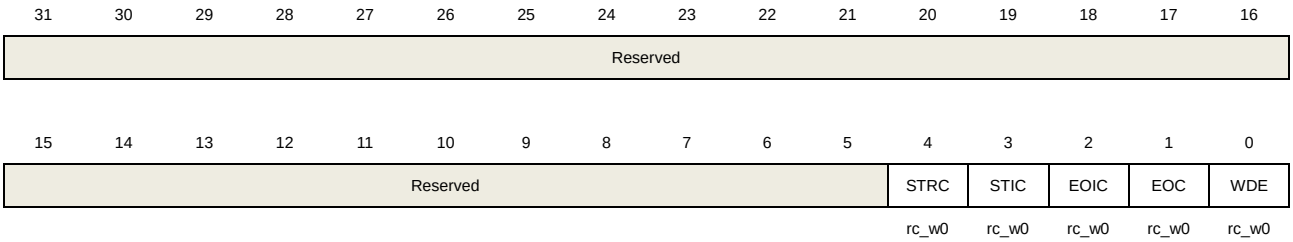
ADC1 start address: 0x4001 2800

ADC2 start address: 0x4001 3C00

14.7.1. Status register (ADC_STAT)

Address offset: 0x00
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:5	Reserved	Must be kept at reset value
4	STRC	Start flag of regular channel group 0: No regular channel group started 1: Regular channel group started Set by hardware when regular channel conversion starts. Cleared by software writing 0 to it.
3	STIC	Start flag of inserted channel group 0: No inserted channel group started 1: Inserted channel group started Set by hardware when inserted channel group conversion starts. Cleared by software writing 0 to it.
2	EOIC	End of inserted group conversion flag 0: No end of inserted group conversion 1: End of inserted group conversion Set by hardware at the end of all inserted group channel conversion. Cleared by software writing 0 to it.
1	EOC	End of group conversion flag 0: No end of group conversion 1: End of group conversion Set by hardware at the end of a regular or inserted group channel conversion.

Cleared by software writing 0 to it or by reading the ADC_RDATA register.

0	WDE	Analog watchdog event flag 0: No analog watchdog event 1: Analog watchdog event Set by hardware when the converted voltage crosses the values programmed in the ADC_WDLT and ADC_WDHT registers. Cleared by software writing 0 to it.

14.7.2. Control register 0 (ADC_CTL0)

Address offset: 0x04
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

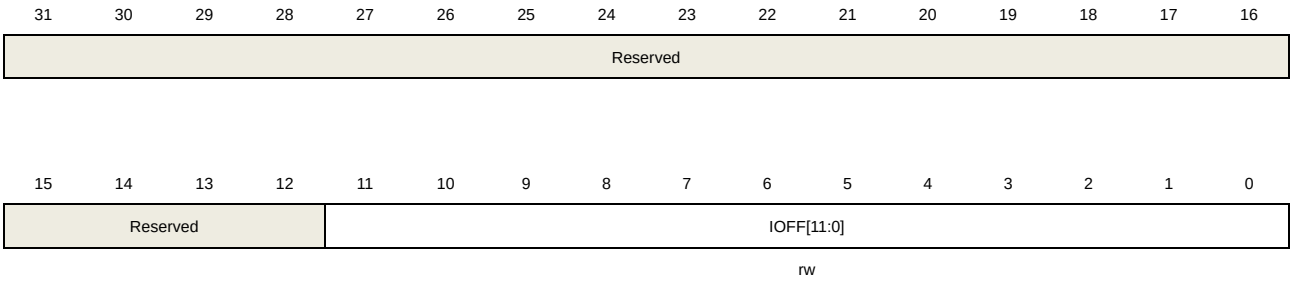
14.7.6. Inserted channel data offset register x (ADC_IOFFx) (x=0..3)

Address offset: 0x14-0x20

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



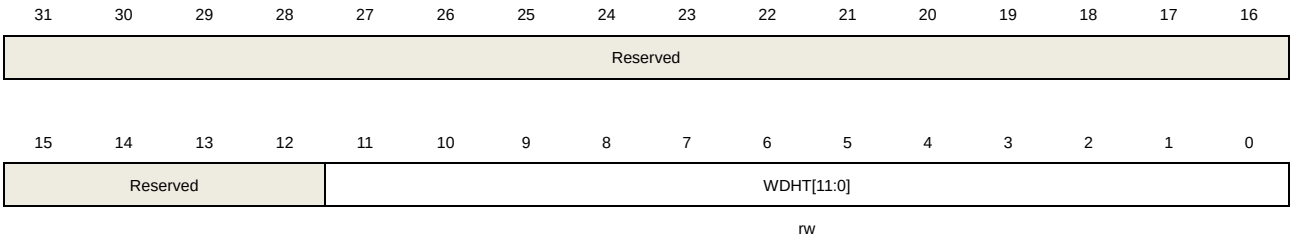
Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value

11:0	IOFF[11:0]	Data offset for inserted channel x These bits will be subtracted from the raw converted data when converting inserted channels. The conversion result can be read from in the ADC_IDATAx registers.

14.7.7. Watchdog high threshold register (ADC_WDHT)

Address offset: 0x24
Reset value: 0x0000 0FFF

This register has to be accessed by word(32-bit)

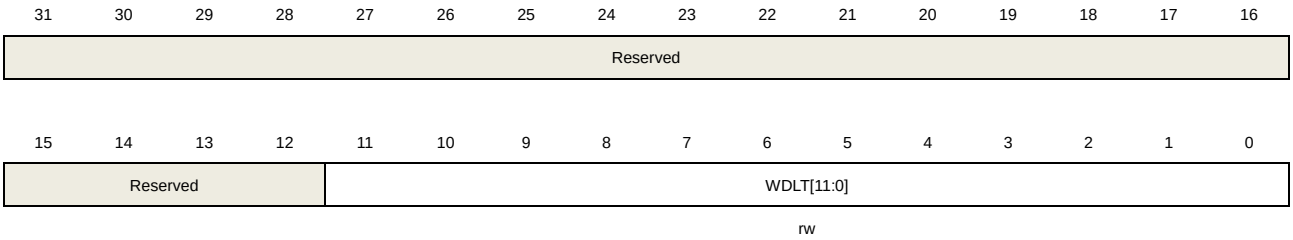


Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	WDHT[11:0]	Analog watchdog high threshold These bits define the high threshold for the analog watchdog.

14.7.8. Watchdog low threshold register (ADC_WDLT)

Address offset: 0x28
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



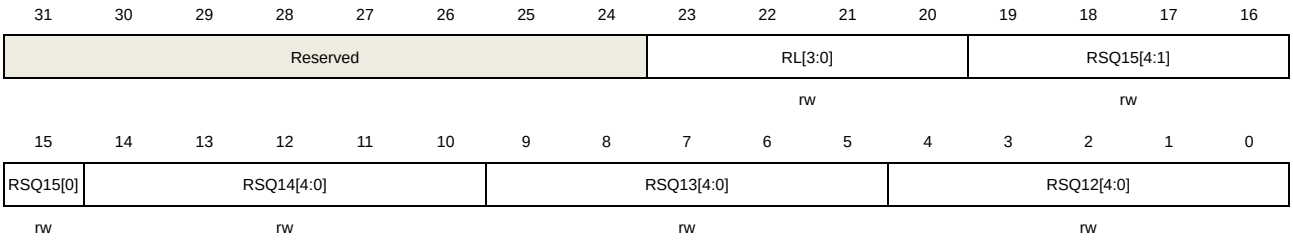
Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	WDLT[11:0]	Analog watchdog low threshold These bits define the low threshold for the analog watchdog.

14.7.9. Regular sequence register 0 (ADC_RSQ0)

Address offset: 0x2C

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:24	Reserved	Must be kept at reset value
23:20	RL[3:0]	Regular channel group length. The total number of conversion in regular group equals to RL[3:0]+1.

1	Reserved	Must be kept at reset value.
0	OVSEN	Oversampler Enable This bit is set and cleared by software. 0: Oversampler disabled 1: Oversampler enabled **Note:** Software is allowed to write this bit only when ADCON =0 (which ensures that no

conversion is ongoing).

15. Digital-to-analog converter (DAC)

15.1. Overview

The Digital-to-analog converter converts 12-bit digital data to a voltage on the external pins. The digital data can be configured in 8-bit or 12-bit mode, left-aligned or right-aligned mode. DMA can be used to update the digital data on external triggers. The output voltage can be optionally buffered for higher drive capability.

Two DACs can work independently or concurrently.

15.2. Characteristics

DAC's main features are as follows:

- 12-bit resolution. Left or right data alignment.
- DMA capability for each channel.
- Conversion update synchronously.
- Conversion trigged by external triggers.
- Configurable internal buffer.
- Input voltage reference, VREF+.
- Noise wave generation (LFSR noise mode and Triangle noise mode).
- Two DACs in concurrent mode.

Figure 15-1. DAC block diagram shows the block diagram of DAC and ***Table 15-1. DAC***

pins gives the pin description.

Figure 15-1. DAC block diagram

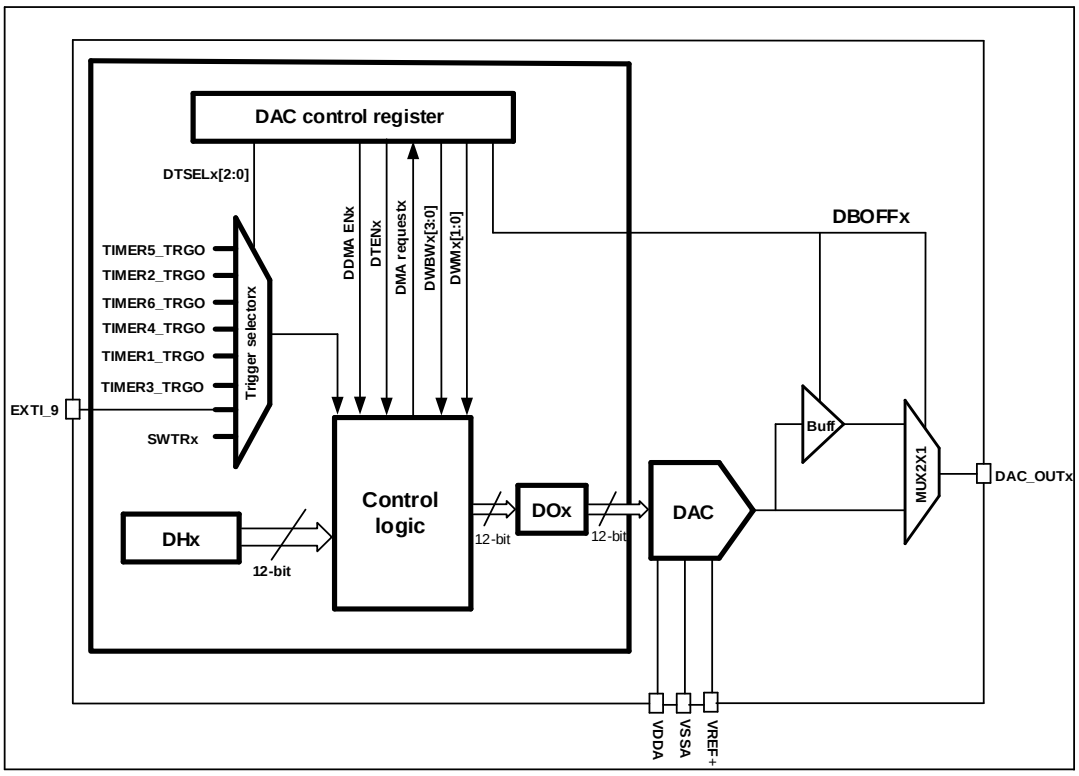

Table 15-1. DAC pins

Name	Description	Signal type
V_{DDA}	Analog power supply	Input, analog supply
V_{SSA}	Ground for analog power supply	Input, analog supply ground
V_{REF+}	Positive reference voltage for the DAC, 2.4 V ≤ V_{REF+} ≤ V_{DDA}	Input, analog positive reference
DAC_OUTx	DACx analog output	Analog output signal

The GPIO pins (PA4 for DAC0, PA5 for DAC1) should be configured to analog mode before enable the DAC module.

15.3. Function overview

15.3.1. DAC enable

The DACs can be powered on by setting the DENx bit in the DAC_CTL register. A t_{WAKEUP} time is needed to startup the analog DAC submodule.

15.3.2. DAC output buffer

For the concern of reducing output impedance, and driving external loads without an external operational amplifier, an output buffer is integrated inside each DAC module.

The output buffer, which is turned on by default, can be turned off by setting the DBOFFx bits in the DAC_CTL register.

15.3.3. DAC data configuration

The 12-bit DAC holding data (DACx_DH) can be configured by writing any one of the DACx_R12DH, DACx_L12DH and DACx_R8DH registers. When the data is loaded by DACx_R8DH register, only the MSB 8 bits are configurable, the LSB 4 bits are forced to 4'b0000.

15.3.4. DAC trigger

The DAC external trigger is enabled by setting the DTENx bits in the DAC_CTL register. The DAC external triggers are selected by the DTSELx bits in the DAC_CTL register.

Table 15-2. External triggers of DAC

DTSELx[2:0]	Trigger Source	Trigger Type
000	TIMER5_TRGO	Internal on-chip signal
001	TIMER2_TRGO	
010	TIMER6_TRGO	
011	TIMER4_TRGO	
100	TIMER1_TRGO	
101	TIMER3_TRGO	
110	EXTI_9	External signal
111	SWTRIG	Software trigger

The TIMERx_TRGO signals are generated from the timers, while the software trigger can be generated by setting the SWTRx bits in the DAC_SWT register.

15.3.5. DAC conversion

If the external trigger is enabled by setting the DTENx bit in DAC_CTL register, the DAC holding data is transferred to the DAC output data (DACx_DO) register at the selected trigger events. Otherwise, when the external trigger is disabled, the transfer is performed automatically.

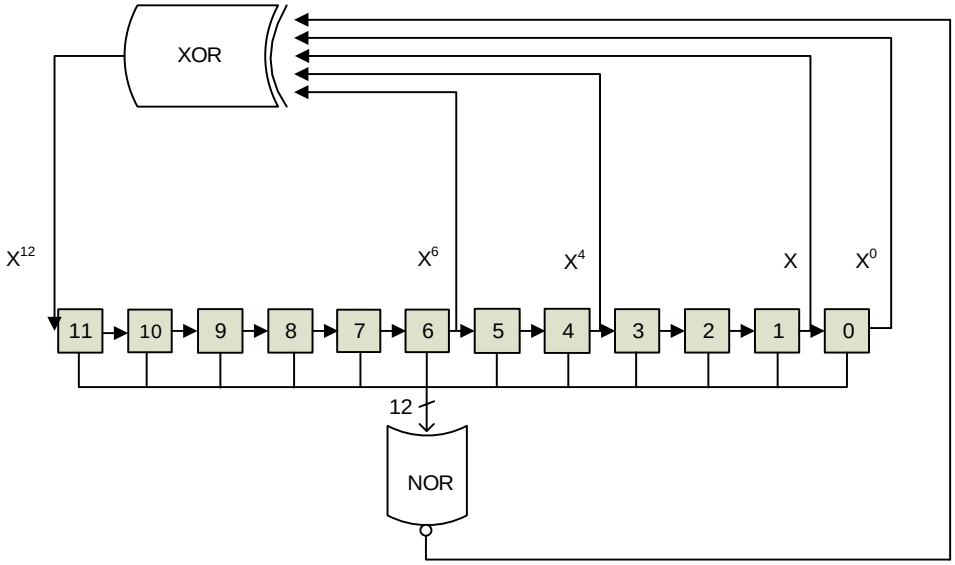
When the DAC holding data (DACx_DH) is loaded into the DACx_DO register, after the time $t_{SETTLING}$, the analog output is valid, and the value of $t_{SETTLING}$ is related to the power supply voltage and the analog output load.

15.3.6. DAC noise wave

There are two methods of adding noise wave to the DAC output data: LFSR noise wave and triangle wave. The noise wave mode can be selected by the DWMx bits in the DAC_CTL register. The amplitude of the noise can be configured by the DAC noise wave bit width (DWBWx) bits in the DAC_CTL register.

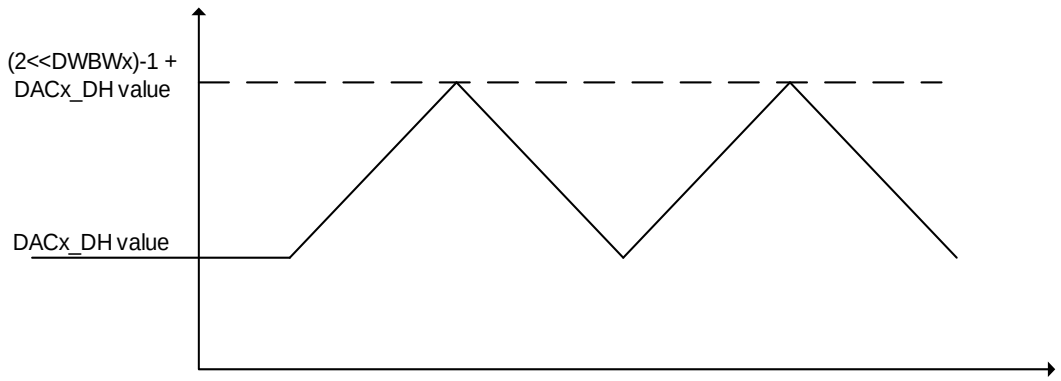
There is a Linear Feedback Shift Register (LFSR) in the DAC control logic. In the LFSR noise mode, the LFSR noise signal is added to the DACx_DH value. When the configured DAC noise wave bit width is less than 12, the noise signal equals to the LSB DWBWx bits of the LFSR register.

Figure 15-2. DAC LFSR algorithm



In the triangle noise mode, a triangle signal is added to the DACx_DH value. The minimum value of the triangle signal is 0, while the maximum value of the triangle signal is (2<<DWBWx)-1.

Figure 15-3. DAC triangle noise wave



15.3.7. DAC output voltage

The analog output voltages on the DAC pin are determined by the following equation:

$$DAC_{output}=V_{REF+}*DAC\_DO/4095 \quad (15\text{-}1)$$

The digital input is linearly converted to an analog output voltage, its range is 0 to V_{REF+}.

15.3.8. DMA request

When the external trigger is enabled, the DMA request is enabled by setting the DDMAENx bits of the DAC_CTL register. A DAC DMA request will be generated when an external hardware trigger (not a software trigger) occurs.

15.3.9. DAC concurrent conversion

When the two DACs work at the same time, for maximum bus bandwidth utilization in specific applications, two DACs can be configured in concurrent mode. In concurrent mode, the DACx_DH and DACx_DO value will be updated at the same time.

There are three concurrent registers that can be used to load the DACx_DH value: DACC_R8DH, DACC_R12DH and DACC_L12DH. You just need to access a unique register to realize driving both DACs at the same time.

When external trigger is enabled, both DTENx bits should be set. DTSEL0 and DTSEL1 bits should be configured with the same value.

When DMA is enabled, only one of the DDMAENx bits should be set.

The noise mode and noise bit width can be configured either the same or different, depending on the usage.

15.4. Register definition

DAC start address: 0x4000 7400

15.4.1. Control register (DAC_CTL)

Address offset: 0x00

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

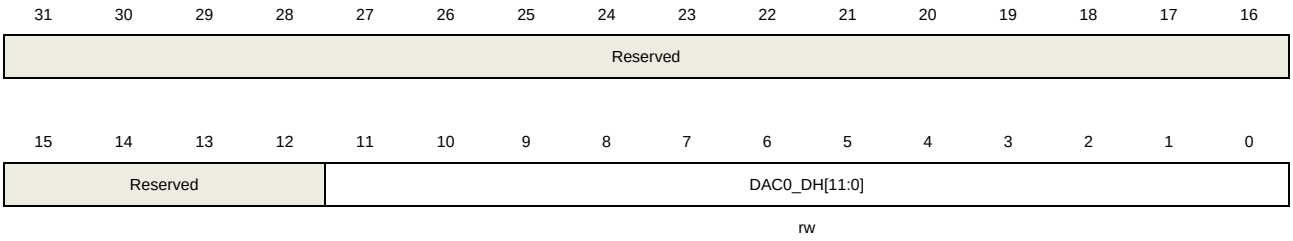
15.4.3. DAC0 12-bit right-aligned data holding register (DAC0_R12DH)

Address offset: 0x08
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

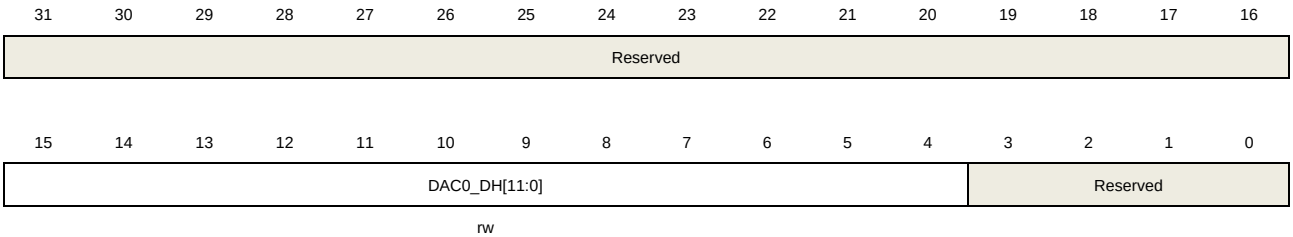


Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	DAC0_DH[11:0]	DAC0 12-bit right-aligned data These bits specify the data that is to be converted by DAC0.

15.4.4. DAC0 12-bit left-aligned data holding register (DAC0_L12DH)

Address offset: 0x0C
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



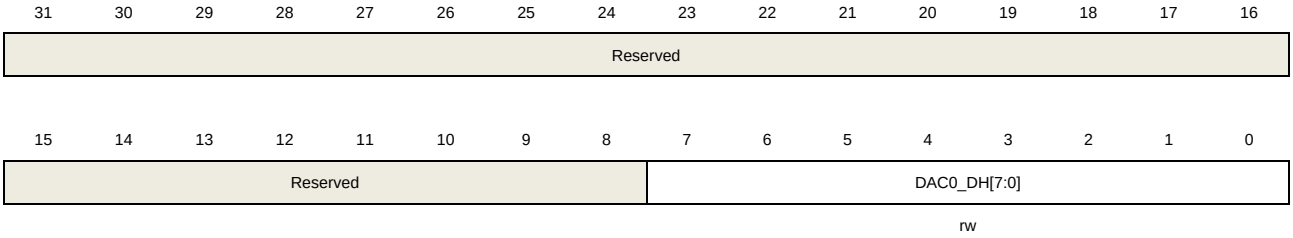
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:4	DAC0_DH[11:0]	DAC0 12-bit left-aligned data These bits specify the data that is to be converted by DAC0.
3:0	Reserved	Must be kept at reset value

15.4.5. DAC0 8-bit right-aligned data holding register (DAC0_R8DH)

Address offset: 0x10

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



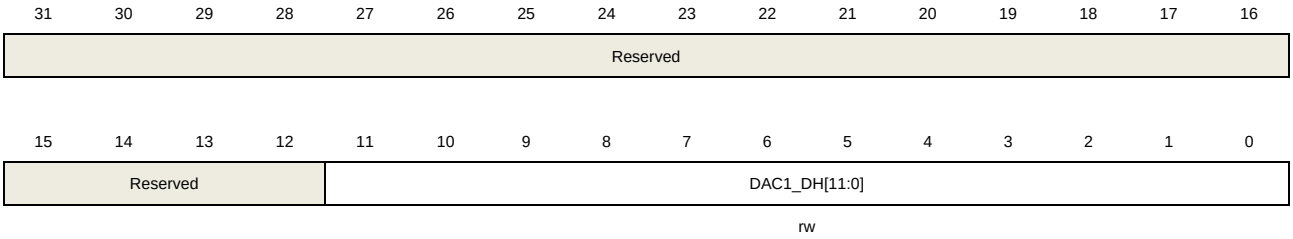
Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value
7:0	DAC0_DH[7:0]	DAC0 8-bit right-aligned data These bits specify the MSB 8 bits of the data that is to be converted by DAC0.

15.4.6. DAC1 12-bit right-aligned data holding register (DAC1_R12DH)

Address offset: 0x14

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	DAC1_DH[11:0]	DAC1 12-bit right-aligned data

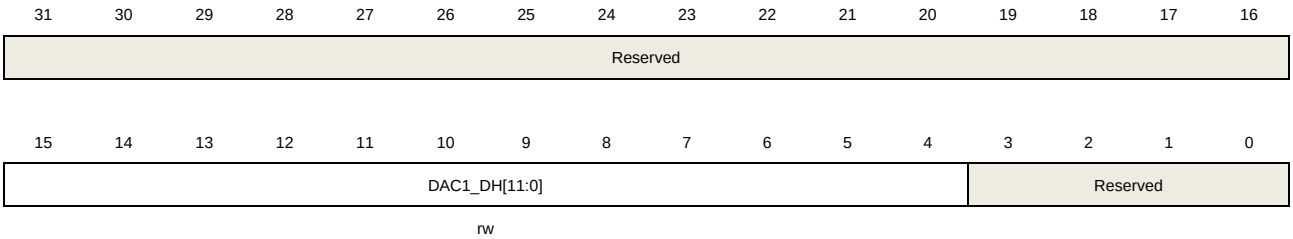
These bits specify the data that is to be converted by DAC1.

15.4.7. DAC1 12-bit left-aligned data holding register (DAC1_L12DH)

Address offset: 0x18

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



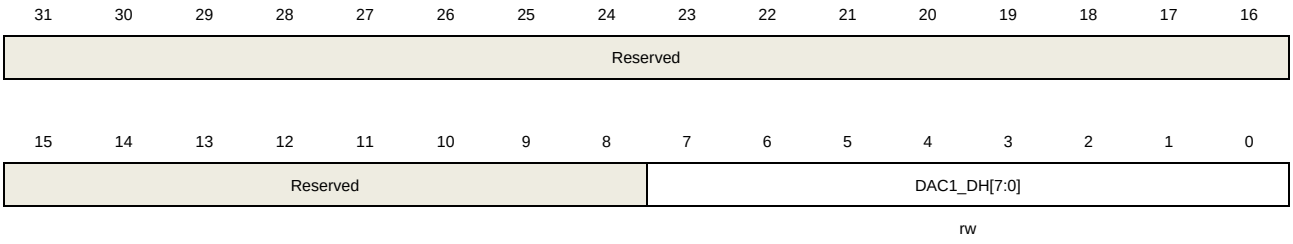
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:4	DAC1_DH[11:0]	DAC1 12-bit left-aligned data These bits specify the data that is to be converted by DAC1.
3:0	Reserved	Must be kept at reset value

15.4.8. DAC1 8-bit right-aligned data holding register (DAC1_R8DH)

Address offset: 0x1C

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



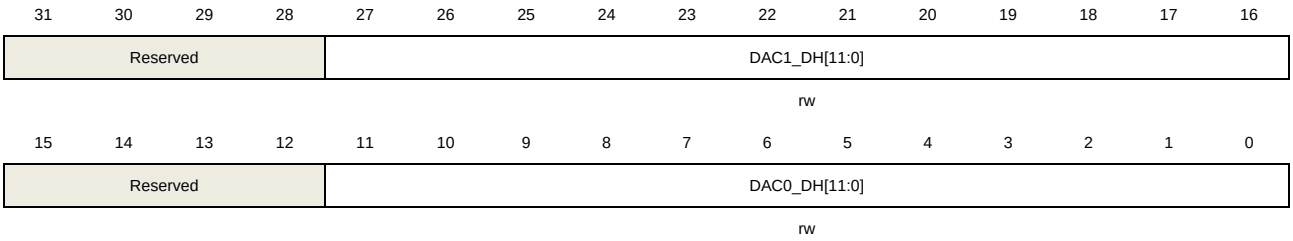
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
7:0	DAC1_DH[7:0]	DAC1 8-bit right-aligned data These bits specify the MSB bits of the data that is to be converted by DAC1.

15.4.9. DAC concurrent mode 12-bit right-aligned data holding register (DACC_R12DH)

Address offset: 0x20

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



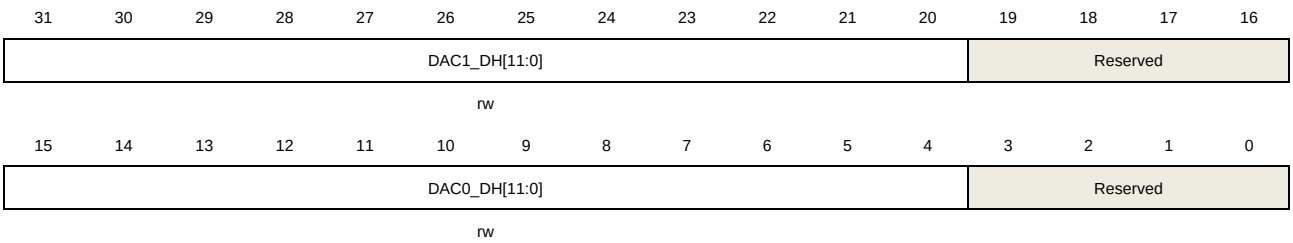
Bits	Fields	Descriptions
31:28	Reserved	Must be kept at reset value
27:16	DAC1_DH[11:0]	DAC1 12-bit right-aligned data These bits specify the data that is to be converted by DAC1.
15:12	Reserved	Must be kept at reset value
11:0	DAC0_DH[11:0]	DAC0 12-bit right-aligned data These bits specify the data that is to be converted by DAC0.

15.4.10. DAC concurrent mode 12-bit left-aligned data holding register (DACC_L12DH)

Address offset: 0x24

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



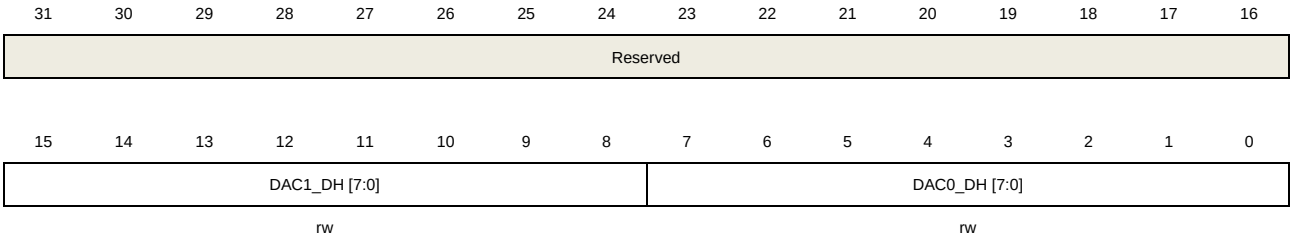
Bits	Fields	Descriptions
31:20	DAC1_DH[11:0]	DAC1 12-bit left-aligned data These bits specify the data that is to be converted by DAC1.

19:16	Reserved	Must be kept at reset value
15:4	DAC0_DH[11:0]	DAC0 12-bit left-aligned data These bits specify the data that is to be converted by DAC0.
3:0	Reserved	Must be kept at reset value

15.4.11. DAC concurrent mode 8-bit right-aligned data holding register (DACC_R8DH)

Address offset: 0x28
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

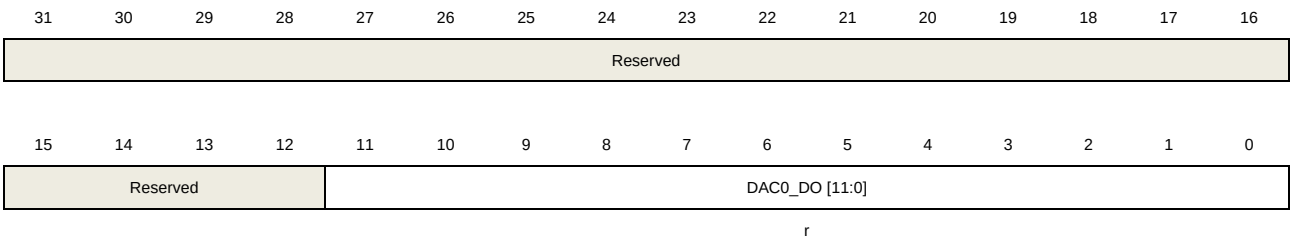


Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:8	DAC1_DH[7:0]	DAC1 8-bit right-aligned data These bits specify the MSB 8-bit of the data that is to be converted by DAC1.
7:0	DAC0_DH[7:0]	DAC0 8-bit right-aligned data These bits specify the MSB 8-bit of the data that is to be converted by DAC0.

15.4.12. DAC0 data output register (DAC0_DO)

Address offset: 0x2C
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



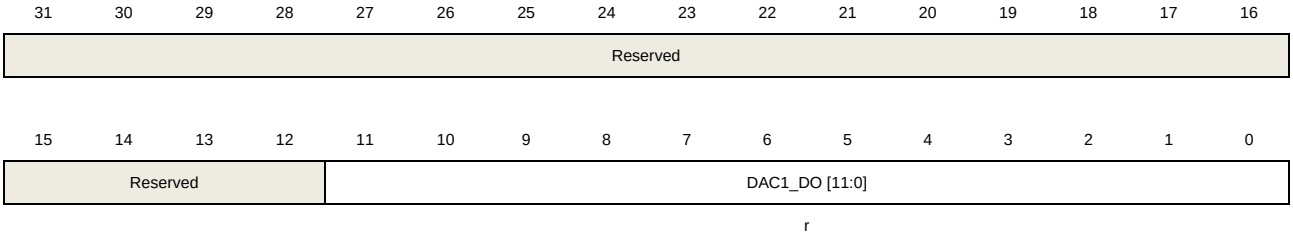
Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	DAC0_DO [11:0]	DAC0 data output These bits, which are read only, reflect the data that is being converted by DAC0.

15.4.13. DAC1 data output register (DAC1_DO)

Address offset: 0x30

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	DAC1_DO [11:0]	DAC1 data output These bits, which are read only, reflect the data that is being converted by DAC1.

16. Watchdog timer (WDGT)

The watchdog timer (WDGT) is a hardware timing circuitry that can be used to detect system failures due to software malfunctions. There are two watchdog timer peripherals in the chip: free watchdog timer (FWDGT) and window watchdog timer (WWDGT). They offer a combination of a high safety level, flexibility of use and timing accuracy. Both watchdog timers are offered to resolve malfunctions of software.

The watchdog timer will generate a reset (or an interrupt in window watchdog timer) when the internal counter reaches a given value. The watchdog timer counter can be stopped while the processor is in the debug mode.

16.1. Free watchdog timer (FWDGT)

16.1.1. Overview

The free watchdog timer (FWDGT) has free clock source (IRC40K). Thereupon the FWDGT can operate even if the main clock fails. It's suitable for the situation that requires an independent environment and lower timing accuracy.

The free watchdog timer causes a reset when the internal down counter reaches 0. The register write protection function in free watchdog can be enabled to prevent it from changing the configuration unexpectedly.

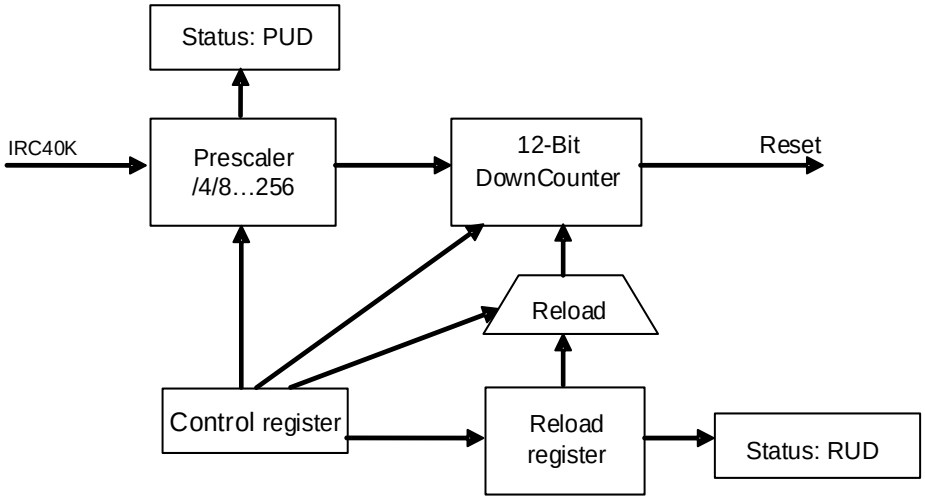
16.1.2. Charateristics

- Free-running 12-bit downcounter.
- Reset when the downcounter reaches 0, if the watchdog is enabled.
- Free clock source，FWDGT can operate even if the main clock fails such as in standby and Deep-sleep modes.
- Hardware free watchdog bit, automatically start the FWDGT at power on.
- FWDGT debug mode, the FWDGT can stop or continue to work in debug mode.

16.1.3. Function overview

The free watchdog consists of an 8-stage prescaler and a 12-bit down-counter. Refer to the figure below for the functional block of the free watchdog module.

Figure 16-1. Free watchdog block diagram



The free watchdog is enabled by writing the value 0xCCCC in the control register (FWDGT_CTL), and the counter starts counting down. When the counter reaches the value 0x000, a reset is generated.

The counter can be reloaded by writing the value 0xAAAA to the FWDGT_CTL register at anytime. The reload value comes from the FWDGT_RLD register. The software can prevent the watchdog reset by reloading the counter before the counter reaches the value 0x000.

The free watchdog can automatically start at power on when the hardware free watchdog bit in the device option bits is set. To avoid reset, the software should reload the counter before the counter reaches 0x000.

The FWDGT_PSC register and the FWDGT_RLD register are written protected. Before writing these registers, the software should write the value 0x5555 to the FWDGT_CTL register. These registers will be protected again by writing any other value to the FWDGT_CTL register. When an update operation of the prescaler register (FWDGT_PSC) or the reload value register (FWDGT_RLD) is on going, the status bits in the FWDGT_STAT register are set.

If the FWDGT_HOLD bit in DBG module is cleared, the FWDGT continues to work even the Cortex™-M3 core halted (Debug mode). While the FWDGT stops in Debug mode if the FWDGT_HOLD bit is set.

Table 16-1. Min/max FWDGT timeout period at 40 kHz (IRC40K)

Prescaler divider	PSC[2:0] bits	Min timeout (ms) RLD[11:0]=0x000	Max timeout (ms) RLD[11:0]=0xFFF
1/4	000	0.1	409.6
1/8	001	0.2	819.2
1/16	010	0.4	1638.4
1/32	011	0.8	3276.8
1/64	100	1.6	6553.6
1/128	101	3.2	13107.2

Prescaler divider	PSC[2:0] bits	Min timeout (ms) RLD[11:0]=0x000	Max timeout (ms) RLD[11:0]=0xFFF
1/256	110 or 111	6.4	26214.4

The FWDGT timeout can be more accurate by calibrating the IRC40K.

16.1.4. Register definition

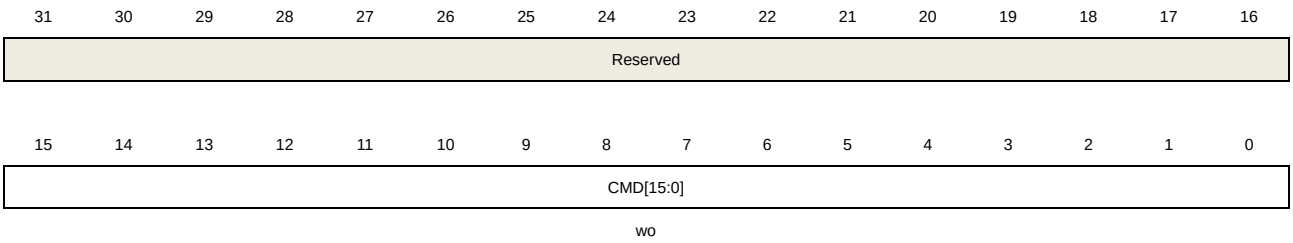
FWDGT start address: 0x4000 3000

Control register (FWDGT_CTL)

Address offset: 0x00

Reset value: 0x0000 0000

This register can be accessed by half-word (16-bit) or word (32-bit) access



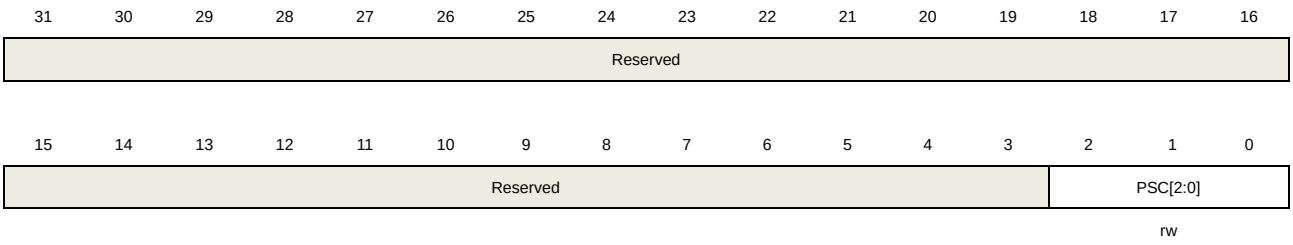
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	CMD[15:0]	Write only. Several different fuctions are realized by writing these bits with different values: 0x5555: Disable the FWDGT_PSC and FWDGT_RLD write protection 0xCCCC: Start the free watchdog counter. When the counter reduces to 0, the free watchdog generates a reset 0xAAAA: Reload the counter

Prescaler register (FWDGT_PSC)

Address offset: 0x04

Reset value: 0x0000 0000

This register can be accessed by half-word (16-bit) or word (32-bit) access



Bits	Fields	Descriptions
31:3	Reserved	Must be kept at reset value
2:0	PSC[2:0]	Free watchdog timer prescaler selection. Write 0x5555 in the FWDGT_CTL register

before writing these bits. During a write operation to this register, the PUD bit in the FWDGT_STAT register is set and the value read from this register is invalid.

000: 1/4 001: 1/8 010: 1/16

011: 1/32 100: 1/64 101: 1/128

110: 1/256 111: 1/256

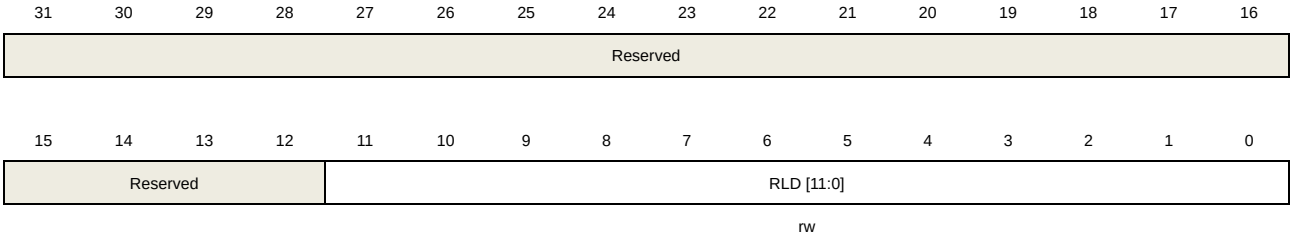
If several prescaler values are used by the application, it is mandatory to wait until PUD bit is reset before changing the prescaler value. However, after updating the prescaler value it is not necessary to wait until PUD is reset before continuing code execution.

Reload register (FWDGT_RLD)

Address offset: 0x08

Reset value: 0x0000 0FFF

This register can be accessed by half-word (16-bit) or word (32-bit) access



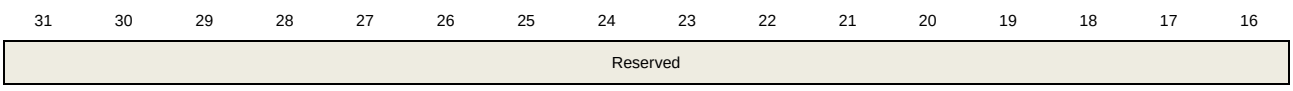
Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11:0	RLD[11:0]	Free watchdog timer counter reload value. Write 0xAAAA in the FWDGT_CTL register will reload the FWDGT counter with the RLD value. These bits are write-protected. Write 0x5555 in the FWDGT_CTL register before writing these bits. During a write operation to this register, the RUD bit in the FWDGT_STAT register is set and the value read from this register is invalid. If several reload values are used by the application, it is mandatory to wait until RUD bit is reset before changing the reload value. However, after updating the reload value it is not necessary to wait until RUD is reset before continuing code execution.

Status register (FWDGT_STAT)

Address offset: 0x0C

Reset value: 0x0000 0000

This register can be accessed by half-word(16-bit) or word(32-bit) access



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														RUD	PUD
														ro	ro

Bits	Fields	Descriptions
31:2	Reserved	Must be kept at reset value
1	RUD	Free watchdog timer counter reload value update During a write operation to FWDGT_RLD register, this bit is set and the value read from FWDGT_RLD register is invalid. This bit is reset by hardware after the update operation of FWDGT_RLD register.
0	PUD	Free watchdog timer prescaler value update During a write operation to FWDGT_PSC register, this bit is set and the value read from FWDGT_PSC register is invalid. This bit is reset by hardware after the update operation of FWDGT_PSC register.

16.2. Window watchdog timer (WWDGT)

16.2.1. Overview

The window watchdog timer (WWDGT) is used to detect system failures due to software malfunctions. After the window watchdog timer starts, the value of downcounter reduces progressively. The watchdog timer causes a reset when the counter reached 0x3F (the CNT[6] bit becomes cleared). The watchdog timer also causes a reset if the counter is refreshed before the counter reached the window register value. So the software should refresh the counter in a limited window. The window watchdog timer generates an early wakeup status flag when the counter reaches 0x40 or refreshes before the counter reaches the window value. Interrupt occurs if it is enabled.

The window watchdog timer clock is prescaled from the APB1 clock. The window watchdog timer is suitable for the situation that requires an accurate timing.

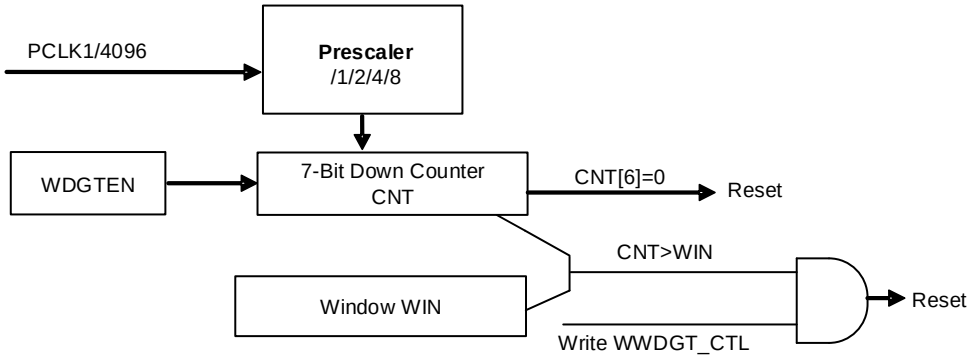
16.2.2. Charateristics

- Programmable free-running 7-bit downcounter.
- Generate reset in two conditions when WWDGT is enabled:
  - Reset when the counter reached 0x3F.
  - The counter is refreshed when the value of the counter is greater than the window register value.
- Early wakeup interrupt (EWI): if the watchdog is started and the interrupt is enabled, the interrupt occurs when the counter reaches 0x40 or refreshes before it reaches the window value.
- WWDGT debug mode, the WWDGT can stop or continue to work in debug mode.

16.2.3. Function overview

If the window watchdog timer is enabled (set the WDGTEN bit in the WWDGT_CTL), the watchdog timer cause a reset when the counter reaches 0x3F (the CNT[6] bit becomes cleared), or when the counter is refreshed before the counter reaches the window register value.

Figure 16-2. Window watchdog timer block diagram



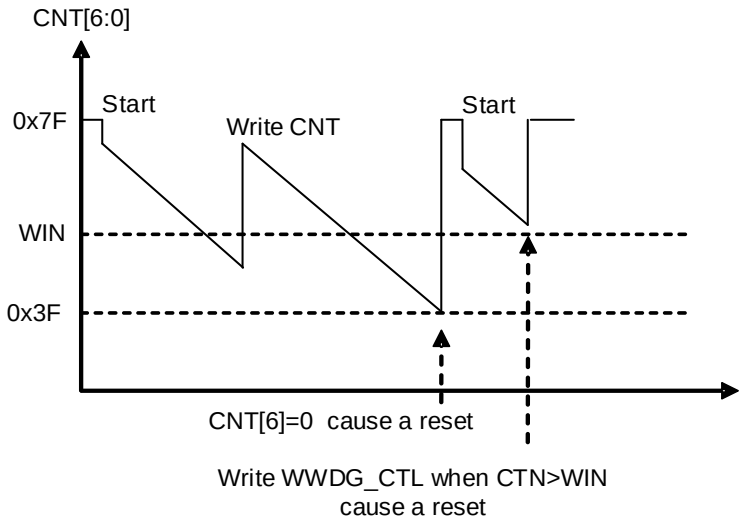
The watchdog is always disabled after power on reset. The software starts the watchdog by setting the WDGTEN bit in the WWDGT_CTL register. Whenever window watchdog timer is enabled, the counter counts down all the time, the configured value of the counter should be greater than 0x3F, it implies that the CNT[6] bit should be set. The CNT[5:0] determine the maximum time interval of two reloading. The countdown speed depends on the APB1 clock and the prescaler (PSC[1:0] bits in the WWDGT_CFG register).

The WIN[6:0] bits in the configuration register (WWDGT_CFG) specifies the window value. The software can prevent the reset event by reloading the downcounter when counter value is less than the window value and greater than 0x3F, otherwise the watchdog causes a reset.

The early wakeup interrupt (EWI) is enabled by setting the EWIE bit in the WWDGT_CFG register, and the interrupt is generated when the counter reaches 0x40 or the counter is refreshed before it reaches the window value. The software can do something such as communication or data logging in the interrupt service routine (ISR) in order to analyse the reason of software malfunctions or save the important data before resetting the device. Moreover the software can reload the counter in ISR to manage a software system check and so on. In this case, the WWDGT will never generate a WWDGT reset but can be used for other things.

The EWI interrupt is cleared by writing '0' to the EWIF bit in the WWDGT_STAT register.

Figure 16-3. Window watchdog timing diagram



Calculate the WWDGT timeout by using the formula below.

$$t_{WWDGT}=t_{PCLK1} \times 4096 \times 2^{PSC} \times (CNT[5:0]+1) \quad (ms) \qquad (16\text{-}1)$$

where:

t_{WWDGT}: WWDGT timeout

t_{PCLK1}: APB1 clock period measured in ms

Refer to the table below for the minimum and maximum values of the t_{WWDGT}.

Table 16-2. Min/max timeout value at 60 MHz (f_{PCLK1})

Prescaler divider	PSC[1:0]	Min timeout value CNT[6:0] =0x40	Max timeout value CNT[6:0]=0x7F
1/1	00	68.2 µs	4.3ms
1/2	01	136.4 µs	8.6 ms
1/4	10	272.8µs	17.2 ms
1/8	11	545.6 µs	34.4 ms

If the WWDGT_HOLD bit in DBG module is cleared, the WWDGT continues to work even the Cortex™-M3 core halted (Debug mode). While the WWDGT_HOLD bit is set, the WWDGT stops in Debug mode.

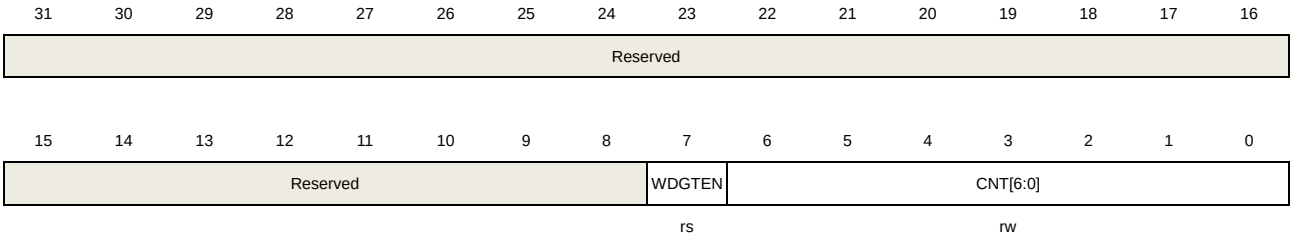
16.2.4. Register definition

WWDGT start address:0x4000 2C00

Control register (WWDGT_CTL)

Address offset: 0x00
Reset value: 0x0000 007F

This register can be accessed by half-word (16-bit) or word (32-bit)

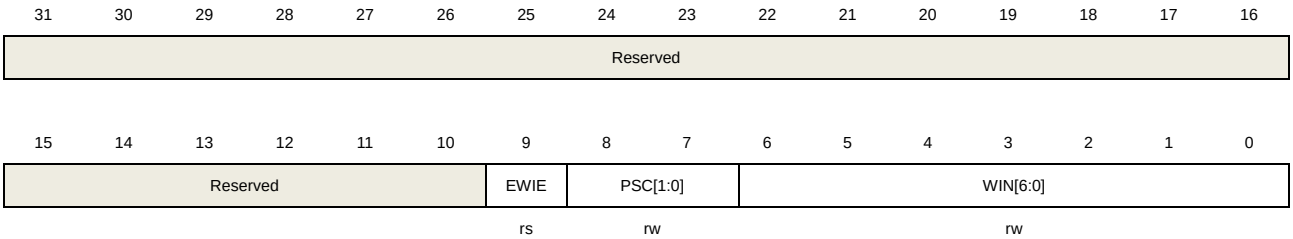


Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value.
7	WDGTEN	Start the window watchdog timer. Cleared by a hardware reset. Writing 0 has no effect. 0: Window watchdog timer disabled 1: Window watchdog timer enabled
6:0	CNT[6:0]	The value of the watchdog timer counter. A reset occurs when the value of this counter decreases from 0x40 to 0x3F. When the value of this counter is greater than the window value, writing this counter also causes a reset.

Configuration register (WWDGT_CFG)

Address offset: 0x04
Reset value: 0x0000 007F

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
31:10	Reserved	Must be kept at reset value.
9	EWIE	Early wakeup interrupt enable. An interrupt occurs when the counter reaches 0x40 or the

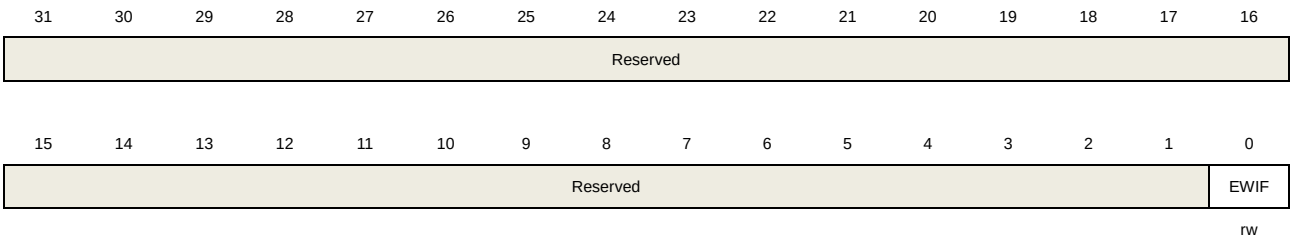
		counter is refreshed before it reaches the window value if the bit is set. It can be cleared by a hardware reset or by a RCU WWDGT software reset. A write operation of '0' has no effect.
8:7	PSC[1:0]	Prescaler. The time base of the watchdog timer counter 00: (PCLK1 / 4096) / 1 01: (PCLK1 / 4096) / 2 10: (PCLK1 / 4096) / 4 11: (PCLK1 / 4096) / 8
6:0	WIN[6:0]	The Window value. A reset occurs if the watchdog counter (CNT bits in WWDGT_CTL) is written when the value of the watchdog counter is greater than the Window value.

Status register (WWDGT_STAT)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
31:1	Reserved	Must be kept at reset value.
0	EWIF	Early wakeup interrupt flag. When the counter reaches 0x40 or refreshes before it reaches the window value, this bit is set by hardware even the interrupt is not enabled (EWIE in WWDGT_CFG is cleared). This bit is cleared by writing 0 to it. There is no effect when writing 1 to it.

17. Real-time Clock(RTC)

17.1. Overview

The RTC is usually used as a clock-calendar. The RTC circuits are located in two power supply domains, backup domain and VDD domain. The ones in the Backup Domain consist of a 32-bit up-counter, an alarm, a prescaler, a divider and the RTC clock configuration register. It means the RTC settings and time are kept when the device resets or wakes up from Standby mode. While the circuits in the VDD domain only include the APB interface 、CTL and INTEN register. In the following sections, the details of the RTC function will be described.

17.2. Characteristics

- 32-bit programmable counter for counting elapsed time
  Programmable prescaler: Max division factor is up to 2^{20}
- Separate clock domains:
  A) PCLK1 clock domain
  B) RTC clock domain (this clock must be at least 4 times slower than the PCLK1 clock)
- RTC clock source:
  A) HXTAL clock divided by 128
  B) LXTAL oscillator clock
  C) IRC40K oscillator clock
- Maskable interrupt source:
  A) Alarm interrupt
  B) Second interrupt
  C) Overflow interrupt

17.3. Function overview

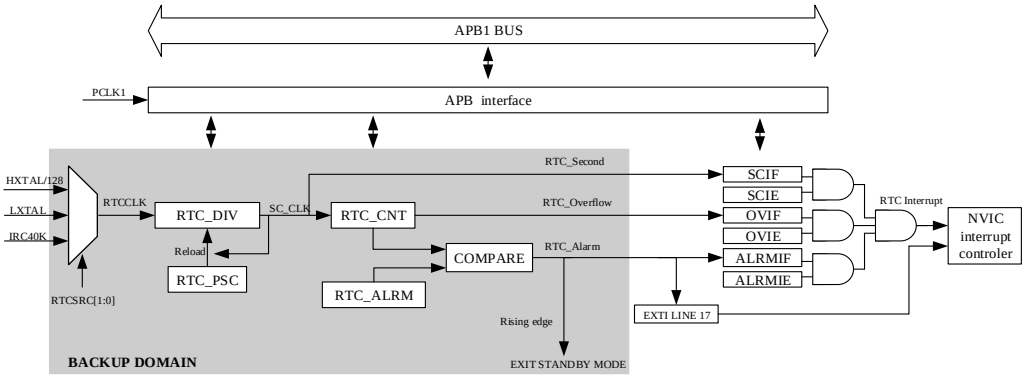
The RTC circuits consist of two major units: APB interface located in PCLK1 clock domain and RTC core located in RTC clock domain.

APB Interface is connected with the APB1 bus. It includes a set of registers, can be accessed by APB1 bus.

RTC core includes two major blocks. One is the RTC prescaler block, which generates the RTC time base clock SC_CLK. RTC prescaler block includes a 20-bit programmable divider (RTC prescaler) which can lead that SC_CLK is divided from RTC source clock. If second interrupt is enabled in the RTC_INTEN register, the RTC will generate an interrupt at every

SC_CLK rising edge. Another block is a 32-bit programmable counter, which can be initialized with the value of current system time. If alarm interrupt is enabled in the RTC_INTEN register, the RTC will generate an alarm interrupt when the system time equals to the alarm time (stored in the RTC_ALRMH/L register),

Figure 17-1. Block diagram of RTC



17.3.1. RTC reset

The APB interface and the RTC_INTEN register are reset by system reset. The RTC core (prescaler, divider, counter and alarm) is reset only by a backup domain reset.

Steps to enable access to the backup registers and the RTC after reset are as follows:

1. Set the PMUEN and BKPIEN bits in the RCU_APB1EN register to enable the power and backup interface clocks.

2. Enable access to the backup registers and RTC by setting the BKPWEN bit in the (PMU_CTL).

17.3.2. RTC reading

The APB interface and RTC core are located in two different power supply domains.

In the RTC core, only counter and divider registers are readable registers. And the values in the two registers and the RTC flags are internally updated at each rising edge of the RTC clock, which is resynchronized by the APB1 clock.

When the APB interface is immediately enabled from a disable state, the read operation is not recommended because the first internal update of the registers has not finished. That means, when a system reset, power reset, waking up from Standby mode or Deep-sleep mode occurs, the APB interface was in disabled state, but the RTC core has been kept running. In these cases, the correct read operation should first clear the RSYNF bit in the RTC _CTL register and wait for it to be set by hardware. While WFI and WFE have no effects on the RTC APB interface.

17.3.3. RTC configuration

The RTC_PSC, RTC_CNT and RTC_ALRM registers in the RTC core are writable. These registers' value can be set only when the peripheral enter configuration mode. And the CMF bit in the RTC_CTL register is used to indicate the configuration mode status. The write operation executes when the peripheral exit configuration mode, and it takes at least three RTCCLK cycles to complete. The value of the LWOFF bit in the RTC_CTL register sets to '1', if the write operation finished. The new write operation should wait for the previous one finished.

The configuration steps are as follows:
A) Wait until the value of LWOFF bit in the RTC_CTL register sets to '1';
B) Enter Configuration mode by setting the CMF bit in the RTC_CTL register;
C) Write to the RTC registers;
D) Exit Configuration mode by clearing the CMF bit in the RTC_CTL register;
E) Wait until the value of LWOFF bit in the RTC_CTL register sets to '1'.

17.3.4. RTC flag assertion

Before the update of the RTC Counter, the RTC second interrupt flag (SCIF) is asserted on the last RTCCLK cycle.

Before the counter which is equal to the RTC Alarm value which stored in the Alarm register, increases by one, the RTC Alarm interrupt flag (ALRMIF) is asserted on the last RTCCLK cycle.

Before the counter equals to 0x0, the RTC Overflow interrupt flag (OVIF) is asserted on the last RTCCLK cycle.

The RTC Alarm write operation and Second interrupt flag must be synchronized by using either of the following sequences:

- Use the RTC alarm interrupt and update the RTC Alarm and/or RTC Counter registers inside the RTC interrupt routine;
- Update the RTC Alarm and/or the RTC Counter registers after the SCIF bit to be set in the RTC Control register.

Figure 17-2. RTC second and alarm waveform example (RTC_PSC = 3, RTC_ALRM = 2)

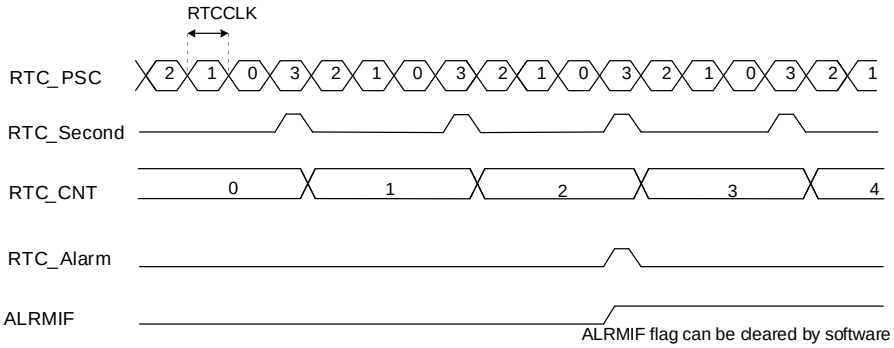


Figure 17-3. RTC second and overflow waveform example (RTC_PSC= 3)

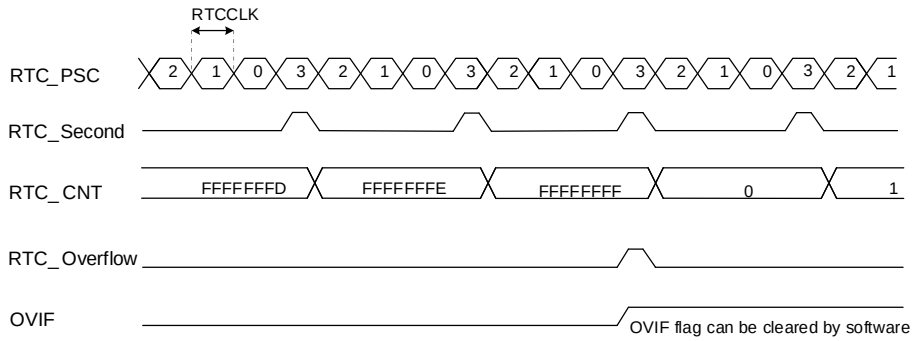

17.4. Register definition

RTC start address: 0x4000 2800

17.4.1. RTC interrupt enable register(RTC_INTEN)

Address offset: 0x00

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

18.1. Advanced timer (TIMERx, x=0, 7)

18.1.1. Overview

The advanced timer module (Timer0 & Timer7) is a four-channel timer that supports both input capture and output compare. They can generate PWM signals to control motor or be used for power management applications. The advanced timer has a 16-bit counter that can be used as an unsigned counter.

In addition, the advanced timers can be programmed and be used for counting, their external events can be used to drive other timers.

Timer also includes a dead-time Insertion module which issuitable for motor control applications.

Timer and timer are completely independent with each other, but they may be synchronized to provide a larger timer with their counters incrementing in unison.

18.1.2. Characteristics

- Total channel num: 4.
- Counter width: 16 bit.
- Source of counter clock is selectable:
  internal clock, internal trigger, external input, external trigger.
- Multiple counter modes: count up, count down, count up/down.
- Quadrature Decoder: used to track motion and determine both rotation direction and position.
- Hall sensor: for 3-phase motor control.
- Programmable prescaler: 16 bit.The factor can be changed on the go.
- Each channel is user-configurable:
  input capture mode, output compare mode, programmable PWM mode, single pulse mode
- Programmable dead time insertion.
- Auto reload function.
- Programmable counter repetition function.
- Break input.
- Interrupt output or DMA request on: update, trigger event, compare/capture event, and break input.

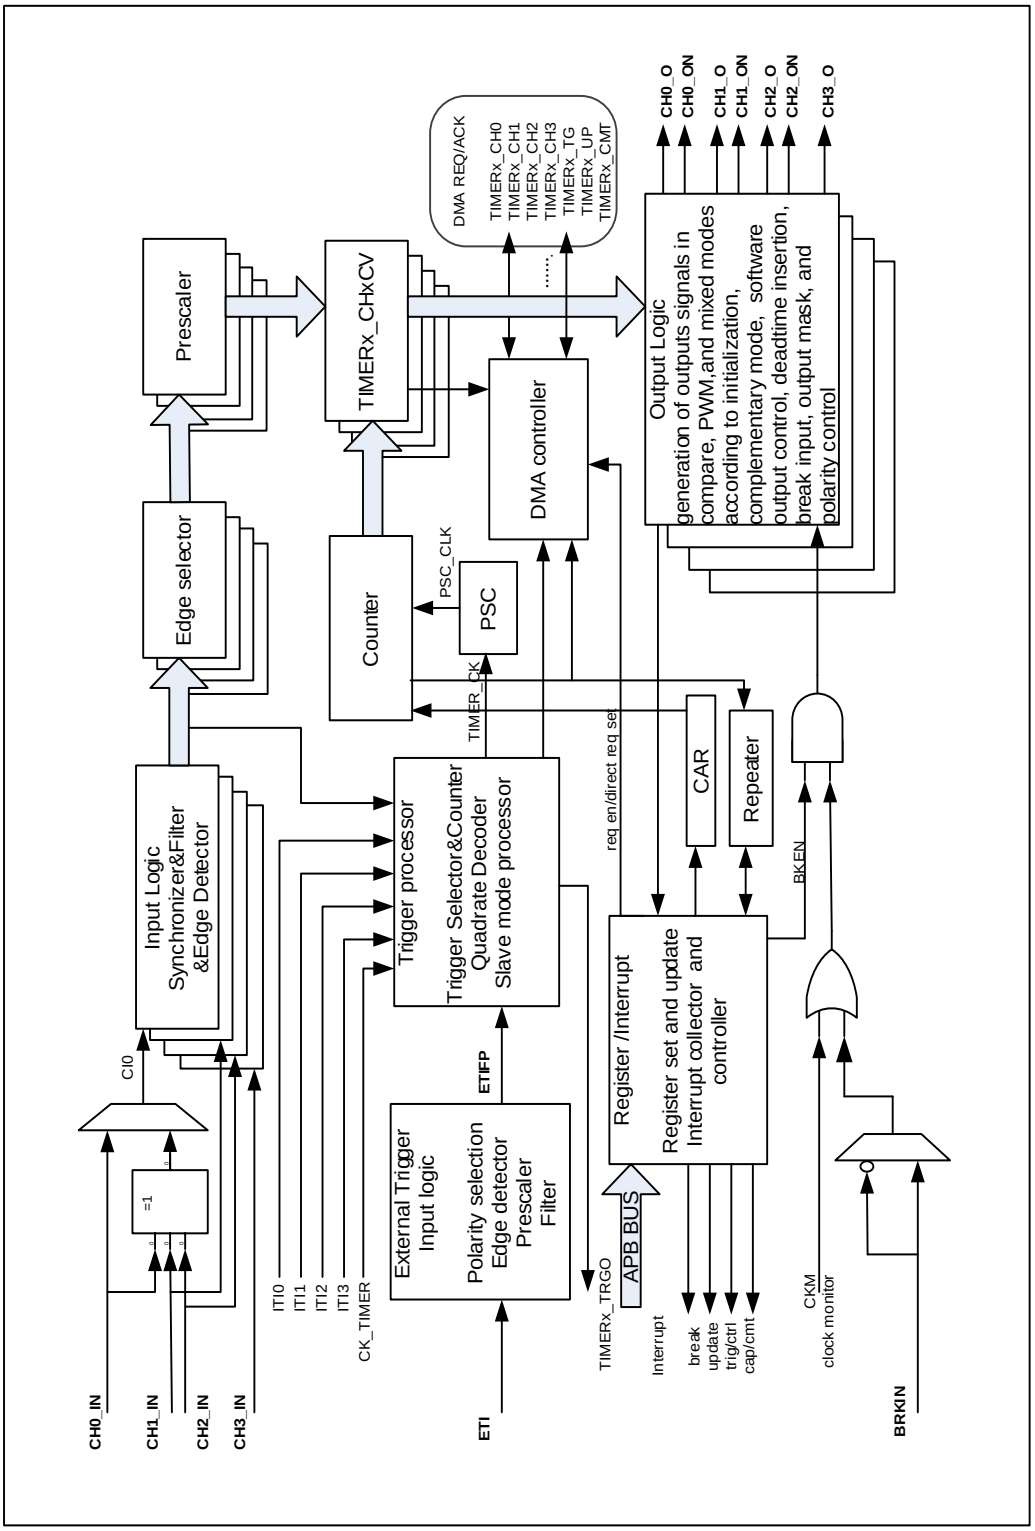
- Daisy chaining of timer modules allows a single timer to initiate multiple timers.
- Timer synchronization allows selected timers to start counting on the same clock cycle.
- Timer Master/Slave mode controller.

18.1.3. Block diagram

Figure 18-1. Advanced timer block diagram provides details of the internal configuration of

the advanced timer.

Figure 18-1. Advanced timer block diagram



18.1.4. Function overview

Clock selection

The advanced timer has the capability of being clocked by either the TIMER_CK or an alternate clock source controlled by SMC (TIMERx_SMCFG bit [2:0]).

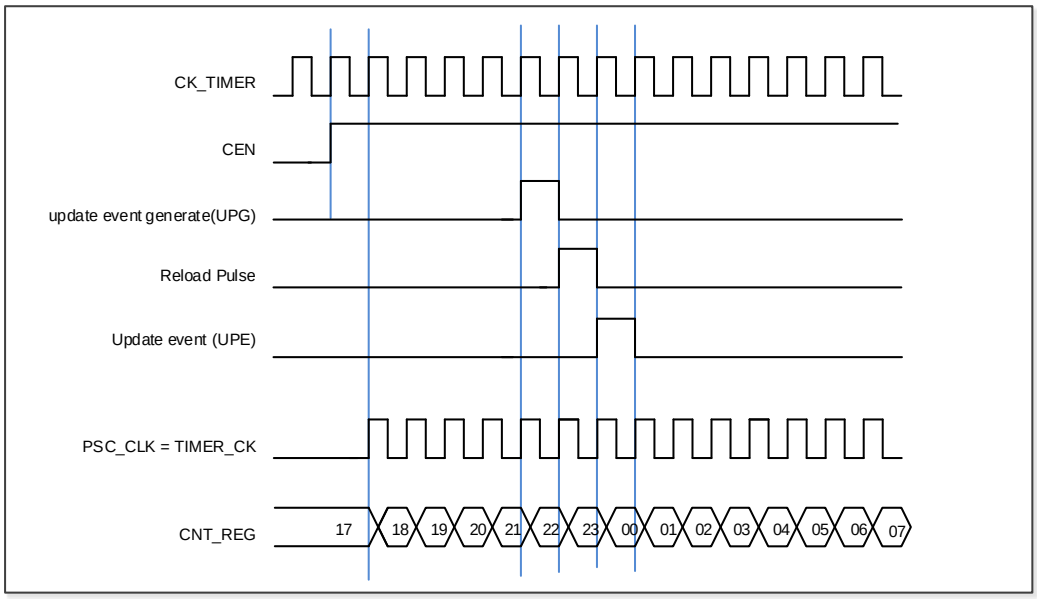
- SMC [2:0] == 3'b000. Internal clock CK_TIMER is selected as timer clock source which is from module RCU.

The default clock source is the CK_TIMER for driving the counter prescaler when the slave mode is disabled (SMC [2:0] == 3'b000). When the CEN is set, the CK_TIMER will be divided by PSC value to generate PSC_CLK.

In this mode, the TIMER_CK, which drives counter's prescaler to count, is equal to CK_TIMER which is from RCU.

If the slave mode controller is enabled by setting SMC [2:0] in the TIMERx_SMCFG register to an available value including 0x1, 0x2, 0x3 and 0x7, the prescaler is clocked by other clock sources selected by the TRGS [2:0] in the TIMERx_SMCFG register, details as follows. When the slave mode selection bits SMC [2:0] are set to 0x4, 0x5 or 0x6, the internal clock TIMER_CK is the counter prescaler driving clock source.

Figure 18-2. Normal mode, internal clock divided by 1



- SMC [2:0] == 3'b111 (external clock mode 0). External input pin is selected as timer clock source

The TIMER_CK, which drives counter's prescaler to count, can be triggered by the event of rising or falling edge on the external pin TIMERx_CH0/TIMERx_CH1. This mode can be selected by setting SMC [2:0] to 0x7 and the TRGS [2:0] to 0x4, 0x5 or 0x6.

And, the counter prescaler can also be driven by rising edge on the internal trigger input pin ITI0/1/2/3. This mode can be selected by setting SMC [2:0] to 0x7 and the TRGS [2:0] to 0x0, 0x1, 0x2 or 0x3.

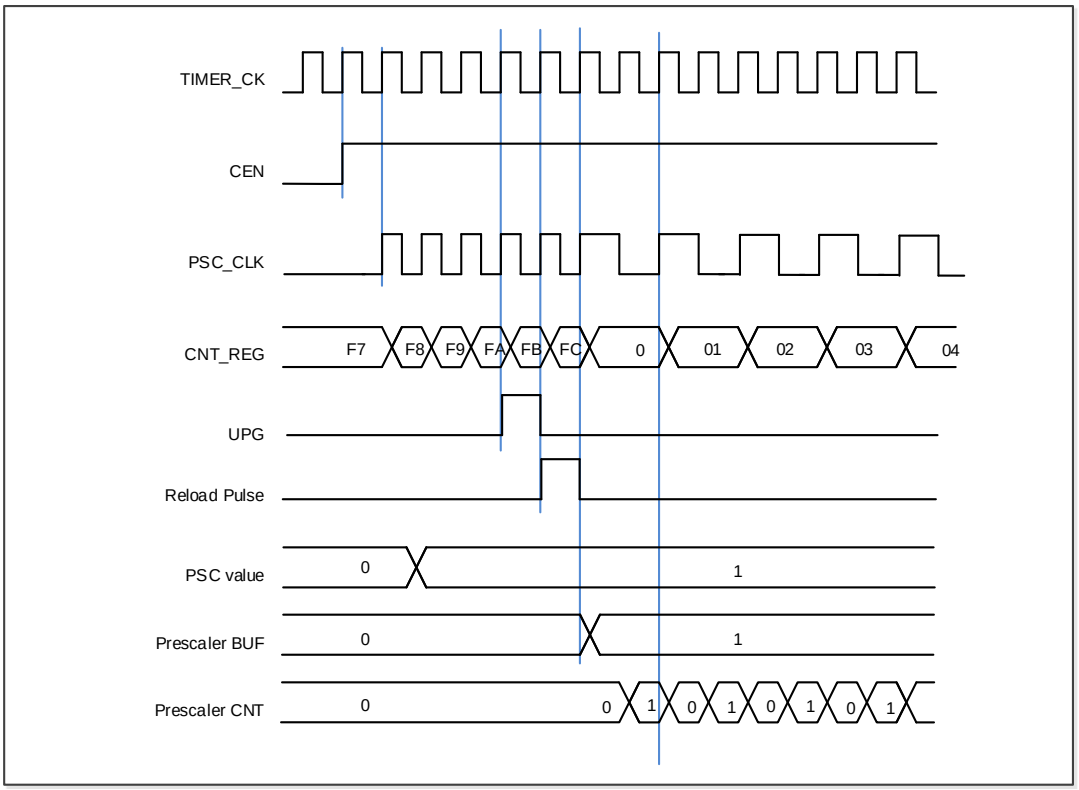
- SMC1== 1'b1 (external clock mode 1). External input is selected as timer clock source (ETI)

The TIMER_CK, which drives counter's prescaler to count, can be triggered by the event of rising or falling edge on the external pin ETI. This mode can be selected by setting the SMC1 bit in the TIMERx_SMCFG register to 1. The other way to select the ETI signal as the clock source is to set the SMC [2:0] to 0x7 and the TRGS [2:0] to 0x7 respectively. Note that the ETI signal is derived from the ETI pin sampled by a digital filter. When the ETI signal is selected as clock source, the trigger controller including the edge detection circuitry will generate a clock pulse on each rising edge of ETI signal to provide clock to the counter prescaler.

Prescaler

The prescaler can divide the timer clock (TIMER_CK) to a counter clock (PSC_CLK) by any factor between 1 and 65536. It is controlled by prescaler register (TIMERx_PSC) which can be changed on the go but is taken into account at the next update event.

Figure 18-3. Counter timing diagram with prescaler division change from 1 to 2 (PSC value change from 0 to 1)



Up counting mode

In this mode, the counter counts up continuously from 0 to the counter-reload value, which is defined in the TIMERx_CAR register, in a count-up direction. Once the counter reaches the counter reload value, the counter restarts from 0. If the repetition counter is set, the update events will be generated after (TIMERx_CREP+1) times of overflow. Otherwise the update event is generated each time when overflows. The counting direction bit DIR in the TIMERx_CTL0 register should be set to 0 for the up counting mode.

Whenever, if the update event software trigger is enabled by setting the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to 0 and generates an update event.

If set the UPDIS bit in TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior for different clock prescaler factor when TIMERx_CAR=0x63.

Figure 18-4. Up-counter timechart, PSC=0/1

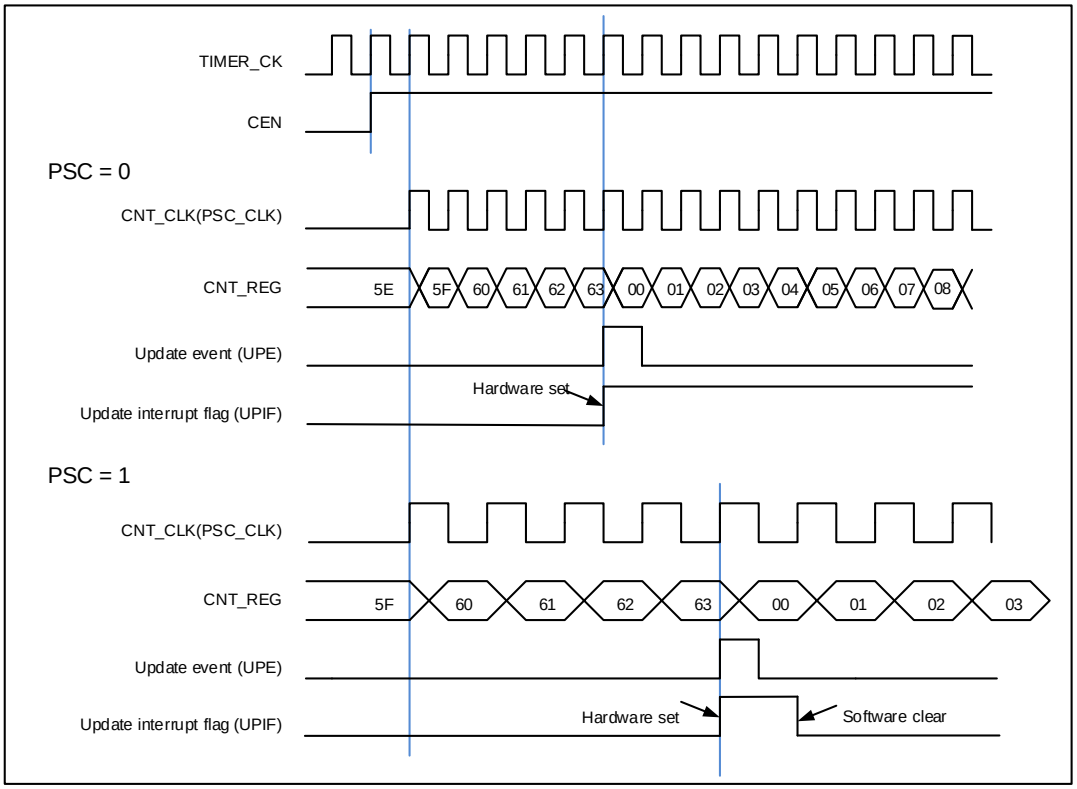


Figure 18-5. Up-counter timechart, change TIMERx_CAR on the go

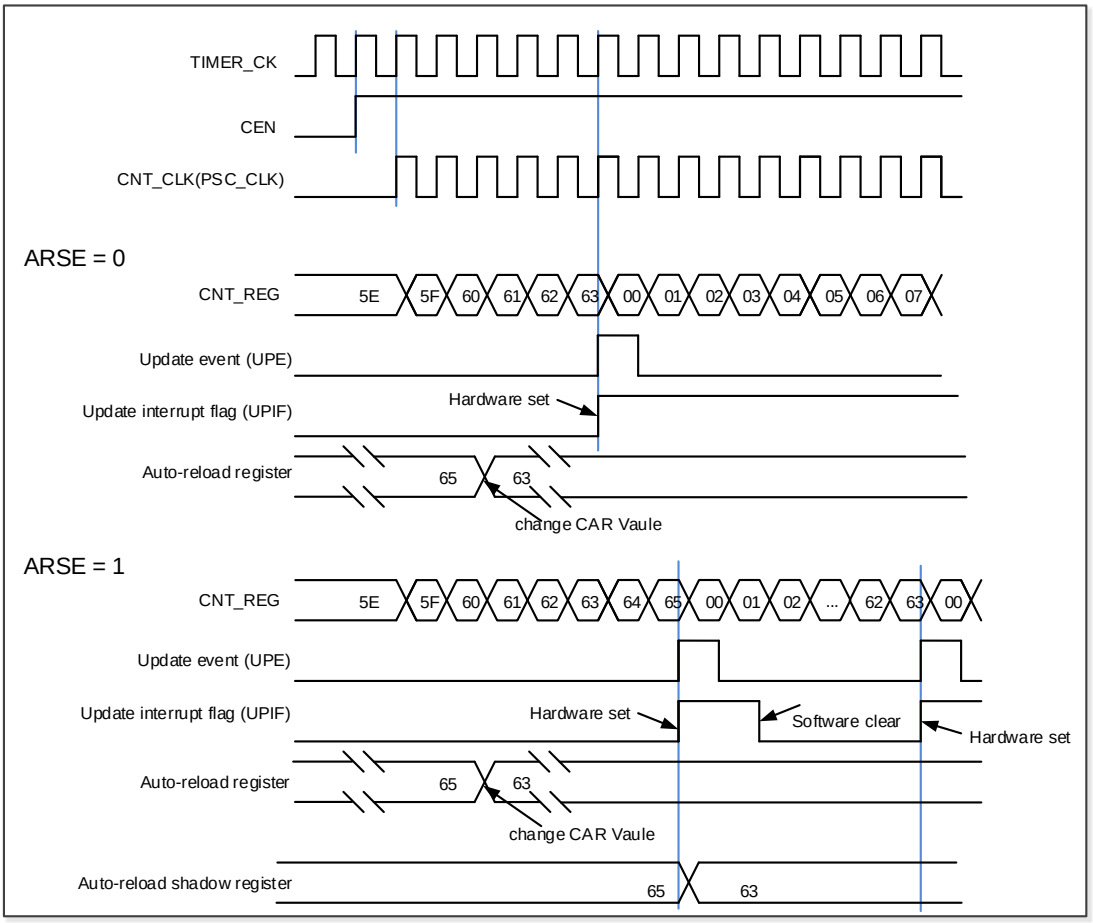

Down counting mode

In this mode, the counter counts down continuously from the counter-reload value, which is defined in the TIMERx_CAR register, to 0 in a count-down direction. Once the counter reaches to 0, the counter restarts to count again from the counter-reload value. If the repetition counter is set, the update event will be generated after (TIMERx_CREP+1) times of underflow. Otherwise the update event is generated each time when underflows. The counting direction bit DIR in the TIMERx_CTL0 register should be set to 1 for the down-counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to the counter-reload value and generates an update event.

If set the UPDIS bit in TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior in different clock

frequencies when TIMERx_CAR=0x63.

Figure 18-6. Down-counter timechart, PSC=0/1

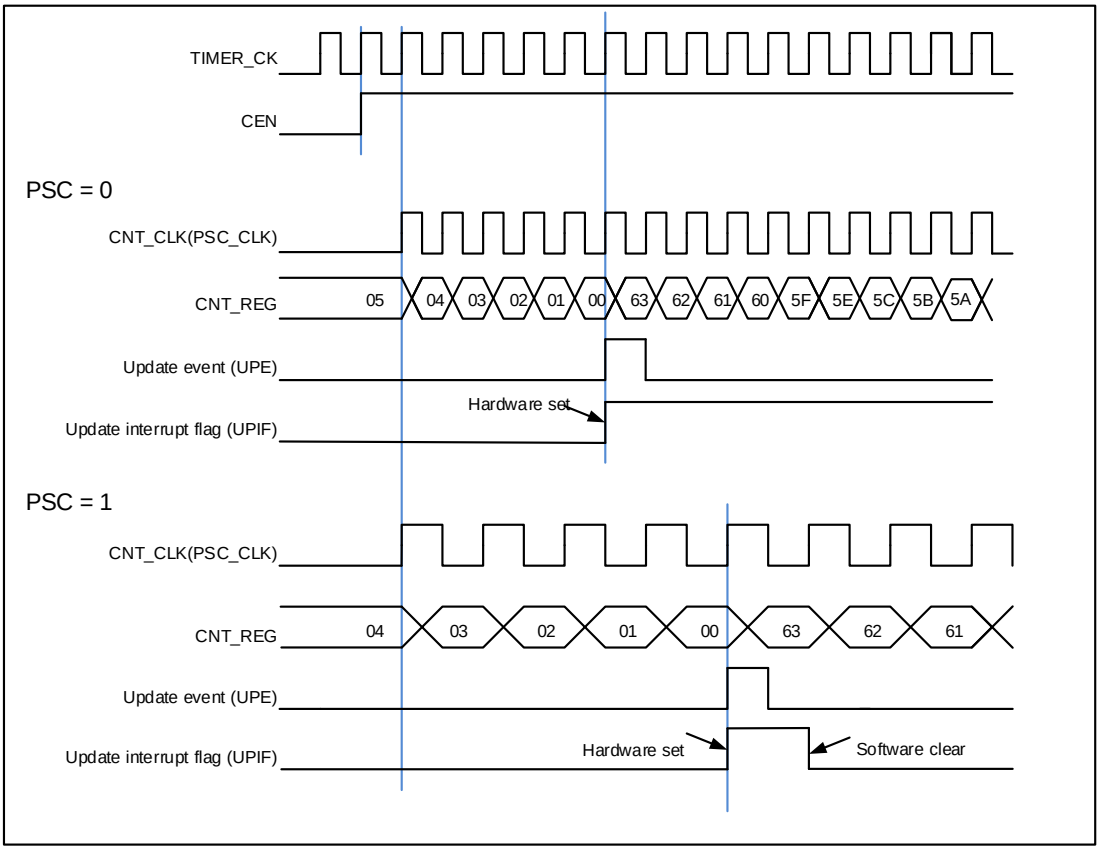

Figure 18-7. Down-counter timechart, change TIMERx_CAR on the go

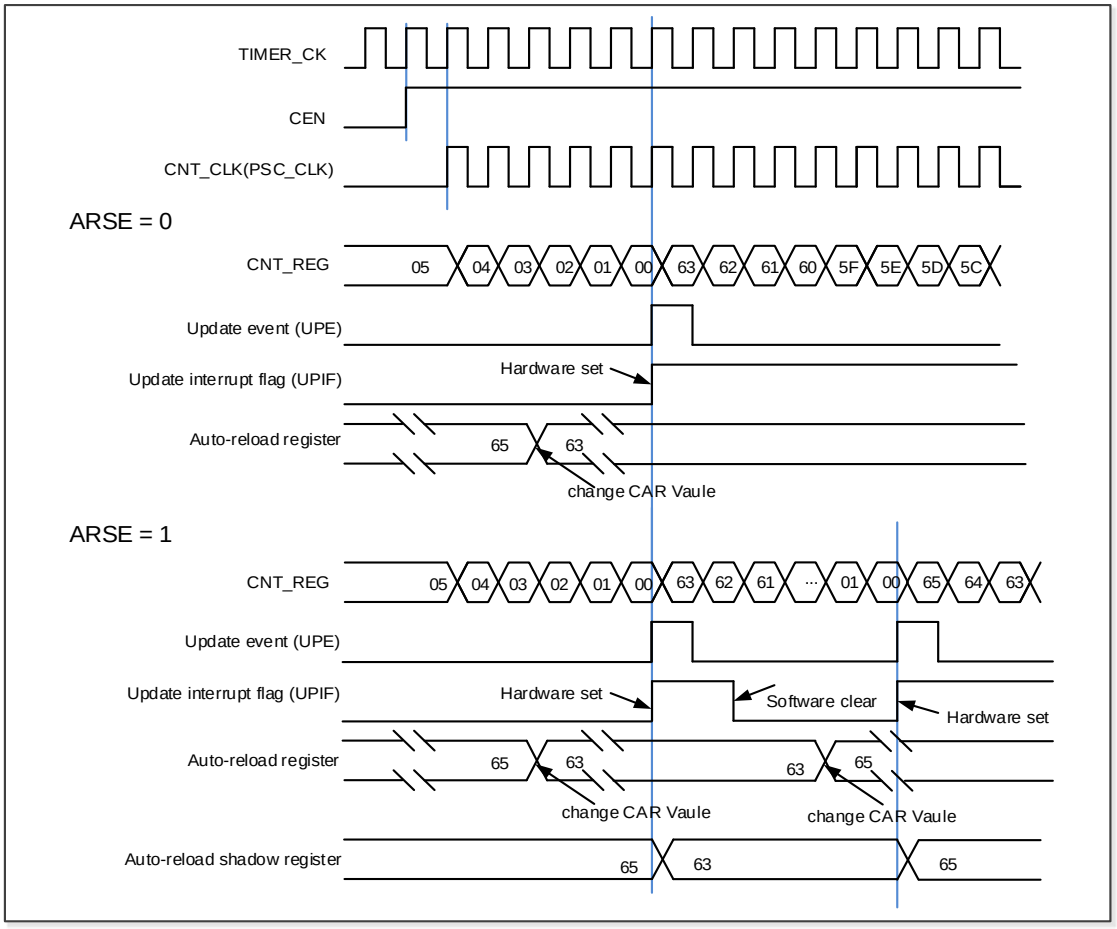


Center-aligned counting mode

In the center-aligned counting mode, the counter counts up from 0 to the counter-reload value and then counts down to 0 alternatively. The Timer module generates an overflow event when the counter counts to the counter-reload value subtract 1 in the up-counting direction and generates an underflow event when the counter counts to 1 in the down-counting direction. The counting direction bit DIR in the TIMERx_CTL0 register is read-only and indicates the counting direction when in the center-aligned mode. The counting direction is updated by hardware automatically.

Setting the UPG bit in the TIMERx_SWEVG register will initialize the counter value to 0 and generates an update event irrespective of whether the counter is counting up or down in the center-align counting mode.

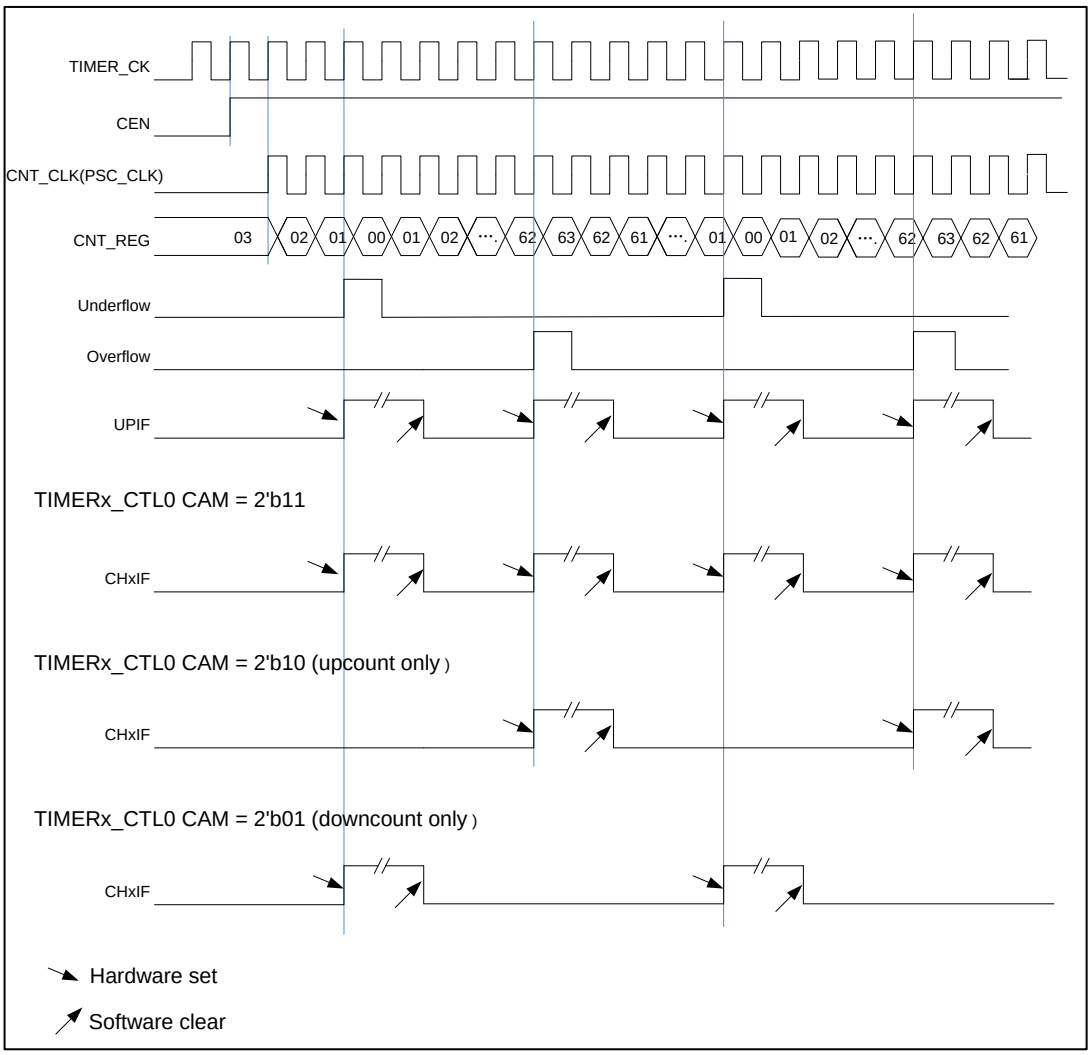
The UPIF bit in the TIMERx_INTF register can be set to 1 either when an underflow event or an overflow event occurs. While the CHxIF bit is associated with the value of CAM in TIMERx_CTL0. The details refer to ***Figure 18-8. Center-aligned counter timechart***.

If set the UPDIS bit in the TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto-reload register, prescaler register) are updated.

Figure 18-8. Center-aligned counter timechart show some examples of the counter behavior when TIMERx_CAR=0x63. TIMERx_PSC=0x0

Figure 18-8. Center-aligned counter timechart



Counter repetition

Counter Repetition is used to generator update event or updates the timer registers only after a given number (N+1) of cycles of the counter, where N is CREP in TIMERx_CREP register. The repetition counter is decremented at each counter overflow in up-counting mode, at each counter underflow in down-counting mode or at each counter overflow and at each counter underflow in center-aligned mode.

Setting the UPG bit in the TIMERx_SWEVG register will reload the content of CREP in TIMERx_CREP register and generator an update event.

For odd values of CREP in center-aligned mode, the update event occurs either on the overflow or on the underflow depending on when the CREP register was written and when the counter was started. The update event generated at overflow when the CREP was written before starting the counter, and generated at underflow when the CREP was written after starting the counter.

Figure 18-9. Repetition timecart for center-aligned counter

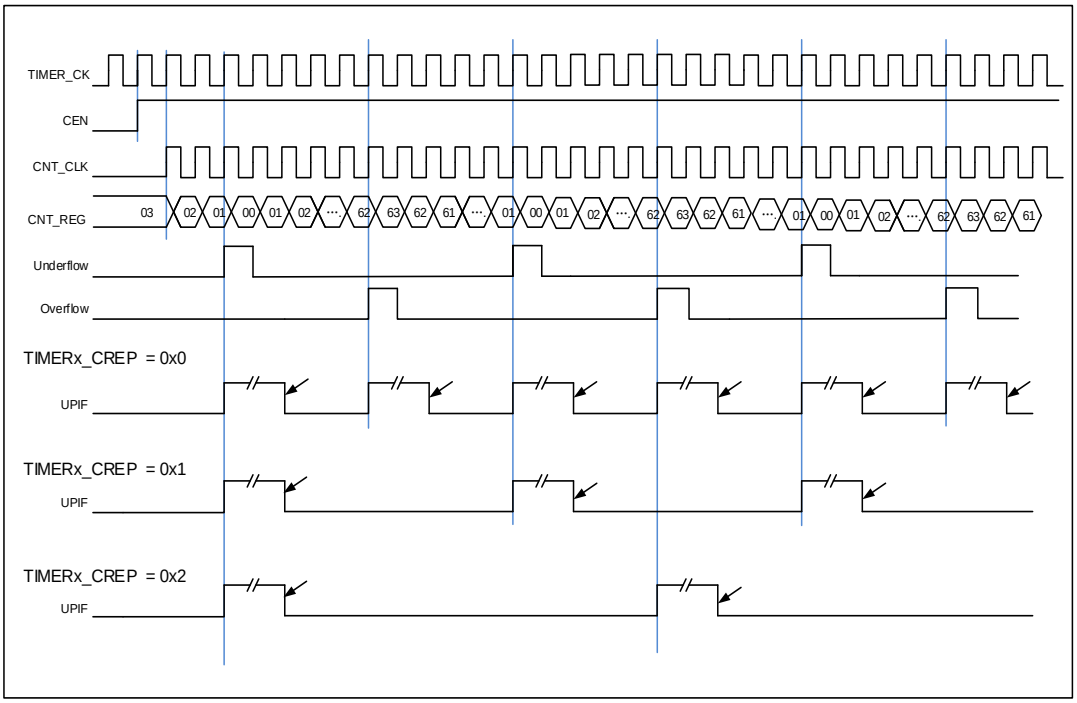


Figure 18-10. Repetition timechart for up-counter

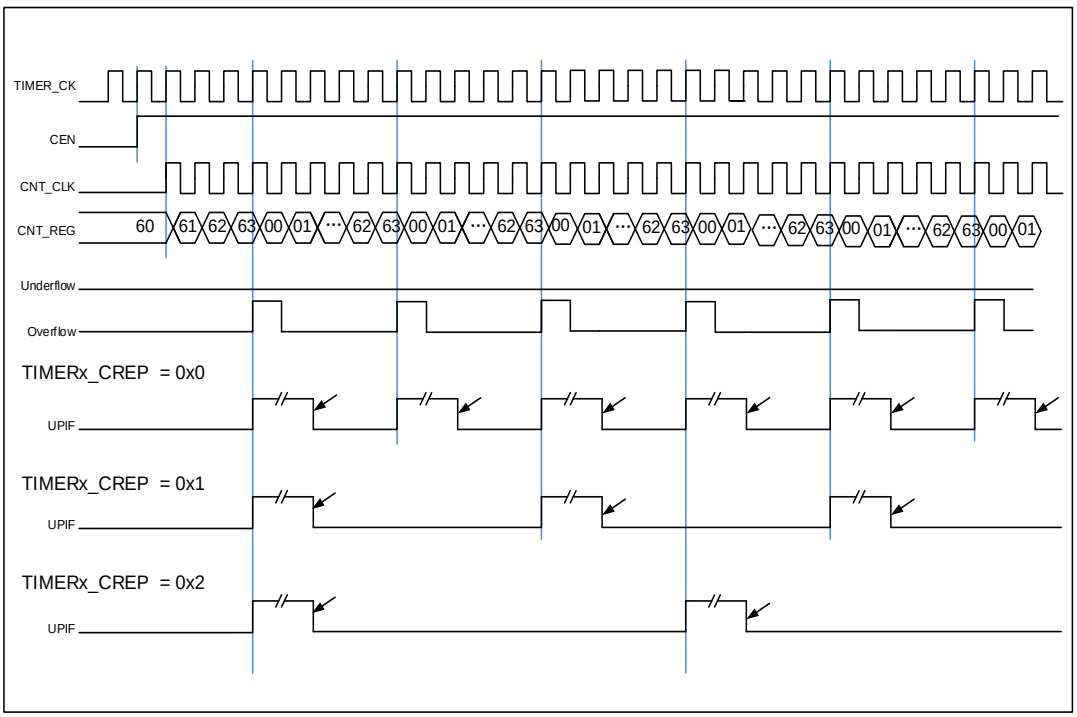

Figure 18-11. Repetition timechart for down-counter

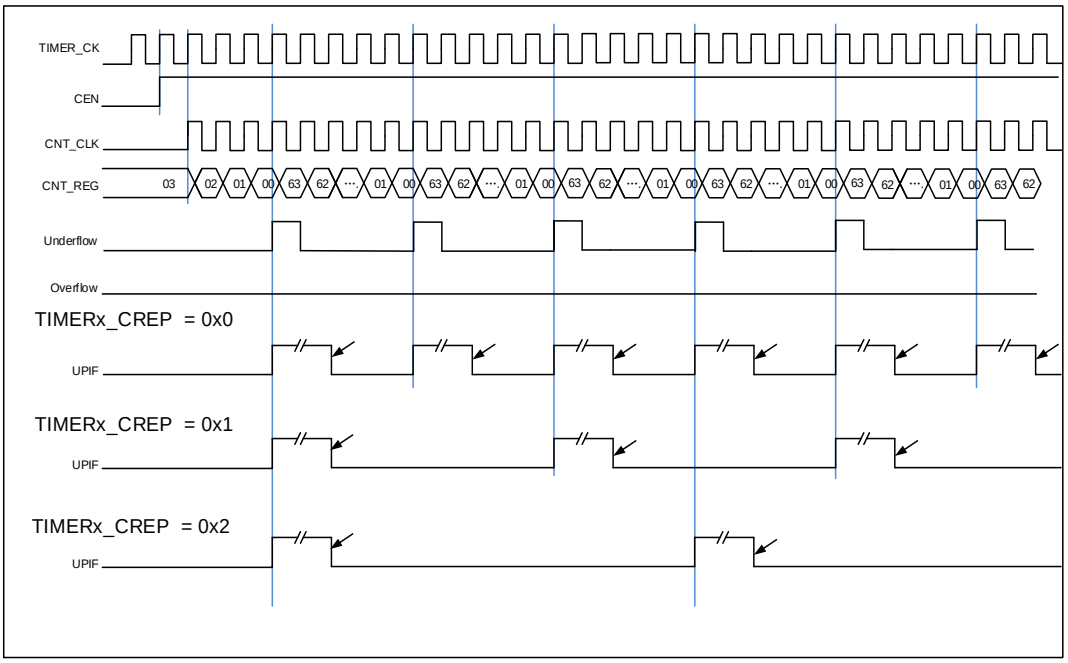


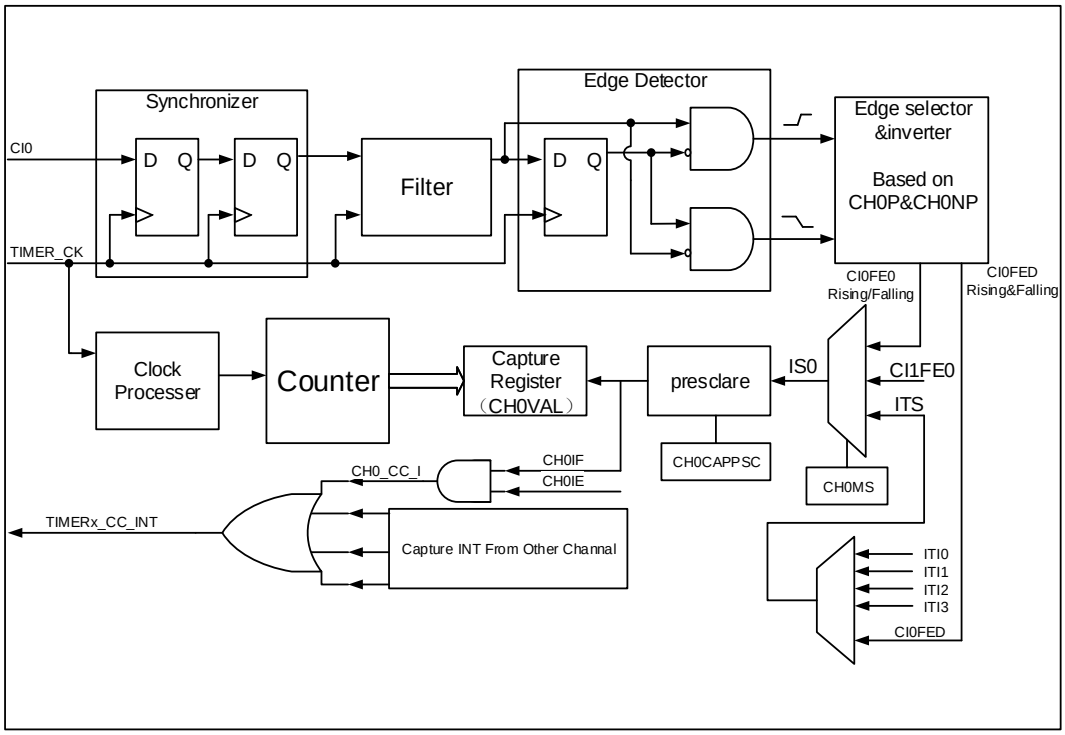
Capture/compare channels

The advanced timer has four independent channels which can be used as capture inputs or compare match outputs. Each channel is built around a channel capture compare register including an input stage, channel controller and an output stage.

- **Input capture mode**

Capture mode allows the channel to perform measurements such as pulse timing, frequency, period, duty cycle and so on. The input stage consists of a digital filter, a channel polarity selection, edge detection and a channel prescaler. When a selected edge occurs on the channel input, the current value of the counter is captured into the TIMERx_CHxCV register, at the same time the CHxIF bit is set and the channel interrupt is generated if enabled by CHxIE = 1.

Figure 18-12. Input capture logic



One of channels' input signals (CIx) can be chosen from the TIMERx_CHx signal or the Excusive-OR function of the TIMERx_CH0, TIMERx_CH1 and TIMERx_CH2 signals. First, the channel input signal (CIx) is synchronized to TIMER_CK domain, and then sampled by a digital filter to generate a filtered input signal. Then through the edge detector, the rising and falling edge are detected. You can select one of them by CHxP. One more selector is for the other channel and trig, controlled by CHxMS. Configuring the IC_prescaler enables an effective capture event after a number of input events. On the capture event, CHxVAL will restore the value of Counter.

So the process can be divided to several steps as below:

Step1: Filter configuration. (CHxCAPFLT in TIMERx_CHCTL0) Based on the input signal and requested signal quality, configure compatible CHxCAPFLT.

Step2: Edge selection. (CHxP/CHxNP in TIMERx_CHCTL2)
Rising or falling edge, choose one by CHxP/CHxNP.

Step3: Capture source selection. (CHxMS in TIMERx_CHCTL0)
As soon as you select one input capture source by CHxMS, you have set the channel to input mode (CHxMS != 0x0) and TIMERx_CHxCV cannot be written any more.

Step4: Interrupt enable. (CHxIE and CHxDEN in TIMERx_DMAINTEN)
Enable the related interrupt enable; you can got the interrupt and DMA request.

Step5: Capture enable. (CHxEN in TIMERx_CHCTL2)

Result: when you wanted input signal is got, TIMERx_CHxCV will be set by counter's value. And CHxIF is asserted. If the CHxIF has been high, the CHxOF will be asserted also.

The interrupt and DMA request will be asserted based on the configuration of CHxIE and CHxDEN in TIMERx_DMAINTEN

Direct generation: if you want to generate a DMA request or Interrupt, you can set CHxG by software directly.

The input capture mode can be also used for pulse width measurement from signals on the TIMERx_CHx pins. For example, PWM signal connect to CI0 input. Select channel 0 capture signals to CI0 by setting CH0MS to 2'b01 in the channel control register (TIMERx_CHCTL0) and set capture on rising edge. Select channel 1 capture signal to CI0 by setting CH1MS to 2'b10 in the channel control register (TIMERx_CHCTL0) and set capture on falling edge. The counter set to restart mode and restart on channel 0 rising edge. Then the TIMERx_CH0CV can measure the PWM period and the TIMERx_CH1CV can measure the PWM duty.

■ Output compare mode

In output compare mode, the TIMERx can generate timed pulses with programmable position, polarity, duration and frequency. When the counter matches the value in the CHxVAL register of an output compare channel, the channel (n) output can be set, cleared, or toggled based on CHxCOMCTL. When the counter reaches the value in the CHxVAL register, the CHxIF bit is set and the channel (n) interrupt is generated if CHxIE = 1. And the DMA request will be asserted, if CHxDEN = 1.

So the process can be divided to several steps as below:

Step1: Clock Configuration. Such as clock source, clock prescaler and so on.

Step2: Compare mode configuration.

* Set the shadow enable mode by CHxCOMSEN
* Set the output mode (Set/Clear/Toggle) by CHxCOMCTL.
* Select the active high polarity by CHxP/CHxNP
* Enable the output by CHxEN

Step3: Interrupt/DMA-request enables configuration by CHxIE/CHxDEN.

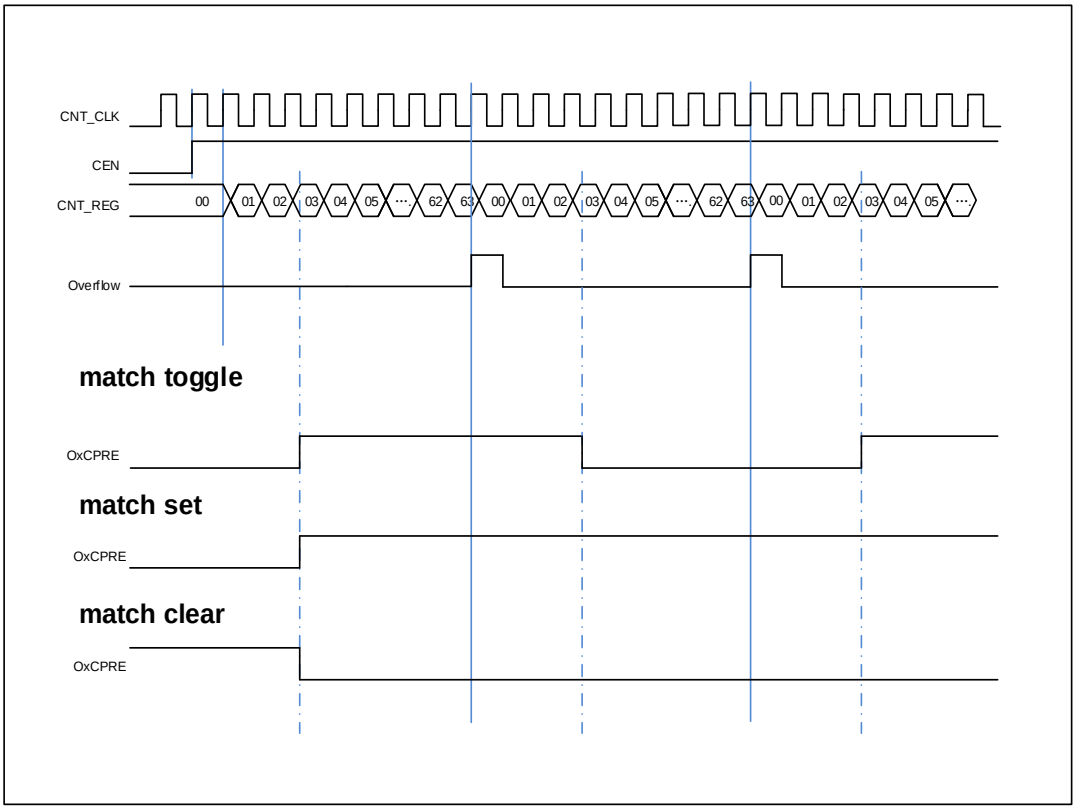
Step4: Compare output timing configuration by TIMERx_CAR and TIMERx_CHxCV

About the CHxVAL; you can change it on the go to meet the waveform you expected.

Step5: Start the counter by CEN.

The timechart below shows the three compare modes toggle/set/clear. CAR=0x63, CHxVAL=0x3

Figure 18-13. Output-compare under three modes



PWM mode

In the output PWM mode (by setting the CHxCOMCTL bits to 3'b110 (PWM mode0) or to 3'b 111(PWM mode1), the channel can generate PWM waveform according to the TIMERx_CAR registers and TIMERx_CHxCV registers.

Based on the counter mode, we can also divide PWM into EAPWM (Edge aligned PWM) and CAPWM (Centre aligned PWM).

The EAPWM period is determined by TIMERx_CAR and duty cycle is determined by TIMERx_CHxCV. ***Figure 18-14. EAPWM timechart*** shows the EAPWM output and interrupts waveform.

The CAPWM period is determined by 2*TIMERx_CAR, and duty cycle is by 2*TIMERx_CHxCV. ***Figure 18-15. CAPWM timechart*** shows the CAPWM output and interrupts waveform.

If TIMERx_CHxCV is greater than TIMERx_CAR, the output will be always active under PWM mode0 (CHxCOMCTL = 3'b110).
And if TIMERx_CHxCV is equal to zero, the output will be always inactive under PWM mode0 (CHxCOMCTL = 3'b110).

Figure 18-14. EAPWM timechart

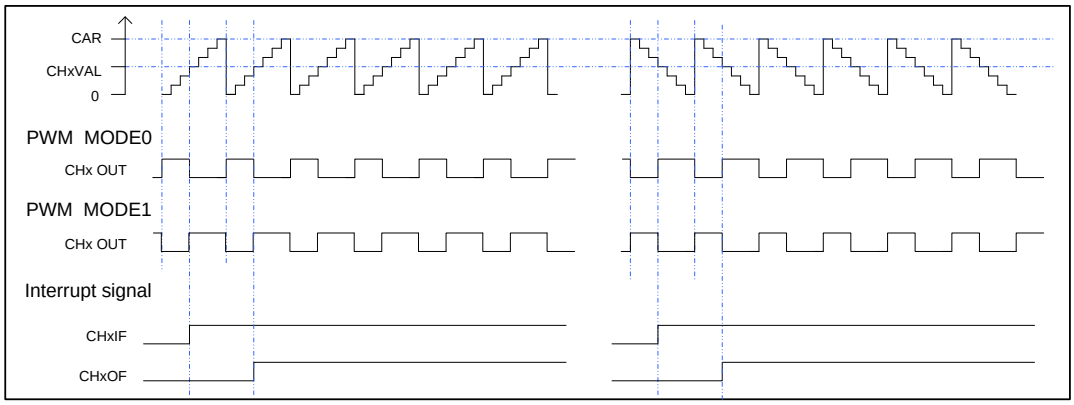


Figure 18-15. CAPWM timechart

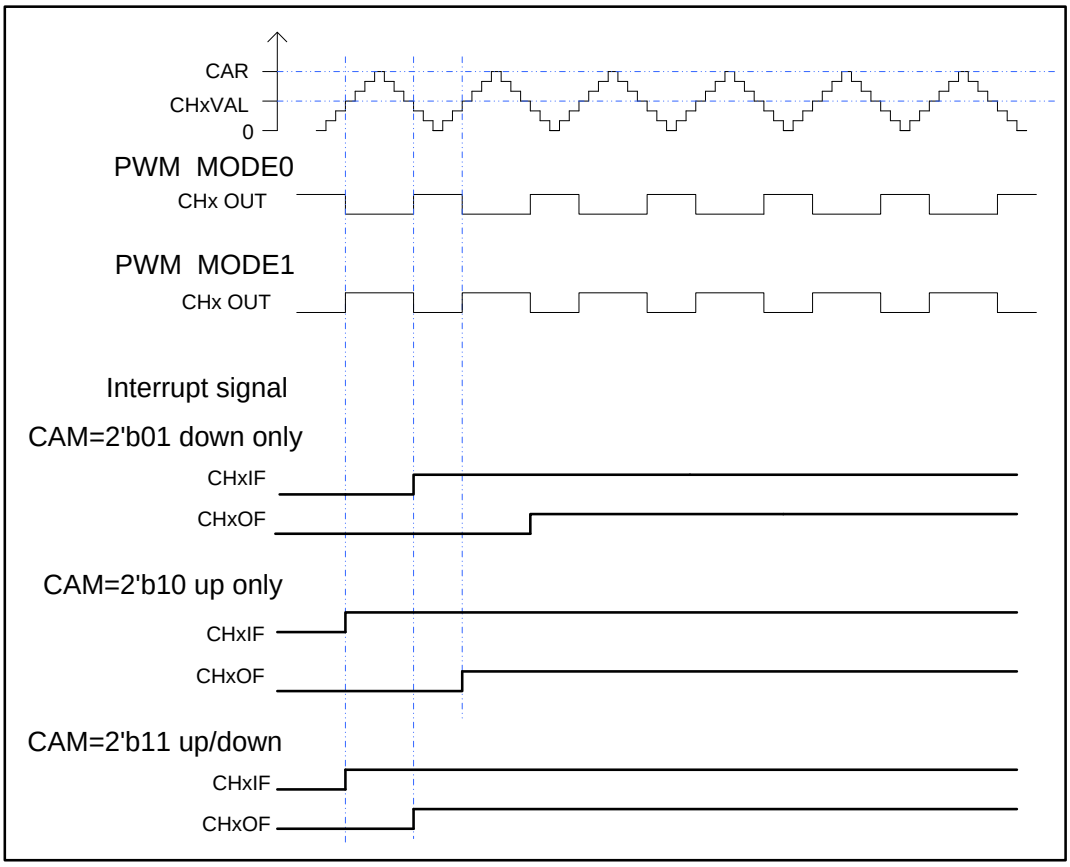

Channel output reference signal

When the TIMERx is used in the compare match output mode, the OxCPRE signal (Channel x Output prepare signal) is defined by setting the CHxCOMCTL filed. The OxCPRE signal has several types of output function. These include, keeping the original level by setting the CHxCOMCTL field to 0x00, set to 1 by setting the CHxCOMCTL field to 0x01, set to 0 by setting the CHxCOMCTL field to 0x02 or signal toggle by setting the CHxCOMCTL field to 0x03 when the counter value matches the content of the TIMERx_CHxCV register.

The PWM mode 0 and PWM mode 1 outputs are also another kind of OxCPRE output which

is setup by setting the CHxCOMCTL field to 0x06/0x07. In these modes, the OxCPRE signal level is changed according to the counting direction and the relationship between the counter value and the TIMERx_CHxCV content. With regard to a more detail description refer to the relative bit definition.

Another special function of the OxCPRE signal is a forced output which can be achieved by setting the CHxCOMCTL field to 0x04/0x05. Here the output can be forced to an inactive/active level irrespective of the comparison condition between the counter and the TIMERx_CHxCV values.

The OxCPRE signal can be forced to 0 when the ETIFE signal is derived from the external ETI pin and when it is set to a high level by setting the CHxCOMCEN bit to 1 in the TIMERx_CHCTL0 register. The OxCPRE signal will not return to its active level until the next update event occurs.

Outputs complementary

Function of complementary is for a pair of CHx_O and CHx_ON. Those two output signals cannot be active at the same time. The TIMERx has 4 channels, but only the first three channels have this function. The complementary signals CHx_O and CHx_ON are controlled by a group of parameters: the CHxEN and CHxNEN bits in the TIMERx_CHCTL2 register and the POEN, ROS, IOS, ISOx and ISOxN bits in the TIMERx_CCHP and TIMERx_CTL1 registers. The outputs polarity is determined by CHxP and CHxNP bits in the TIMERx_CHCTL2 register.

Table 18-2. Complementary outputs controlled by parameters

<table>
<tr><th colspan="5">Complementary Parameters</th><th colspan="2">Output Status</th></tr>

Complementary Parameters					Output Status	
POEN	ROS	IOS	CHxEN	CHxNEN	CHx_O	CHx_ON
1	0	0/1	0	0	CHx_O/CHx_ON = LOW CHx_O/CHx_ON output disable.	
				1	CHx_O = LOW CHx_O output disable.	CHx_ON=OxCPRE⊕CHxNP CHx_ON output enable
			1	0	CHx_O=OxCPRE ⊕ CHxP CHx_O output enable	CHx_ON = LOW CHx_ON output disable.
				1	CHx_O=OxCPRE ⊕ CHxP CHx_O output enable	CHx_ON=OxCPRE⊕CHxNP CHx_ON output enable
	1		0	0	CHx_O = CHxP CHx_O output disable.	CHx_ON = CHxNP CHx_ON output disable.
				1	CHx_O = CHxP CHx_O output enable	CHx_ON=OxCPRE⊕CHxNP CHx_ON output enable
			1	0	CHx_O=OxCPRE ⊕ CHxP CHx_O output enable	CHx_ON = CHxNP CHx_ON output enable.
				1	CHx_O=OxCPRE ⊕ CHxP CHx_O output enable	CHx_ON=OxCPRE⊕CHxNP CHx_ON output enable.

Dead time insertion

The dead time insertion is enabled when both CHxEN and CHxNEN are 1'b1, and set POEN is also necessary. The field named DTCFG defines the dead time delay that can be used for all channels expect for channel 3. The detail about the delay time, refer to the register TIMERx_CCHP.

The dead time delay insertion ensures that no two complementary signals drive the active state at the same time.

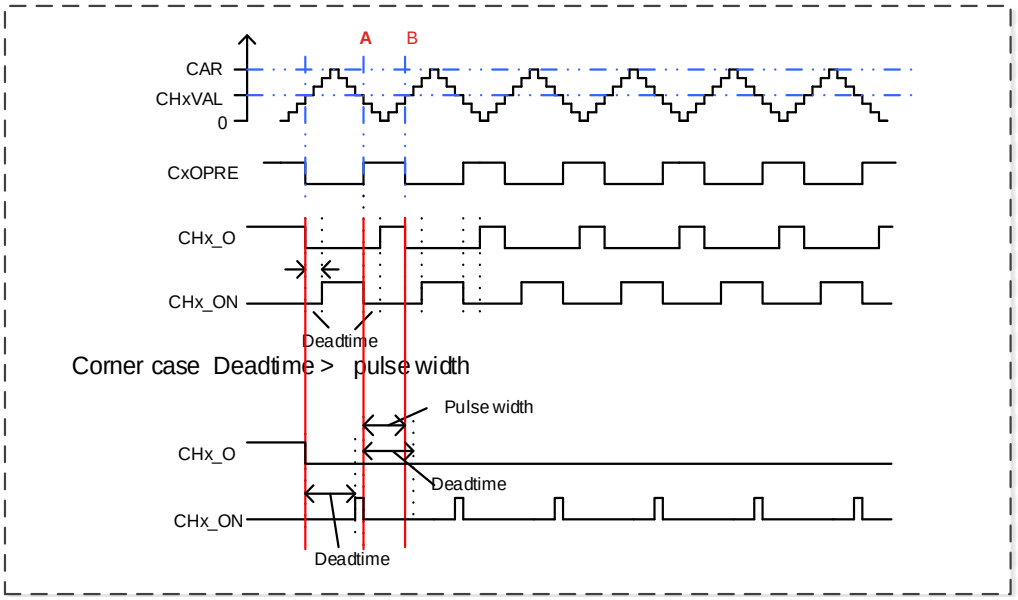
When the channel (x) match (TIMERx counter = CHxVAL) occurs, OxCPRE will be toggled because under PWM0 mode. At point A in the ***Figure 18-16. Complementary output with dead-time insertion*** CHx_O signal remains at the low value until the end of the deadtime delay, while CHx_ON will be cleared at once. Similarly, At point B when counter match (counter = CHxVAL) occurs again, OxCPRE is cleared, CHx_O signal will be cleared at once,

while CHx_ON signal remains at the low value until the end of the dead time delay.

Sometimes, we can see corner cases about the dead time insertion. For example:

The dead time delay is greater than or equal to the CHx_O duty cycle, then the CHx_O signal is always the inactive value. (as show in the ***Figure 18-16. Complementary output with dead-time insertion***)

Figure 18-16. Complementary output with dead-time insertion



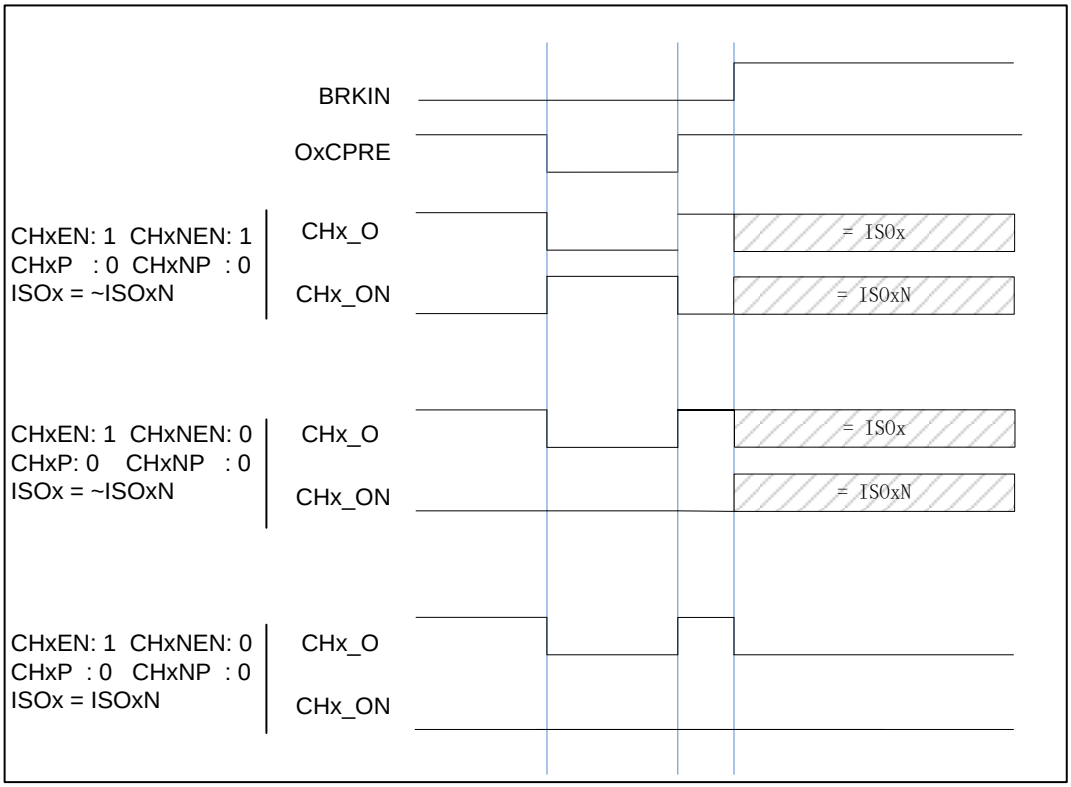
Break function

In this function, the output CHx_O and CHx_ON are controlled by the POEN, IOS and ROS bits in the TIMERx_CCHP register, ISOx and ISOxN bits in the TIMERx_CTL1 register and cannot be set both to active level when break occurs. The break sources are input break pin and HXTAL stuck event by Clock Monitor (CKM) in RCU. The break function enabled by setting the BRKEN bit in the TIMERx_CCHP register. The break input polarity is setting by the BRKP bit in TIMERx_CCHP.

When a break occurs, the POEN bit is cleared asynchronously, the output CHx_O and CHx_ON are driven with the level programmed in the ISOx bit and ISOxN in the TIMERx_CTL1 register as soon as POEN is 0. If IOS is 0 then the timer releases the output enable, otherwise the output enable remains high. The complementary outputs are first put in reset state, and then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the ISOx and ISOxN bits after a dead-time.

When a break occurs, the BRKIF bit in the TIMERx_INTF register is set. If BRKIE is 1, an interrupt generated.

Figure 18-17. Output behavior in response to a break (The break high active)



Quadrature decoder

The quadrature decoder function uses two quadrature inputs CI0 and CI1 derived from the TIMERx_CH0 and TIMERx_CH1 pins respectively to interact to generate the counter value. The DIR bit is modified by hardware automatically during each input source transition. The input source can be either CI0 only, CI1 only or both CI0 and CI1, the selection mode by setting the SMC [2:0] to 0x01, 0x02 or 0x03. The mechanism for changing the counter direction is shown in the following table. The quadrature decoder can be regarded as an external clock with a directional selection. This means that the counter counts continuously in the interval between 0 and the counter-reload value. Therefore, users must configure the TIMERx_CAR register before the counter starts to count.

Table 18-3. Counting direction versus encoder signals

Counting mode	Level	CI0FE0		CI1FE1	
		Rising	Falling	Rising	Falling
CI0 only counting	CI1FE1=High	Down	Up	-	-
	CI1FE1=Low	Up	Down	-	-
CI1 only counting	CI0FE0=High	-	-	Up	Down
	CI0FE0=Low	-	-	Down	Up
CI0 and CI1 counting	CI1FE1=High	Down	Up	X	X
	CI1FE1=Low	Up	Down	X	X
	CI0FE0=High	X	X	Up	Down
	CI0FE0=Low	X	X	Down	Up

Note:"-" means "no counting"; "X" means impossible.

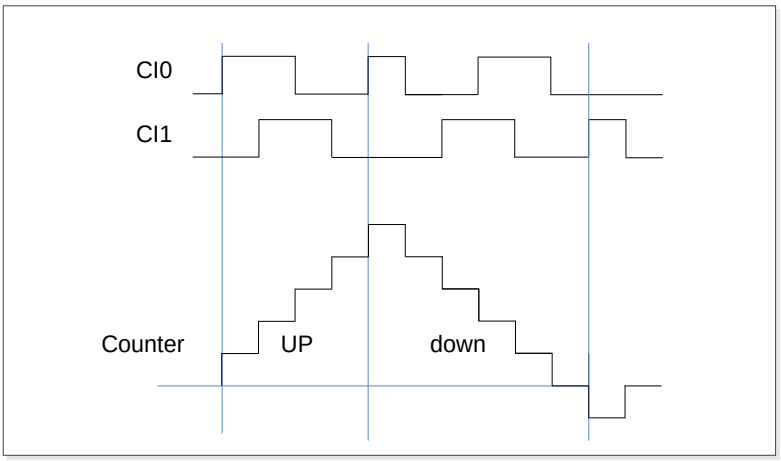

Figure 18-19. Example of encoder interface mode with CI0FE0 polarity inverted

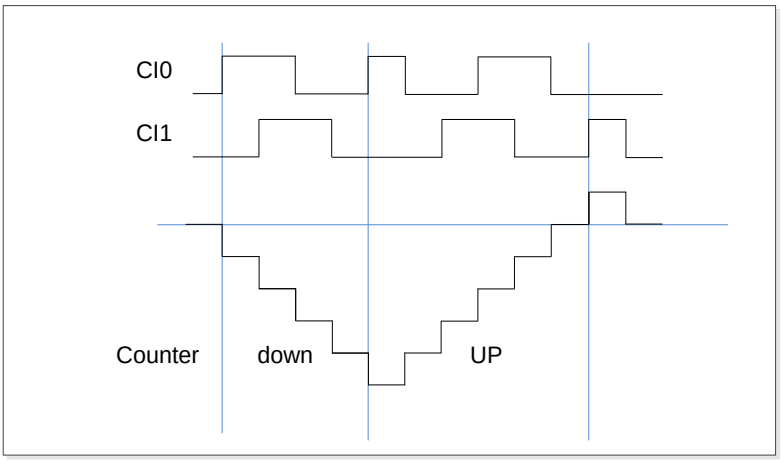

Hall sensor function

Hall sensor is generally used to control BLDC Motor; advanced timer can support this function.

Figure 18-20. Hall sensor is used to BLDC motor show how to connect. And we can see we need two timers. First TIMER_in（Advanced/GeneralL0 TIMER） should accept three Rotor Position signals from Motor.

Each of the 3 sensors provides a pulse that applied to an input capture pin, can then be analyzed and both speed and position can be deduced.

By the internal connection such as TRGO-ITIx, TIMER_in and TIMER_out can be connected. TIMER_out will generate PWM signal to control BLDC motor's speed based on the ITRx. Then, the connection between the TIMER_in and TIMER_out forms a feedback circuit that can be configured according to requirements.

About the TIMER_in, it needs to have input XOR function, so you can choose from

Advanced/GeneralL0 TIMER.

And TIMER_out needs to have functions of complementary and Dead-time, so only advanced timer can be chosen. In addition, based on the timers' internal connection relationship, pair's timers can be selected. For example:

TIMER_in (TIMER0) -> TIMER_out (TIMER7 ITI0)

TIMER_in (TIMER1) -> TIMER_out (TIMER0 ITI1)

And so on.

After getting appropriate timers combination, and wire connection, we need to configure timers. Some key settings include:

- Enable XOR by setting TI0S, then, each change of input signal will make the CI0 toggle. CH0VAL will record the value of counter at that moment.
- Enable ITIx connected to commutation function directly by setting CCUC and CCSE.
- Configuration PWM parameter based on your request.

Figure 18-20. Hall sensor is used to BLDC motor

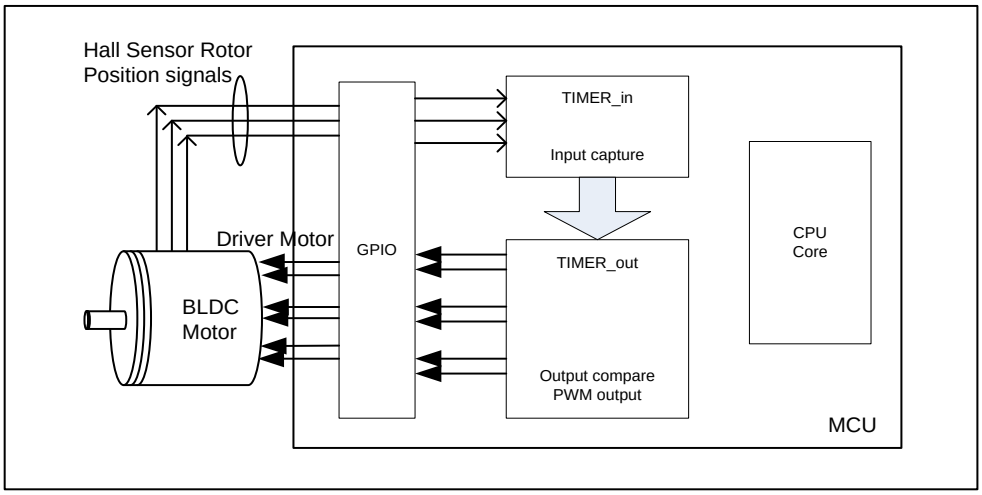

Figure 18-21. Hall sensor timing between two timers

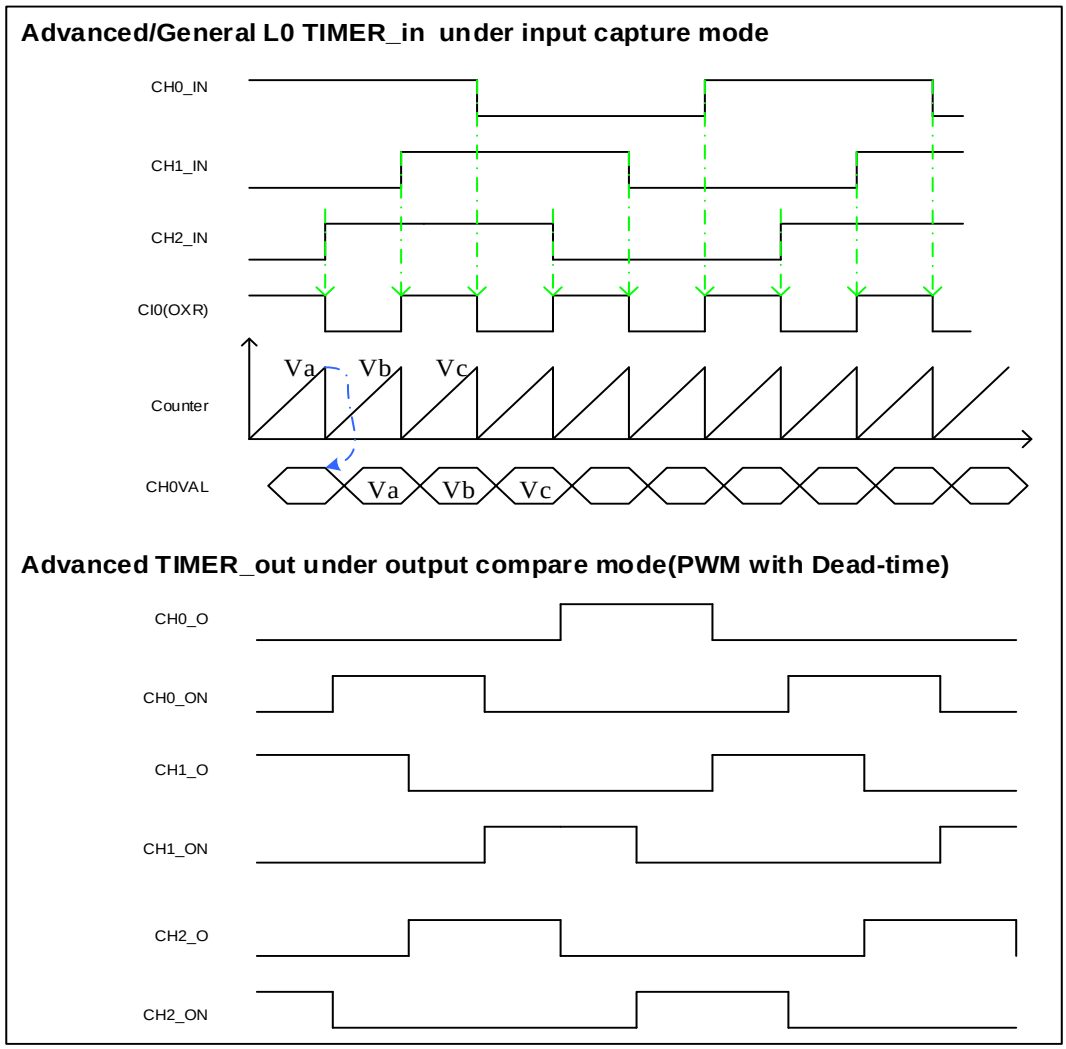


Slave controller

The TIMERx can be synchronized with a trigger in several modes including the restart mode, the pause mode and the event mode which is selected by the SMC [2:0] in the TIMERx_SMCFG register. The trigger input of these modes can be selected by the TRGS [2:0] in the TIMERx_SMCFG register.

Table 18-4. Slave mode example table

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
LIST	SMC[2:0] 3'b100 (restart mode) 3'b101 (pause mode) 3'b110 (event mode)	TRGS[2:0] 000: ITI0 001: ITI1 010: ITI2 011: ITI3 100: CI0F_ED 101: CI0FE0 110: CI1FE1 111: ETIFP	If you choose the CI0FE0 or CI1FE1, configure the CHxP and CHxNP for the polarity selection and inversion. If you choose the ETIF, configure the ETP for polarity selection and inversion.	For the ITIx no filter and prescaler can be used. For the CIx, configure Filter by CHxCAPFLT, no prescaler can be used. For the ETIF, configure Filter by ETFC and Prescaler by ETPSC.
Exam1	Restart mode The counter can be clear and restart when a rising trigger input.	TRGS[2:0]=3'b000 ITI0 is the selection.	- For ITI0, no polarity selector can be used.	- For the ITI0, no filter and prescaler can be used.
	Figure 18-22. Restart mode 			
Exam2	Pause mode The counter can be paused when the trigger input is low.	TRGS[2:0]=3'b101 CI0FE0 is the selection.	TI0S=0.（Non-xor）[CH0NP==0, CH0P==0] no inverted. Capture will be sensitive to the rising edge only.	Filter is bypass in this example.

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
	Figure 18-23. Pause mode 			
Exam3	Event mode The counter will start to count when a rising trigger input.	TRGS[2:0]=3'b111 ETIF is the selection.	ETP = 0 no polarity change.	ETPSC = 1, divided by 2. ETFC = 0 , no filter
	Figure 18-24. Event mode 			

Single pulse mode

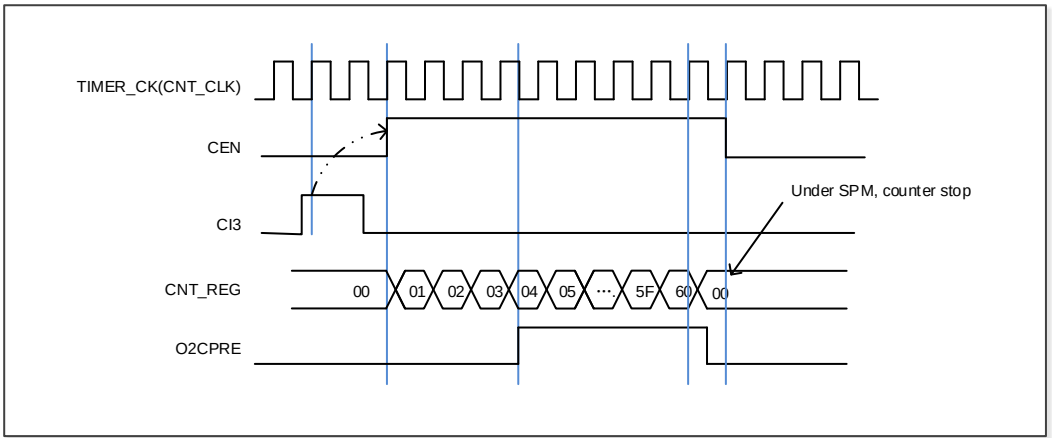
Single pulse mode is opposite to the repetitive mode, which can be enabled by setting SPM in TIMERx_CTL0. When you set SPM, the counter will be clear and stop when the next update event automatically. In order to get pulse waveform, you can set the TIMERx to PWM mode or compare by CHxCOMCTL.

Once the timer is set to operate in the single pulse mode, it is not necessary to set the timer enable bit CEN in the TIMERx_CTL0 register to 1 to enable the counter. The trigger to generate a pulse can be sourced from the trigger signals edge or by setting the CEN bit to 1 using software. Setting the CEN bit to 1 or a trigger from the trigger signals edge can generate a pulse and then keep the CEN bit at a high state until the update event occurs or the CEN

bit is written to 0 by software. If the CEN bit is cleared to 0 using software, the counter will be stopped and its value held. If the CEN bit is automatically cleared to 0 by a hardware update event, the counter will be reinitialized.

In the single pulse mode, the trigger active edge which sets the CEN bit to 1 will enable the counter. However, there exist several clock delays to perform the comparison result between the counter value and the TIMERx_CHxCV value. In order to reduce the delay to a minimum value, the user can set the CHxCOMFEN bit in each TIMERx_CHCTL0/1 register. After a trigger rising occurs in the single pulse mode, the OxCPRE signal will immediately be forced to the state which the OxCPRE signal will change to, as the compare match event occurs without taking the comparison result into account. The CHxCOMFEN bit is available only when the output channel is configured to operate in the PWM0 or PWM1 output mode and the trigger source is derived from the trigger signal.

Figure 18-25. Single pulse mode, TIMERx_CHxCV = 0x04, TIMERx_CAR=0x60

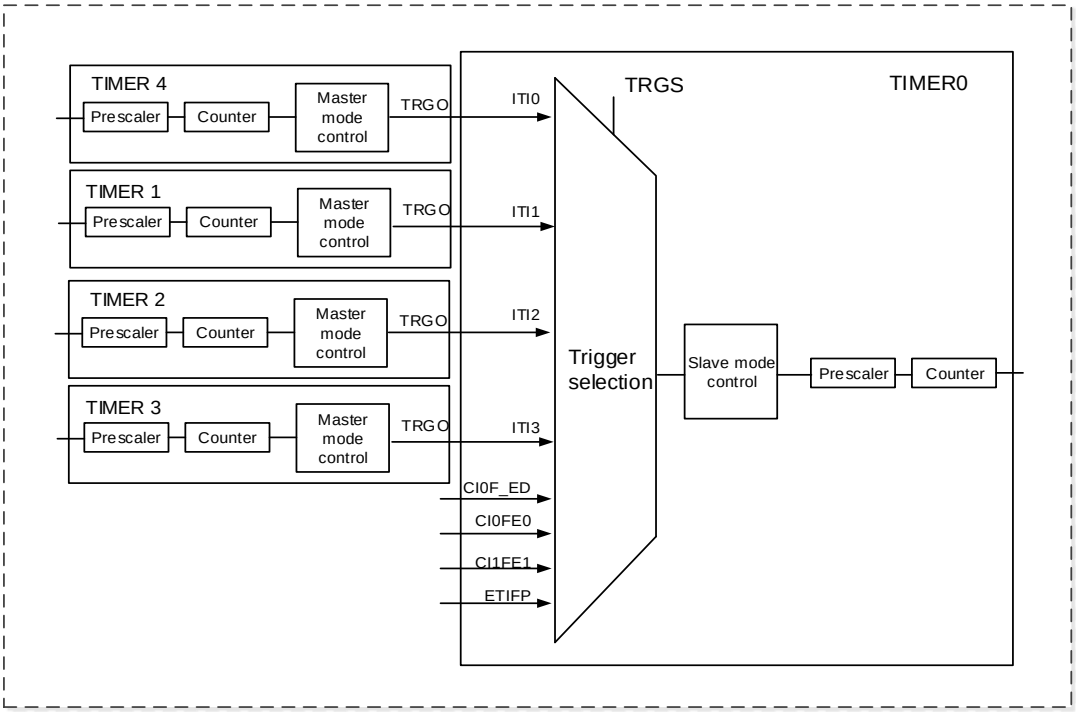


Timers interconnection

The timers can be internally connected together for timer chaining or synchronization. This can be implemented by configuring one timer to operate in the master mode while configuring another timer to be in the slave mode. The following figures present several examples of trigger selection for the master and slave modes.

Figure 18-26. Timer0 master/slave mode timer example shows the timer0 trigger selection when it is configured in slave mode.

Figure 18-26. Timer0 master/slave mode timer example



Other interconnection examples:

- Timer 2 as prescaler for timer 0

We configure Timer2 as a prescaler for Timer 0. Refer to ***Figure 18-26. Timer0 master/slave mode timer example*** for connections. Do as bellow:

1. Configure Timer2 in master mode and select its update event (UPE) as trigger output (MMC=3'b010 in the TIMER2_CTL1 register). Then timer2 drives a periodic signal on each counter overflow.
2. Configure the Timer2 period (TIMER2_CAR registers).
3. Select the Timer0 input trigger source from Timer2 (TRGS=3'b010 in the TIMERx_SMCFG register).
4. Configure Timer0 in external clock mode 0 (SMC=3'b111 in TIMERx_SMCFG register).
5. Start Timer0 by writing '1 in the CEN bit (TIMER0_CTL0 register).
6. Start Timer2 by writing '1 in the CEN bit (TIMER2_CTL0 register).

- Start timer0 with timer2's Enable/Update signal

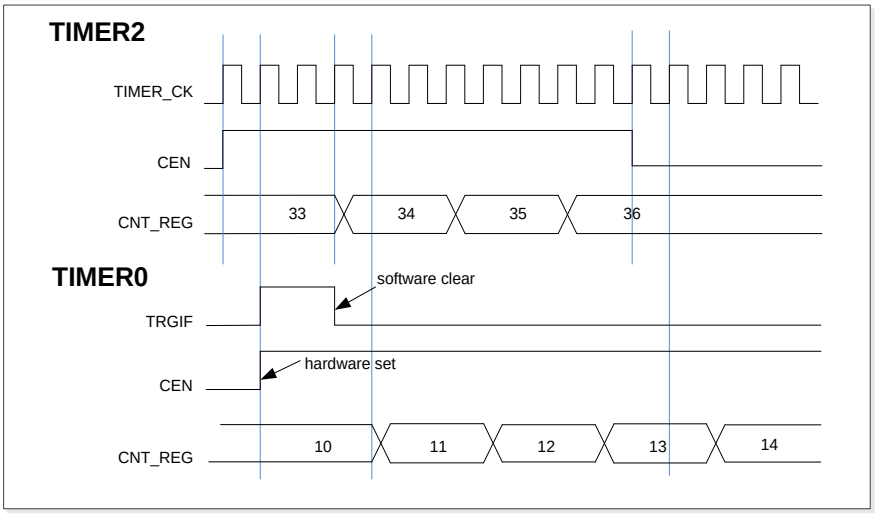
In this example, we enable Timer0 with the enable output of Timer2. Refer to ***Figure 18-27. Triggering TIMER0 with enable signal of TIMER2***. Timer0 starts counting from its current value on the divided internal clock after trigger by timer2 enable output.

When Timer0 receives the trigger signal, its CEN bit is set automatically and the counter counts until we disable timer0. In this example, both counter clock frequencies are divided by

3 by the prescaler compared to TIMER_CK ($f_{CNT\_CLK} = f_{TIMER\_CK}/3$). Timer0's SMC is set as event mode, so Timer0 can not be disabled by Timer2's disable signal. Do as follow:

1. Configure Timer2 master mode to send its enable signal as trigger output(MMC=3'b001 in the TIMER2_CTL1 register)
2. Configure Timer0 to select the input trigger from Timer2 (TRGS=3'b010 in the TIMERx_SMCFG register).
3. Configure Timer0 in event mode (SMC=3'b 110 in TIMERx_SMCFG register).
4. Start Timer2 by writing 1 in the CEN bit (TIMER2_CTL0 register).

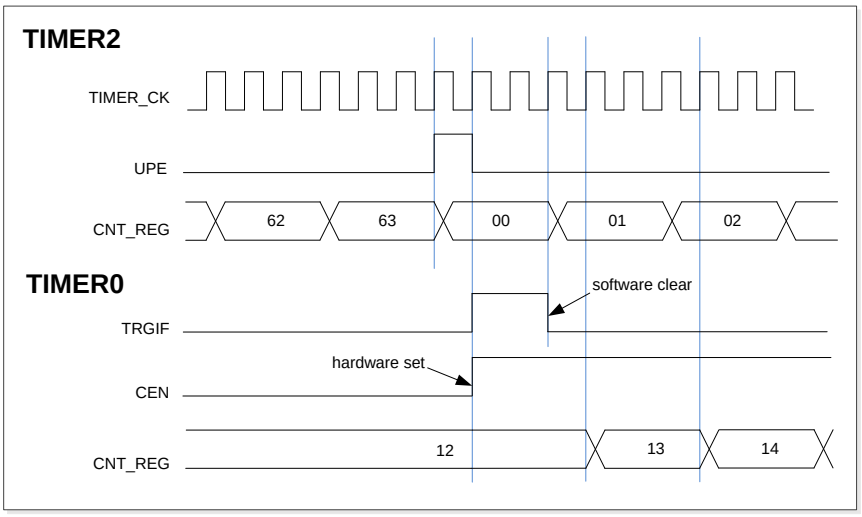
Figure 18-27. Triggering TIMER0 with enable signal of TIMER2



In this example, we also can use update Event as trigger source instead of enable signal. Refer to ***Figure 18-28. Triggering TIMER0 with update signal of TIMER2***. Do as follow:

1. Configure Timer2 in master mode and send its update event (UPE) as trigger output (MMC=3'b010 in the TIMER2_CTL1 register).
2. Configure the Timer2 period (TIMER2_CARL registers).
3. Configure Timer0 to get the input trigger from Timer2 (TRGS=3'b010 in the TIMERx_SMCFG register).
4. Configure Timer0 in event mode (SMC=3'b110 in TIMERx_SMCFG register).
5. Start Timer2 by writing '1 in the CEN bit (TIMER2_CTL0 register).

Figure 18-28. Triggering TIMER0 with update signal of TIMER2

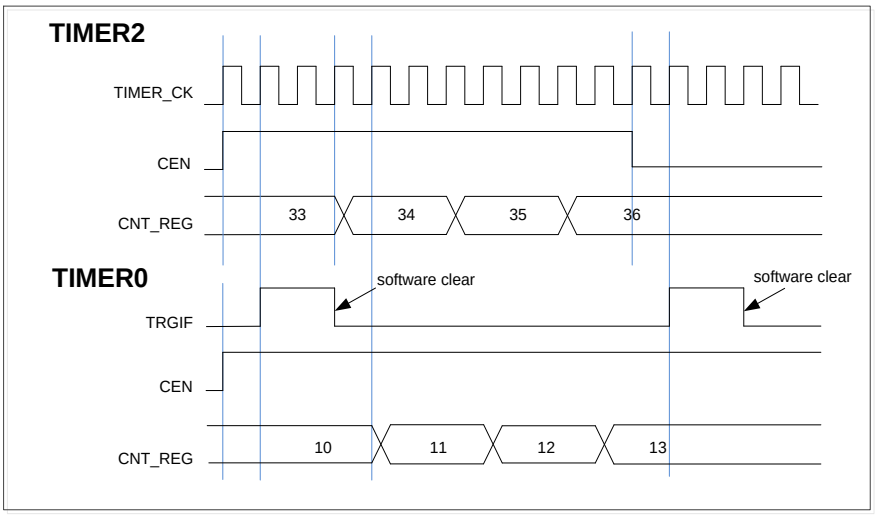


- Enable Timer0 count with Timer2's enable/O0CPRE signal

In this example, we control the enable of Timer0 with the enable output of Timer2 .Refer to ***Figure 18-29. Pause TIMER0 with enable signal of TIMER2***. Timer0 counts on the divided internal clock only when Timer 2 is enable. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_TIMER (fCNT_CLK = fPCLK /3). Timer0's SMC is set as pause mode, so Timer0 can be enabled/disabled by Timer2's enable/disable signal. Do as follow:

1. Configure Timer2 in input master mode and its output enable signal as trigger output (MMC=3'b001 in the TIMER2_CTL1 register).
2. Configure Timer0 to get the input trigger from Timer2 (TRGS=3'b010 in the TIMERx_SMCFG register).
3. Configure Timer0 in pause mode (SMC=3'b101 in TIMERx_SMCFG register).
4. Enable Timer0 by writing '1 in the CEN bit (TIMER0_CTL0 register)
5. Start Timer2 by writing '1 in the CEN bit (TIMER2_CTL0 register).
6. Stop Timer2 by writing '0 in the CEN bit (TIMER2_CTL0 register).

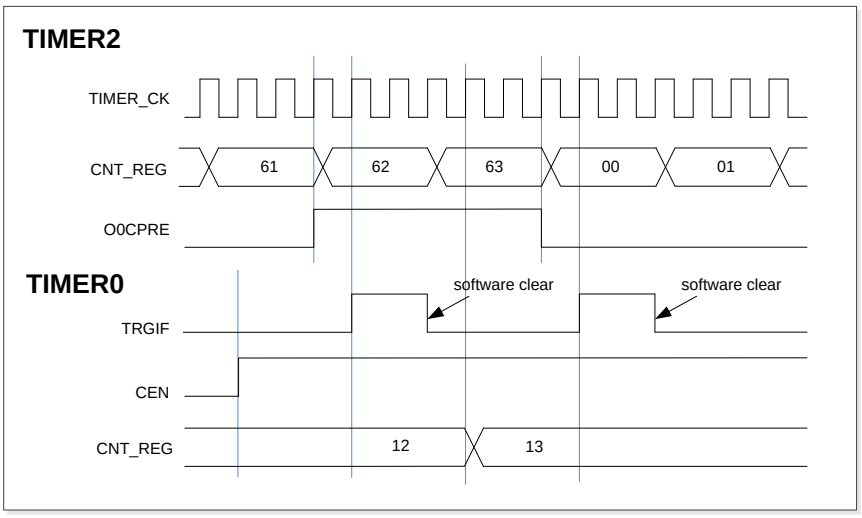
Figure 18-29. Pause TIMER0 with enable signal of TIMER2



In this example, we also can use O0CPRE as trigger source instead of enable signal output. Do as follow:

1. Configure Timer2 in master mode and its output 0 Compare Prepare signal (O0CPRE) as trigger output (MMS=3'b100 in the TIMER2_CTL1 register).
2. Configure the Timer2 O0CPRE waveform (TIMER2_CH0CTL register).
3. Configure Timer0 to get the input trigger from Timer2 (TRGS=3'b010 in the TIMERx_SMCFG register).
4. Configure Timer0 in pause mode (SMC=3'b101 in TIMERx_SMCFG register).
5. Enable Timer0 by writing '1 in the CEN bit (TIMER0_CTL0 register).
6. Start Timer2 by writing '1 in the CEN bit (TIMER2_CTL0 register).

Figure 18-30. Pause TIMER0 with O0CPREF signal of Timer2



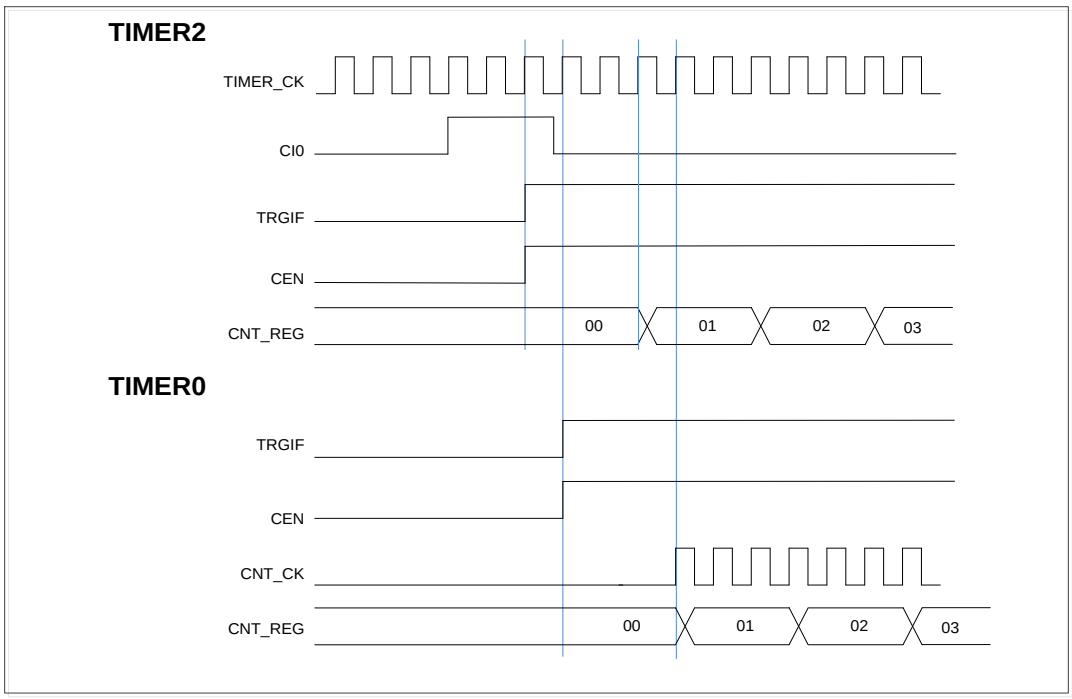
- Using an external trigger to start 2 timers synchronously

We configure the start of Timer0 triggered by the enable signal of Timer2, and Timer2 is triggered by its CI0 input rises edge. To ensure 2 timers start synchronously, Timer2 must be configured in Master/Slave mode. Do as follow:

1. Configure Timer2 in slave mode to get the input trigger from CI0 (TRGS=3'b100 in the TIMER2_SMCFG register).
2. Configure Timer2 in event mode (SMC=3'b110 in the TIMER2_SMCFG register).
3. Configure the Timer2 in Master/Slave mode by writing MSM=1 (TIMER2_SMCFG register).
4. Configure Timer0 to get the input trigger from Timer2 (TRGS=3'b010 in the TIMERx_SMCFG register).
5. Configure Timer0 in event mode (SMC=3'b110 in the TIMER0_SMCFG register).

When a rising edge occurs on Timer2's CI0, two timer's counters start counting synchronously on the internal clock and both TRGIF flags are set.

Figure 18-31. Triggering TIMER0 and TIMER2 with TIMER2's CI0 input



Timer DMA mode

Timer's DMA mode is the function that configures timer's register by DMA module. The relative registers are TIMERx_DMACFG and TIMERx_DMATB. Of course, you have to enable a DMA request which will be asserted by some internal event. When the interrupt event was asserted, TIMERx will send a request to DMA, which is configured to M2P mode and PADDR is TIMERx_DMATB, then DMA will access the TIMERx_DMATB. In fact, register TIMERx_DMATB is only a buffer; timer will map the TIMERx_DMATB to an internal register,

appointed by the field of DMATA in TIMERx_DMACFG. If the field of DMATC in TIMERx_DMACFG is 0(1 transfer), then the timer's DMA request is finished. While if TIMERx_DMATC is not 0, such as 3(4 transfers), then timer will send 3 more requests to DMA, and DMA will access timer's registers DMATA+0x4, DMATA+0x8, DMATA+0xc at the next 3 accesses to TIMERx_DMATB. In one word, one time DMA internal interrupt event assert, DMATC+1 times request will be send by TIMERx.

If one more time DMA request event coming, TIMERx will repeat the process as above.

Timer debug mode

When the Cortex™-M3 halted, and the TIMERx_HOLD configuration bit in DBG_CTL2 register is set to 1, the TIMERx counter stops.

18.1.5. Register definition

TIMER0 start address: 0x4001 2C00

TIMER7 start address: 0x4001 3400

Control register 0 (TIMERx_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CKDIV[1:0]		ARSE	CAM[1:0]		DIR	SPM	UPS	UPDIS	CEN
						rw		rw	rw		rw	rw	rw	rw	rw

Bits	Fields	Descriptions
15:10	Reserved	Must be kept at reset value
9:8	CKDIV[1:0]	Clock division The CKDIV bits can be configured by software to specify division ratio between the timer clock (TIMER_CK) and the dead-time and sampling clock (DTS), which is used by the dead-time generators and the digital filters. 00: $f_{DTS}=f_{TIMER\_CK}$ 01: $f_{DTS}= f_{TIMER\_CK}$ /2 10: $f_{DTS}= f_{TIMER\_CK}$ /4 11: Reserved
7	ARSE	Auto-reload shadow enable 0: The shadow register for TIMERx_CAR register is disabled 1: The shadow register for TIMERx_CAR register is enabled
6:5	CAM[1:0]	Counter aligns mode selection 00: No center-aligned mode (edge-aligned mode). The direction of the counter is specified by the DIR bit. 01: Center-aligned and counting down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting down, compare interrupt flag of channels can be set. 10: Center-aligned and counting up assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting up, compare interrupt flag of channels can be set. 11: Center-aligned and counting up/down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in

		TIMERx_CHCTL0 register). Both when the counter is counting up and counting down, compare interrupt flag of channels can be set. After the counter is enabled, CAM[1:0] cannot be switched from 0x00 to non 0x00.
4	DIR	Direction 0: Count up 1: Count down This bit is read only when the timer is configured in center-aligned mode or encoder mode.
3	SPM	Single pulse mode. 0: Counter continues after update event. 1: The CEN is cleared by hardware and the counter stops at next update event.
2	UPS	Update source This bit is used to select the update event sources by software. 0: Any of the following events generate an update interrupt or DMA request: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: Only counter overflow/underflow generates an update interrupt or DMA request.
1	UPDIS	Update disable. This bit is used to enable or disable the update event generation. 0: update event enable. The update event is generate and the buffered registers are loaded with their preloaded values when one of the following events occurs: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: update event disable. The buffered registers keep their value, while the counter and the prescaler are reinitialized if the UG bit is set or if the slave mode controller generates a hardware reset event.
0	CEN	Counter enable 0: Counter disable 1: Counter enable The CEN bit must be set by software when timer works in external clock, pause mode and encoder mode. While in event mode, the hardware can set the CEN bit automatically.

Control register 1 (TIMERx_CTL1)

Address offset: 0x04

11	ISO1N	Idle state of channel 1 complementary output Refer to ISO0N bit
10	ISO1	Idle state of channel 1 output Refer to ISO0 bit
9	ISO0N	Idle state of channel 0 complementary output 0: When POEN bit is reset, CH0_ON is set low. 1: When POEN bit is reset, CH0_ON is set high This bit can be modified only when PROT [1:0] bits in TIMERx_CCHP register is 00.
8	ISO0	Idle state of channel 0 output 0: When POEN bit is reset, CH0_O is set low. 1: When POEN bit is reset, CH0_O is set high The CH0_O output changes after a dead-time if CH0_ON is implemented. This bit can be modified only when PROT [1:0] bits in TIMERx_CCHP register is 00.
7	TI0S	Channel 0 trigger input selection 0: The TIMERx_CH0 pin input is selected as channel 0 trigger input. 1: The result of combinational XOR of TIMERx_CH0, CH1 and CH2 pins is selected as channel 0 trigger input.
6:4	MMC[2:0]	Master mode control These bits control the selection of TRGO signal, which is sent in master mode to slave timers for synchronization function. 000: Reset. When the UPG bit in the TIMERx_SWEVG register is set or a reset is generated by the slave mode controller, a TRGO pulse occurs. And in the latter case, the signal on TRGO is delayed compared to the actual reset. 001: Enable. This mode is useful to start several timers at the same time or to control a window in which a slave timer is enabled. In this mode the master mode controller selects the counter enable signal as TRGO. The counter enable signal is

		set when CEN control bit is set or the trigger input in pause mode is high. There is a delay between the trigger input in pause mode and the TRGO output, except if the master-slave mode is selected. 010: Update. In this mode the master mode controller selects the update event as TRGO. 011: Capture/compare pulse. In this mode the master mode controller generates a TRGO pulse when a capture or a compare match occurred in channal0. 100: Compare. In this mode the master mode controller selects the O0CPRE signal as TRGO 101: Compare. In this mode the master mode controller selects the O1CPRE signal as TRGO 110: Compare. In this mode the master mode controller selects the O2CPRE signal as TRGO 111: Compare. In this mode the master mode controller selects the O3CPRE signal as TRGO
3	DMAS	DMA request source selection 0: DMA request of channel x is sent when capture/compare event occurs. 1: DMA request of channel x is sent when update event occurs.
2	CCUC	Commutation control shadow register update control When the commutation control shadow enable (for CHxEN, CHxNEN and CHxCOMCTL bits) are set (CCSE=1), these shadow registers update are controlled as below: 0: The shadow registers update when CMTG bit is set. 1: The shadow registers update when CMTG bit is set or a rising edge of TRGI occurs. When a channel does not have a complementary output, this bit has no effect.
1	Reserved	Must be kept at reset value.
0	CCSE	Commutation control shadow enable 0: The shadow registers for CHxEN, CHxNEN and CHxCOMCTL bits are disabled. 1: The shadow registers for CHxEN, CHxNEN and CHxCOMCTL bits are enabled. After these bits have been written, they are updated when commutation event coming. When a channel does not have a complementary output, this bit has no effect.

Slave mode configuration register (TIMERx_SMCFG)

Address offset: 0x08
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	SMC1	ETPSC[1:0]		ETFC[3:0]				MSM	TRGS[2:0]			Reserved	SMC[2:0]		
rw	rw	rw		rw				rw	rw				rw		

Bits	Fields	Descriptions
15	ETP	External trigger polarity This bit specifies the polarity of ETI signal 0: ETI is active at high level or rising edge. 1: ETI is active at low level or falling edge.
14	SMC1	Part of SMC for enable External clock mode1. In external clock mode 1, the counter is clocked by any active edge on the ETIF signal. 0: External clock mode 1 disabled 1: External clock mode 1 enabled. It is possible to simultaneously use external clock mode 1 with the restart mode, pause mode or event mode. But the TRGS bits must not be 3'b111 in this case. The external clock input will be ETIF if external clock mode 0 and external clock mode 1 are enabled at the same time. **Note:** External clock mode 0 enable is in this register's SMC bit-filed.
13:12	ETPSC[1:0]	External trigger prescaler The frequency of external trigger signal ETI can not exceed 1/4 of TIMER_CK frequency. When the external trigger signal is a fast clock, the prescaler can be enabled to reduce ETI frequency. 00: Prescaler disable 01: ETI frequency will be divided by 2 10: ETI frequency will be divided by 4 11: ETI frequency will be divided by 8
11:8	ETFC[3:0]	External trigger filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample ETI signal and the length of the digital filter applied to ETI. 0000: Filter disabled. f_{SAMP}= f_{DTS}, N=1. 0001: f_{SAMP}= f_{TIMER_CK}, N=2. 0010: f_{SAMP}= f_{TIMER_CK}, N=4. 0011: f_{SAMP}= f_{TIMER_CK}, N=8. 0100: f_{SAMP}=f_{DTS}/2, N=6. 0101: f_{SAMP}=f_{DTS}/2, N=8. 0110: f_{SAMP}=f_{DTS}/4, N=6. 0111: f_{SAMP}=f_{DTS}/4, N=8. 1000: f_{SAMP}=f_{DTS}/8, N=6. 1001: f_{SAMP}=f_{DTS}/8, N=8. 1010: f_{SAMP}=f_{DTS}/16, N=5.

		1011: $f_{SAMP}=f_{DTS}/16$, N=6. 1100: $f_{SAMP}=f_{DTS}/16$, N=8. 1101: $f_{SAMP}=f_{DTS}/32$, N=5. 1110: $f_{SAMP}=f_{DTS}/32$, N=6. 1111: $f_{SAMP}=f_{DTS}/32$, N=8.
7	MSM	Master-slave mode This bit can be used to synchronize selected timers to begin counting at the same time. The TRGI is used as the start event, and through TRGO, timers are connected together. 0: Master-slave mode disable 1: Master-slave mode enable
6:4	TRGS[2:0]	Trigger selection This bit-field specifies which signal is selected as the trigger input, which is used to synchronize the counter. 000: Internal trigger input 0 (ITI0) 001: Internal trigger input 1 (ITI1) 010: Internal trigger input 2 (ITI2) 011: Internal trigger input 3 (ITI3) 100: CI0 edge flag (CI0F_ED) 101: channel 0 input Filtered output (CI0FE0) 110: channel 1 input Filtered output (CI1FE1) 111: External trigger input filter output(ETIFP) These bits must not be changed when slave mode is enabled.
3	Reserved	Must be kept at reset value.
2:0	SMC[2:0]	Slave mode control 000: Disable mode. The slave mode is disabled; The prescaler is clocked directly by the internal clock (TIMER_CK) when CEN bit is set high. 001: Quadrature decoder mode 0.The counter counts on CI1FE1 edge, while the direction depends on CI0FE0 level. 010: Quadrature decoder mode 1.The counter counts on CI0FE0 edge, while the direction depends on CI1FE1 level. 011: Quadrature decoder mode 2.The counter counts on both CI0FE0 and CI1FE1 edge, while the direction depends on each other. 100: Restart mode. The counter is reinitialized and the shadow registers are updated on the rising edge of the selected trigger input. 101: Pause mode. The trigger input enables the counter clock when it is high and disables the counter when it is low. 110: Event mode. A rising edge of the trigger input enables the counter. The counter cannot be disabled by the slave mode controller. 111: External clock mode 0. The counter counts on the rising edges of the selected trigger.

DMA and interrupt enable register (TIMERx_DMAINTEN)

Address offset: 0x0C

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

3	CH2IE	Channel 2 capture/compare interrupt enable 0: disabled 1: enabled
2	CH1IE	Channel 1 capture/compare interrupt enable 0: disabled 1: enabled
1	CH0IE	Channel 0 capture/compare interrupt enable 0: disabled 1: enabled
0	UPIE	Update interrupt enable 0: disabled 1: enabled

Interrupt flag register (TIMERx_INTF)

Address offset: 0x10
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			CH3OF	CH2OF	CH1OF	CH0OF	Reserved	BRKIF	TRGIF	CMTIF	CH3IF	CH2IF	CH1IF	CH0IF	UPIF
			rc_w0	rc_w0	rc_w0	rc_w0	.	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0

Bits	Fields	Descriptions
15:13	Reserved	Must be kept at reset value.
12	CH3OF	Channel 3 over capture flag Refer to CH0OF description
11	CH2OF	Channel 2 over capture flag Refer to CH0OF description
10	CH1OF	Channel 1 over capture flag Refer to CH0OF description
9	CH0OF	Channel 0 over capture flag When channel 0 is configured in input mode, this flag is set by hardware when a

		capture event occurs while CH0IF flag has already been set. This flag is cleared by software. 0: No over capture interrupt occurred 1: Over capture interrupt occurred
8	Reserved	Must be kept at reset value.
7	BRKIF	Break interrupt flag This flag is set by hardware when the break input goes active, and cleared by software if the break input is not active. 0: No active level break has been detected. 1: An active level has been detected.
6	TRGIF	Trigger interrupt flag This flag is set by hardware on trigger event and cleared by software. When the slave mode controller is enabled in all modes but pause mode, an active edge on trigger input generates a trigger event. When the slave mode controller is enabled in pause mode both edges on trigger input generates a trigger event. 0: No trigger event occurred. 1: Trigger interrupt occurred.
5	CMTIF	Channel commutation interrupt flag This flag is set by hardware when channel's commutation event occurs, and cleared by software 0: No channel commutation interrupt occurred 1: Channel commutation interrupt occurred
4	CH3IF	Channel 3 's capture/compare interrupt flag Refer to CH0IF description
3	CH2IF	Channel 2 's capture/compare interrupt flag Refer to CH0IF description
2	CH1IF	Channel 1 's capture/compare interrupt flag Refer to CH0IF description
1	CH0IF	Channel 0 's capture/compare interrupt flag This flag is set by hardware and cleared by software. When channel 0 is in input mode, this flag is set when a capture event occurs. When channel 0 is in output mode, this flag is set when a compare event occurs. 0: No Channel 0 interrupt occurred 1: Channel 0 interrupt occurred
0	UPIF	Update interrupt flag This bit is set by hardware on an update event and cleared by software. 0: No update interrupt occurred 1: Update interrupt occurred

Software event generation register (TIMERx_SWEVG)

Address offset: 0x14

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								BRKG	TRGG	CMTG	CH3G	CH2G	CH1G	CH0G	UPG
								w	w	w	w	w	w	w	w

Bits	Fields	Descriptions
15:8	Reserved	Must be kept at reset value.
7	BRKG	Break event generation This bit is set by software and cleared by hardware automatically. When this bit is set, the POEN bit is cleared and BRKIF flag is set, related interrupt or DMA transfer can occur if enabled. 0: No generate a break event 1: Generate a break event
6	TRGG	Trigger event generation This bit is set by software and cleared by hardware automatically. When this bit is set, the TRGIF flag in TIMERx_INTF register is set, related interrupt or DMA transfer can occur if enabled. 0: No generate a trigger event 1: Generate a trigger event
5	CMTG	Channel commutation event generation This bit is set by software and cleared by hardware automatically. When this bit is set, channel's capture/compare control registers (CHxEN, CHxNEN and CHxCOMCTL bits) are updated based on the value of CCSE (in the TIMERx_CTL1). 0: No affect 1: Generate channel's c/c control update event
4	CH3G	Channel 3's capture or compare event generation Refer to CH0G description
3	CH2G	Channel 2's capture or compare event generation Refer to CH0G description
2	CH1G	Channel 1's capture or compare event generation Refer to CH0G description
1	CH0G	Channel 0's capture or compare event generation This bit is set by software in order to generate a capture or compare event in channel 0, it is automatically cleared by hardware. When this bit is set, the CH0IF

		flag is set, the corresponding interrupt or DMA request is sent if enabled. In addition, if channel 1 is configured in input mode, the current value of the counter is captured in TIMERx_CH0CV register, and the CH0OF flag is set if the CH0IF flag was already high. 0: No generate a channel 1 capture or compare event 1: Generate a channel 1 capture or compare event
0	UPG	Update event generation This bit can be set by software, and cleared by hardware automatically. When this bit is set, the counter is cleared if the center-aligned or up counting mode is selected, else (down counting) it takes the auto-reload value. The prescaler counter is cleared at the same time. 0: No generate an update event 1: Generate an update event

Channel control register 0 (TIMERx_CHCTL0)

Address offset: 0x18
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH1COMCEN	CH1COMCTL[2:0]			CH1COMSEN	CH1COMFEN	CH1MS[1:0]		CH0COMCEN	CH0COMCTL[2:0]			CH0COMSEN	CH0COMFEN	CH0MS[1:0]

rw				rw		rw		rw				rw		rw	

Output compare mode:

Bits	Fields	Descriptions
15	CH1COMCEN	Channel 1 output compare clear enable Refer to CH0COMCEN description
14:12	CH1COMCTL[2:0]	Channel 1 compare output control Refer to CH0COMCTL description
11	CH1COMSEN	Channel 1 output compare shadow enable Refer to CH0COMSEN description
10	CH1COMFEN	Channel 1 output compare fast enable Refer to CH0COMSEN description
9:8	CH1MS[1:0]	Channel 1 mode selection This bit-field specifies the direction of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH1EN bit in TIMERx_CHCTL2 register is reset). 00: Channel 1 is configured as output 01: Channel 1 is configured as input, IS1 is connected to CI1FE1

		10: Channel 1 is configured as input, IS1 is connected to CI0FE1 11: Channel 1 is configured as input, IS1 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.
7	CH0COMCEN	Channel 0 output compare clear enable. When this bit is set, the O0CPRE signal is cleared when High level is detected on ETIF input. 0: Channel 0 output compare clear disable 1: Channel 0 output compare clear enable
6:4	CH0COMCTL[2:0]	Channel 0 compare output control This bit-field controls the behavior of the output reference signal O0CPRE which drives CH0_O and CH0_ON. O0CPRE is active high, while CH0_O and CH0_ON active level depends on CH0P and CH0NP bits. 000: Frozen. The O0CPRE signal keeps stable, independent of the comparison between the register TIMERx_CH0CV and the counter TIMERx_CNT. 001: Set the channel output. O0CPRE signal is forced high when the counter matches the output compare register TIMERx_CH0CV. 010: Clear the channel output. O0CPRE signal is forced low when the counter matches the output compare register TIMERx_CH0CV. 011: Toggle on match. O0CPRE toggles when the counter matches the output compare register TIMERx_CH0CV. 100: Force low. O0CPRE is forced low level. 101: Force high. O0CPRE is forced high level. 110: PWM mode0. When counting up, O0CPRE is high as long as the counter is smaller than TIMERx_CH0CV,otherwise it is low. When counting down, O0CPRE is low as long as the counter is larger than TIMERx_CH0CV, otherwise it is high. 111: PWM mode1. When counting up, O0CPRE is low as long as the counter is smaller than TIMERx_CH0CV, otherwise it is high. When counting down, O0CPRE is high as long as the counter is larger than TIMERx_CH0CV, otherwise it is low. When configured in PWM mode, the O0CPRE level changes only when the output compare mode switches from “frozen” mode to “PWM” mode or when the result of the comparison changes. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00(COMPARE MODE).
3	CH0COMSEN	Channel 0 compare output shadow enable When this bit is set, the shadow register of TIMERx_CH0CV register, which updates at each update event, will be enabled. 0: Channel 0 output compare shadow disable 1: Channel 0 output compare shadow enable The PWM mode can be used without validating the shadow register only in single pulse mode (SPM bit in TIMERx_CTL0 register is set).

		This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00.
2	CH0COMFEN	Channel 0 output compare fast enable When this bit is set, the effect of an event on the trigger in input on the capture/compare output will be accelerated if the channel is configured in PWM0 or PWM1 mode. The output channel will treat an active edge on the trigger input as a compare match, and CH0_O is set to the compare level independently from the result of the comparison. 0: Channel 0 output quickly compare disable. The minimum delay from an edge on the trigger input to activate CH0_O output is 5 clock cycles. 1: Channel 0 output quickly compare enable. The minimum delay from an edge on the trigger input to activate CH0_O output is 3 clock cycles.
1:0	CH0MS[1:0]	Channel 0 I/O mode selection This bit-field specifies the work mode of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH0EN bit in TIMERx_CHCTL2 register is reset).). 00: Channel 0 is configured as output 01: Channel 0 is configured as input, IS0 is connected to CI0FE0 10: Channel 0 is configured as input, IS0 is connected to CI1FE0 11: Channel 0 is configured as input, IS0 is connected to ITS, This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.

Input capture mode:

Bits	Fields	Descriptions
15:12	CH1CAPFLT[3:0]	Channel 1 input capture filter control Refer to CH0CAPFLT description
11:10	CH1CAPPSC[1:0]	Channel 1 input capture prescaler Refer to CH0CAPPSC description
9:8	CH1MS[1:0]	Channel 1 mode selection Same as Output compare mode
7:4	CH0CAPFLT[3:0]	Channel 0 input capture filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample CI0 input signal and the length of the digital filter applied to CI0. 0000: Filter disabled, $f_{SAMP}=f_{DTS}$, N=1 0001: $f_{SAMP}=f_{TIMER\_CK}$, N=2 0010: $f_{SAMP}= f_{TIMER\_CK}$, N=4 0011: $f_{SAMP}= f_{TIMER\_CK}$, N=8 0100: $f_{SAMP}=f_{DTS}/2$, N=6 0101: $f_{SAMP}=f_{DTS}/2$, N=8

		0110: $f_{SAMP}=f_{DTS}/4$, N=6 0111: $f_{SAMP}=f_{DTS}/4$, N=8 1000: $f_{SAMP}=f_{DTS}/8$, N=6 1001: $f_{SAMP}=f_{DTS}/8$, N=8 1010: $f_{SAMP}=f_{DTS}/16$, N=5 1011: $f_{SAMP}=f_{DTS}/16$, N=6 1100: $f_{SAMP}=f_{DTS}/16$, N=8 1101: $f_{SAMP}=f_{DTS}/32$, N=5 1110: $f_{SAMP}=f_{DTS}/32$, N=6 1111: $f_{SAMP}=f_{DTS}/32$, N=8
3:2	CH0CAPPSC[1:0]	Channel 0 input capture prescaler This bit-field specifies the factor of the prescaler on channel 0 input. The prescaler is reset when CH0EN bit in TIMERx_CHCTL2 register is clear. 00: Prescaler disable, capture is done on each channel input edge 01: Capture is done every 2 channel input edges 10: Capture is done every 4channel input edges 11: Capture is done every 8 channel input edges
1:0	CH0MS[1:0]	Channel 0 mode selection Same as Output compare mode

Channel control register 1 (TIMERx_CHCTL1)

Address offset: 0x1C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Output compare mode:

Bits	Fields	Descriptions
15	CH3COMCEN	Channel 3 output compare clear enable Refer to CH0COMCEN description
14:12	CH3COMCTL[2:0]	Channel 3 compare output control Refer to CH0COMCTL description
11	CH3COMSEN	Channel 3 output compare shadow enable Refer to CH0COMSEN description
10	CH3COMFEN	Channel 3 output compare fast enable

		Refer to CH0COMSEN description
9:8	CH3MS[1:0]	Channel 3 mode selection This bit-field specifies the direction of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH3EN bit in TIMERx_CHCTL2 register is reset). 00: Channel 3 is configured as output 01: Channel 3 is configured as input, IS3 is connected to CI3FE3 10: Channel 3 is configured as input, IS3 is connected to CI2FE3 11: Channel 3 is configured as input, IS3 is connected to ITS, This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.
7	CH2COMCEN	Channel 2 output compare clear enable. When this bit is set, the O2CPRE signal is cleared when High level is detected on ETIF input. 0: Channel 2 output compare clear disable 1: Channel 2 output compare clear enable
6:4	CH2COMCTL[2:0]	Channel 2 compare output control This bit-field controls the behavior of the output reference signal O2CPRE which drives CH2_O and CH2_ON. O2CPRE is active high, while CH2_O and CH2_ON active level depends on CH2P and CH2NP bits. 000: Frozen. The O2CPRE signal keeps stable, independent of the comparison between the output compare register TIMERx_CH2CV and the counter TIMERx_CNT. 001: Set high on match. O2CPRE signal is forced high when the counter matches the output compare register TIMERx_CH2CV. 010: Set low on match. O2CPRE signal is forced low when the counter matches the output compare register TIMERx_CH2CV. 011: Toggle on match. O2CPRE toggles when the counter matches the output compare register TIMERx_CH2CV. 100: Force low. O2CPRE is forced low level. 101: Force high. O2CPRE is forced high level. 110: PWM mode 0. When counting up, O2CPRE is high as long as the counter is smaller than TIMERx_CH2CV else low. When counting down, O2CPRE is low as long as the counter is larger than TIMERx_CH2CV else high. 111: PWM mode 1. When counting up, O2CPRE is low as long as the counter is smaller than TIMERx_CH2CV else high. When counting down, O2CPRE is high as long as the counter is larger than TIMERx_CH2CV else low. When configured in PWM mode, the O2CPRE level changes only when the output compare mode switches from “frozen” mode to “PWM” mode or when the result of the comparison changes. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH2MS bit-filed is 00(COMPARE MODE).

3	CH2COMSEN	Channel 2 compare output shadow enable When this bit is set, the shadow register of TIMERx_CH2CV register, which updates at each update event will be enabled. 0: Channel 2 output compare shadow disable 1: Channel 2 output compare shadow enable The PWM mode can be used without validating the shadow register only in single pulse mode (SPM bit in TIMERx_CTL0 register is set). This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00.
2	CH2COMFEN	Channel 2 output compare fast enable When this bit is set, the effect of an event on the trigger in input on the capture/compare output will be accelerated if the channel is configured in PWM1 or PWM2 mode. The output channel will treat an active edge on the trigger input as a compare match, and CH2_O is set to the compare level independently from the result of the comparison. 0: Channel 2 output quickly compare disable. The minimum delay from an edge on the trigger input to activate CH2_O output is 5 clock cycles. 1: Channel 2 output quickly compare enable. The minimum delay from an edge on the trigger input to activate CH2_O output is 3 clock cycles.
1:0	CH2MS[1:0]	Channel 2 I/O mode selection This bit-field specifies the work mode of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH2EN bit in TIMERx_CHCTL2 register is reset).). 00: Channel 2 is configured as output 01: Channel 2 is configured as input, IS2 is connected to CI2FE2 10: Channel 2 is configured as input, IS2 is connected to CI3FE2 11: Channel 2 is configured as input, IS2 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.

Input capture mode:

Bits	Fields	Descriptions
15:12	CH3CAPFLT[3:0]	Channel 3 input capture filter control Refer to CH0CAPFLT description
11:10	CH3CAPPSC[1:0]	Channel 3 input capture prescaler Refer to CH0CAPPSC description
9:8	CH3MS[1:0]	Channel 3 mode selection Same as Output compare mode
7:4	CH2CAPFLT[3:0]	Channel 2 input capture filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample

		CI2 input signal and the length of the digital filter applied to CI2. 0000: Filter disable, $f_{SAMP}=f_{DTS}$, N=1 0001: $f_{SAMP}=f_{TIMER\_CK}$, N=2 0010: $f_{SAMP}= f_{TIMER\_CK}$, N=4 0011: $f_{SAMP}= f_{TIMER\_CK}$, N=8 0100: $f_{SAMP}=f_{DTS}/2$, N=6 0101: $f_{SAMP}=f_{DTS}/2$, N=8 0110: $f_{SAMP}=f_{DTS}/4$, N=6 0111: $f_{SAMP}=f_{DTS}/4$, N=8 1000: $f_{SAMP}=f_{DTS}/8$, N=6 1001: $f_{SAMP}=f_{DTS}/8$, N=8 1010: $f_{SAMP}=f_{DTS}/16$, N=5 1011: $f_{SAMP}=f_{DTS}/16$, N=6 1100: $f_{SAMP}=f_{DTS}/16$, N=8 1101: $f_{SAMP}=f_{DTS}/32$, N=5 1110: $f_{SAMP}=f_{DTS}/32$, N=6 1111: $f_{SAMP}=f_{DTS}/32$, N=8
3:2	CH2CAPPSC[1:0]	Channel 2 input capture prescaler This bit-field specifies the factor of the prescaler on channel 2 input. The prescaler is reset when CH2EN bit in TIMERx_CHCTL2 register is clear. 00: Prescaler disable, capture is done on each channel input edge 01: Capture is done every 2 channel input edges 10: Capture is done every 4 channel input edges 11: Capture is done every 8 channel input edges
1:0	CH2MS[1:0]	Channel 2 mode selection Same as Output compare mode

Channel control register 2 (TIMERx_CHCTL2)

Address offset: 0x20
Reset value: 0x0000

This register can be accessed by half-word(16-bit) or word(32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7	CH1NP	Channel 1 complementary output polarity Refer to CH0NP description
6	CH1NEN	Channel 1 complementary output enable Refer to CH0NEN description
5	CH1P	Channel 1 capture/compare function polarity Refer to CH0P description
4	CH1EN	Channel 1 capture/compare function enable Refer to CH0EN description
3	CH0NP	Channel 0 complementary output polarity When channel 0 is configured in output mode, this bit specifies the complementary output signal polarity. 0: Channel 0 active high 1: Channel 0 active low When channel 0 is configured in input mode, In conjunction with CH0P, this bit is used to define the polarity of CI0. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 or 10.
2	CH0NEN	Channel 0 complementary output enable When channel 0 is configured in output mode, setting this bit enables the complementary output in channel0. 0: Channel 0 complementary output disabled 1: Channel 0 complementary output enabled
1	CH0P	Channel 0 capture/compare function polarity When channel 0 is configured in output mode, this bit specifies the output signal polarity. 0: Channel 0 active high 1: Channel 0 active low When channel 0 is configured in input mode, this bit specifies the CI0 signal

		polarity. [CH0NP, CH0P] will select the active trigger or capture polarity for CI0FE0 or CI1FE0. [CH0NP==0, CH0P==0]: CIxFE0's rising edge is the active signal for capture or trigger operation in slave mode. And CIxFE0 will not be inverted. [CH0NP==0, CH0P==1]: CIxFE0's falling edge is the active signal for capture or trigger operation in slave mode. And CIxFE0 will be inverted. [CH0NP==1, CH0P==0]: Reserved. [CH0NP==1, CH0P==1]: CIxFE0's falling and rising edge are both the active signal for capture or trigger operation in slave mode. And CIxFE0 will be not inverted. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 or 10.
0	CH0EN	Channel 0 capture/compare function enable When channel 0 is configured in output mode, setting this bit enables CH0_O signal in active state. When channel 0 is configured in input mode, setting this bit enables the capture event in channel0. 0: Channel 0 disabled 1: Channel 0 enabled

Counter register (TIMERx_CNT)

Address offset: 0x24
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CNT[15:0]	This bit-filed indicates the current counter value. Writing to this bit-filed can change the value of the counter.

Prescaler register (TIMERx_PSC)

Address offset: 0x28
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

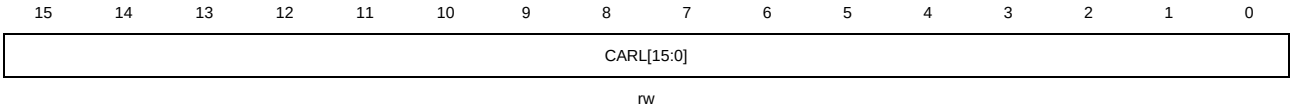
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw															

Bits	Fields	Descriptions
15:0	PSC[15:0]	Prescaler value of the counter clock The PSC clock is divided by (PSC+1) to generate the counter clock. The value of this bit-filed will be loaded to the corresponding shadow register at every update event.

Counter auto reload register (TIMERx_CAR)

Address offset: 0x2C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

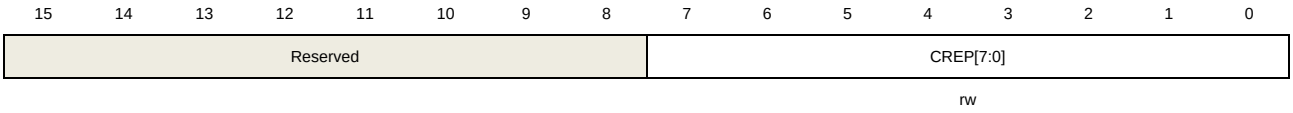


Bits	Fields	Descriptions
15:0	CARL[15:0]	Counter auto reload value This bit-filed specifies the auto reload value of the counter.

Counter repetition register (TIMERx_CREP)

Address offset: 0x30
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:8	Reserved	Must be kept at reset value.
7:0	CREP[7:0]	Counter repetition value This bit-filed specifies the update event generation rate. Each time the repetition counter counting down to zero, an update event is generated. The update rate of the shadow registers is also affected by this bit-filed when these shadow registers are enabled.

Channel 0 capture/compare value register (TIMERx_CH0CV)

Address offset: 0x34
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH0VAL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CH0VAL[15:0]	Capture or compare value of channel0 When channel 0 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 0 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 1 capture/compare value register (TIMERx_CH1CV)

Address offset: 0x38
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH1VAL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CH1VAL[15:0]	Capture or compare value of channel1 When channel 1 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 1 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 2 capture/compare value register (TIMERx_CH2CV)

Address offset: 0x3C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH2VAL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CH2VAL[15:0]	Capture or compare value of channel 2

When channel 2 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only.
When channel 2 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 3 capture/compare value register (TIMERx_CH3CV)

Address offset: 0x40
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH3VAL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CH3VAL[15:0]	Capture or compare value of channel 3 When channel3 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 3 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Complementary channel protection register (TIMERx_CCHP)

Address offset: 0x44
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POEN	OAEN	BRKP	BRKEN	ROS	IOS	PROT[1:0]		DTCFG[7:0]							
rw	rw	rw	rw	rw	rw	rw		rw							

Bits	Fields	Descriptions
15	POEN	Primary output enable This bit s set by software or automatically by hardware depending on the OAEN bit. It is cleared asynchronously by hardware as soon as the break input is active. When one of channels is configured in output mode, setting this bit enables the channel outputs (CHx_O and CHx_ON) if the corresponding enable bits (CHxEN, CHxNEN in TIMERx_CHCTL2 register) have been set. 0: Channel outputs are disabled or forced to idle state. 1: Channel outputs are enabled.

14	OAEN	Output automatic enable This bit specifies whether the POEN bit can be set automatically by hardware. 0: POEN can be not set by hardware. 1: POEN can be set by hardware automatically at the next update event, if the break input is not active. This bit can be modified only when PROT [1:0] bit-filed in TIMERx_CCHP register is 00.
13	BRKP	Break polarity This bit specifies the polarity of the BRKIN input signal. 0: BRKIN input active low 1; BRKIN input active high
12	BRKEN	Break enable This bit can be set to enable the BRKIN and CCS clock failure event inputs. 0: Break inputs disabled 1; Break inputs enabled This bit can be modified only when PROT [1:0] bit-filed in TIMERx_CCHP register is 00.
11	ROS	Run mode off-state configure When POEN bit is set, this bit specifies the output state for the channels which has a complementary output and has been configured in output mode. 0: When POEN bit is set, the channel output signals (CHx_O/CHx_ON) are disabled. 1: When POEN bit is set, the channel output signals (CHx_O/CHx_ON) are enabled, with relationship to CHxEN/CHxNEN bits in TIMERx_CHCTL2 register. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 10 or 11.
10	IOS	Idle mode off-state configure When POEN bit is reset, this bit specifies the output state for the channels which has been configured in output mode. 0: When POEN bit is reset, the channel output signals (CHx_O/CHx_ON) are disabled. 1: When POEN bit is reset, he channel output signals (CHx_O/CHx_ON) are enabled, with relationship to CHxEN/CHxNEN bits in TIMERx_CHCTL2 register. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 10 or 11.
9:8	PROT[1:0]	Complementary register protect control This bit-filed specifies the write protection property of registers. 00: protect disable. No write protection. 01: PROT mode 0.The ISOx/ISOxN bits in TIMERx_CTL1 register and the BRKEN/BRKP/OAEN/DTCFG bits in TIMERx_CCHP register are writing protected.

		10: PROT mode 1. In addition of the registers in PROT mode 0, the CHxP/CHxNP bits in TIMERx_CHCTL2 register (if related channel is configured in output mode) and the ROS/IOS bits in TIMERx_CCHP register are writing protected. 11: PROT mode 2. In addition of the registers in PROT mode 1, the CHxCOMCTL/ CHxCOMSEN bits in TIMERx_CHCTL0/1 registers (if the related channel is configured in output) are writing protected. This bit-field can be written only once after the reset. Once the TIMERx_CCHP register has been written, this bit-field will be writing protected.
7:0	DTCFG[7:0]	Dead time configure This bit-field controls the value of the dead-time, which is inserted before the output transitions. The relationship between DTCFG value and the duration of dead-time is as follow: DTCFG [7:5] =3'b0xx: DTvalue = DTCFG [7:0] * t_{DT}, t_{DT} = t_{DTS}. DTCFG [7:5] =3'b10x: DTvalue = (64+DTCFG [5:0]) * t_{DT}, t_{DT} = t_{DTS} * 2. DTCFG [7:5] =3'b110: DTvalue = (32+DTCFG [4:0]) * t_{DT}, t_{DT} = t_{DTS} * 8. DTCFG [7:5] =3'b111: DTvalue = (32+DTCFG [4:0]) * t_{DT}, t_{DT} = t_{DTS} * 16. This bit can be modified only when PROT [1:0] bit-filed in TIMERx_CCHP register is 00.

DMA configuration register (TIMERx_DMACFG)

Address offset: 0x48
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			DMATC[4:0]					Reserved			DMATA [4:0]				
			rw								rw				

Bits	Fields	Descriptions
15:14	Reserved	Must be kept at reset value.
12:8	DMATC [4:0]	DMA transfer count This filed is defined the number of DMA will access(R/W) the register of TIMERx_DMATB
7:5	Reserved	Must be kept at reset value.
4:0	DMATA [4:0]	DMA transfer access start address This filed define the first address for the DMA access the TIMERx_DMATB. When access is done through the TIMERx_DMA address first time, this bit-field specifies the address you just access. And then the second access to the TIMERx_DMATB, you will access the address of start address + 0x4. 5'b0_0000: TIMERx_CTL0

5’b0_0001: TIMERx_CTL1

…

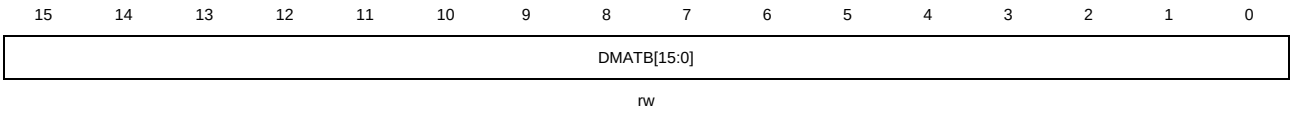
In a word: Start Address = TIMERx_CTL0 + DMATA*4

DMA transfer buffer register (TIMERx_DMATB)

Address offset: 0x4C

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:0	DMATB[15:0]	DMA transfer buffer When a read or write operation is assigned to this register, the register located at the address range (Start Addr + Transfer Timer* 4) will be accessed. The transfer Timer is calculated by hardware, and ranges from 0 to DMATC.

18.2. General level0 timer (TIMERx, x=1, 2, 3, 4)

18.2.1. Overview

The general level0 timer module (Timer1, 2, 3, 4) is a four-channel timer that supports input capture, output compare. They can generate PWM signals to control motor or be used for power management applications. The general level0 time reference is a 16-bit or 32-bit counter that can be used as an unsigned counter.

In addition, the general level0 timers can be programmed and be used to count or time external events that drive other timers.

Timer and timer are completely independent, but there may be synchronized to provide a larger timer with their counters incrementing in unison.

18.2.2. Characteristics

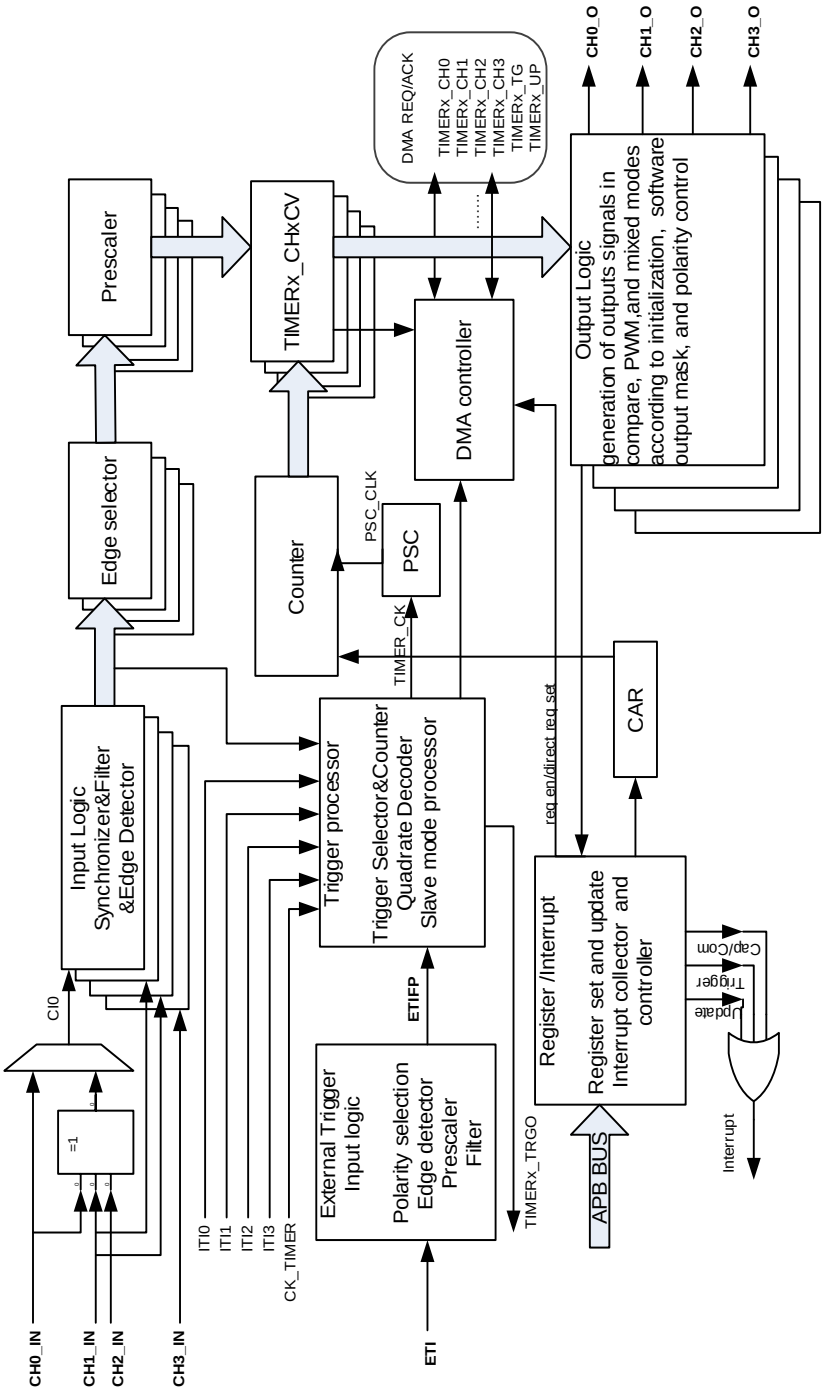
- Total channel num: 4.
- Counter width: 16bit.
- Source of count clock is selectable:
  internal clock, internal trigger, external input, external trigger.
- Multiple counter modes: count up, count down, count up/down.
- Quadrature decoder: used to track motion and determine both rotation direction and position.
- Hall sensor: for 3-phase motor control.
- Programmable prescaler: 16 bit. Factor can be changed on the go.
- Each channel is user-configurable:
  Input capture mode, output compare mode, programmable PWM mode, single pulse mode
- Auto-reload function.
- Interrupt output or DMA request on: update, trigger event, and compare/capture event.
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events.
- Timer synchronization allows selected timers to start counting on the same clock cycle.
- Timer Master/Slave mode controller.

18.2.3. Block diagram

Figure 18-32. General Level 0 timer block diagram provides details on the internal

configuration of the general level0 timer.

Figure 18-32. General Level 0 timer block diagram



18.2.4. Function overview

Clock selection

The general level0 TIMER has the capability of being clocked by either the CK_TIMER or an alternate clock source controlled by SMC (TIMERx_SMCFG bit [2:0]).

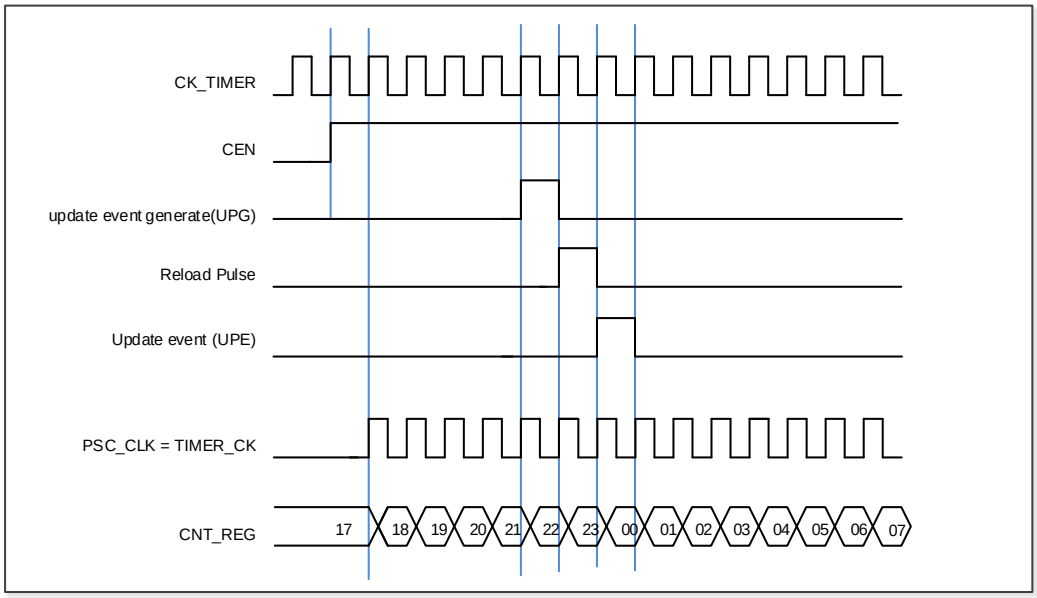
- SMC [2:0] == 3'b000. Internal timer clock CK_TIMER which is from module RCU.

The default internal clock source is the CK_TIMER used to drive the counter prescaler when the slave mode is disabled (SMC [2:0] == 3'b000). When the CEN is set, the CK_TIMER will be divided by PSC value to generate PSC_CLK.

In this mode, the TIMER_CK, driven counter's prescaler to count, is equal to CK_TIMER which is from RCU.

If the slave mode controller is enabled by setting SMC [2:0] in the TIMERx_SMCFG register to an available value including 0x1, 0x2, 0x3 and 0x7, the prescaler is clocked by other clock sources selected by the TRGS [2:0] in the TIMERx_SMCFG register and described as follows. When the slave mode selection bits SMC [2:0] are set to 0x4, 0x5 or 0x6, the internal clock TIMER_CK is the counter prescaler driving clock source.

Figure 18-33. Normal mode, internal clock divided by 1



- SMC [2:0] == 3'b111 (external clock mode 0). External input pin source

The TIMER_CK, driven counter's prescaler to count, can be triggered by the event of rising or falling edge on the external pin TIMERx_CI0/TIMERx_CI1. This mode can be selected by setting SMC [2:0] to 0x7 and the TRGS [2:0] to 0x4, 0x5 or 0x6.

And, the counter prescaler can also be driven by rising edge on the internal trigger input pin ITI0/1/2/3. This mode can be selected by setting SMC [2:0] to 0x7 and the TRGS [2:0] to 0x0,

0x1, 0x2 or 0x3.

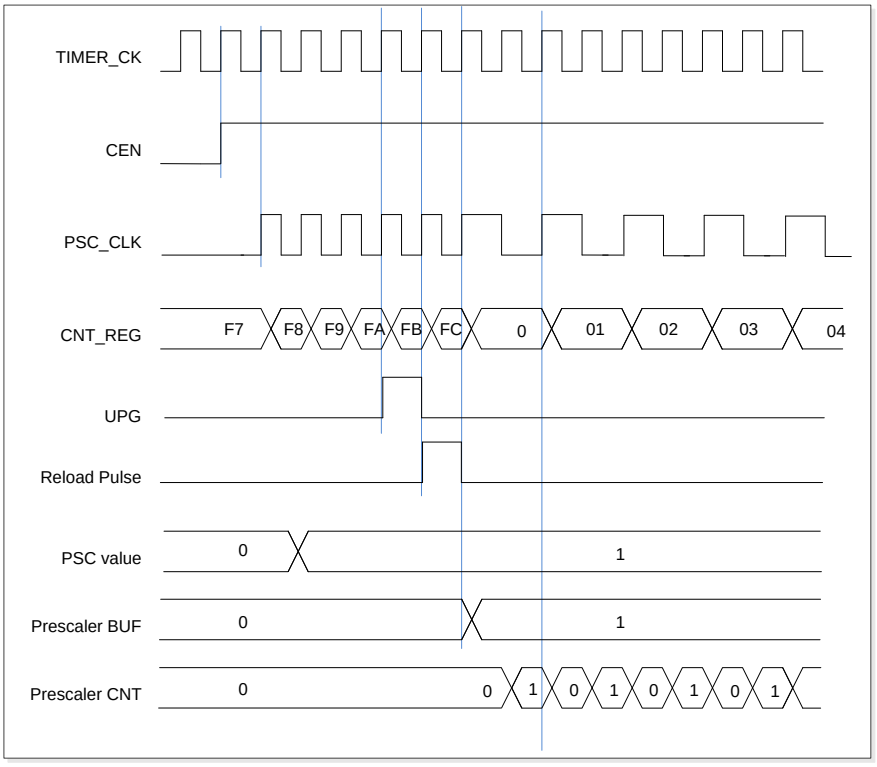
- SMC1== 1'b1 (external clock mode 1). External input pin source (ETI)

The TIMER_CK, driven counter's prescaler to count, can be triggered by the event of rising or falling edge on the external pin ETI. This mode can be selected by setting the SMC1 bit in the TIMERx_SMCFG register to 1. The other way to select the ETI signal as the clock source is set the SMC [2:0] to 0x7 and the TRGS [2:0] to 0x7 respectively. Note that the ETI signal is derived from the ETI pin sampled by a digital filter. When the clock source is selected to come from the ETI signal, the trigger controller including the edge detection circuitry will generate a clock pulse during each ETI signal rising edge to clock the counter prescaler.

Prescaler

The prescaler can divide the timer clock (TIMER_CK) to the counter clock (PSC_CLK by any factor between 1 and 65536. It is controlled through prescaler register (TIMERx_PSC) which can be changed on the go but be taken into account at the next update event.

Figure 18-34. Counter timing diagram with prescaler division change from 1 to 2



Up counting mode

In this mode, the counter counts up continuously from 0 to the counter-reload value, which is defined in the TIMERx_CAR register, in a count-up direction. Once the counter reaches the counter reload value, the counter restarts to count once again from 0. The update event is generated at each counter overflow. The counting direction bit DIR in the TIMERx_CTL1 register should be set to 0 for the up counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to 0 and generates an update event.

If the UPDIS bit in TIMERx_CTL0 register is set, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior for different clock prescaler factor when TIMERx_CAR=0x63.

Figure 18-35. Up-counter timechart, PSC=0/1

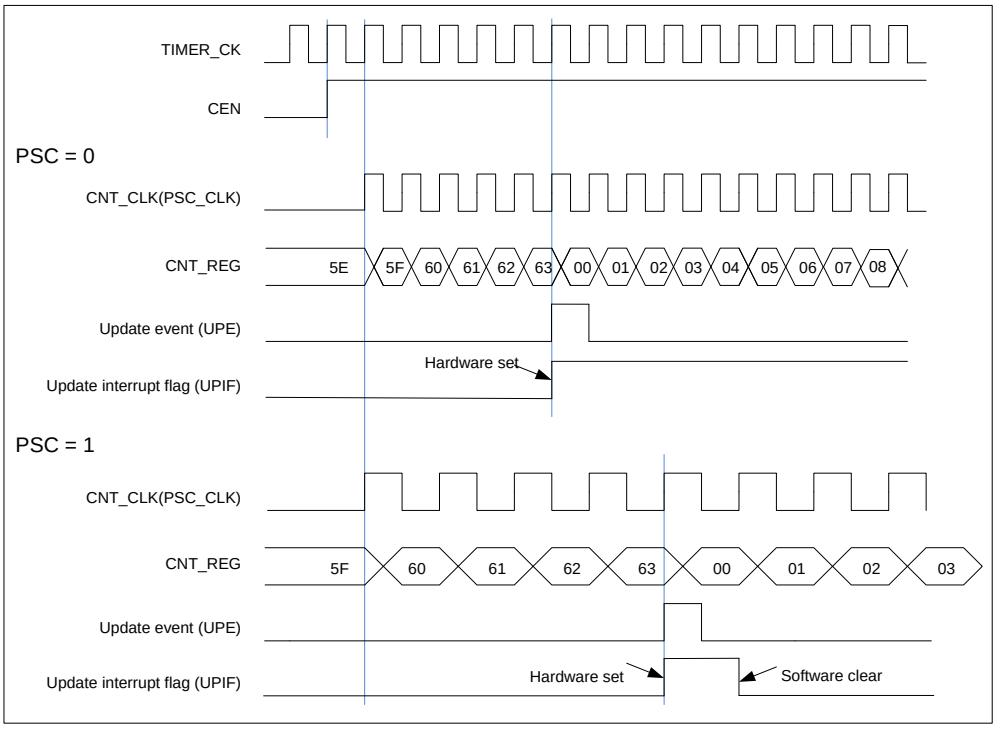


Figure 18-36. Up-counter timechart, change TIMERx_CAR on the go.

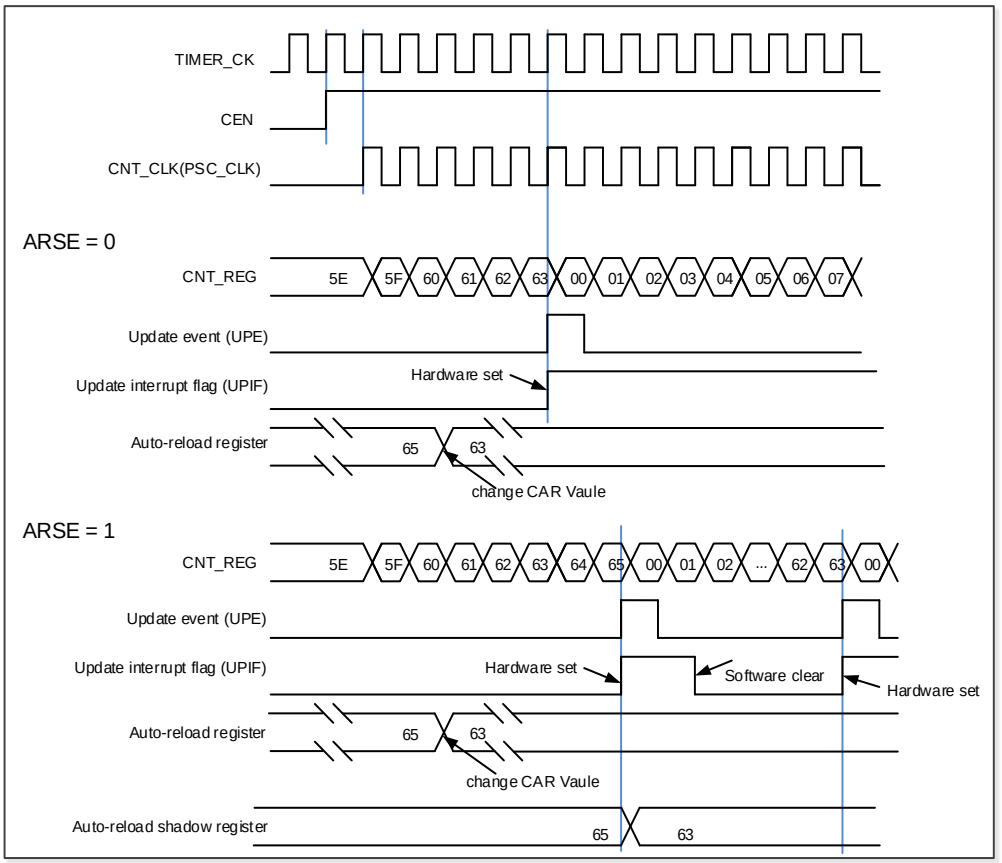

Down counting mode

In this mode, the counter counts down continuously from the counter-reload value, which is defined in the TIMERx_CAR register, to 0 in a count-down direction. Once the counter reaches to 0, the counter restarts to count again from the counter-reload value. If the repetition counter is set, the update event was generated after the number (TIMERx_CREP+1) of underflow. Else the update event is generated at each counter underflow. The counting direction bit DIR in the TIMERx_CTL0 register should be set to 1 for the down-counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to the counter-reload value and generates an update event.

If the UPDIS bit in TIMERx_CTL0 register is set, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior for different clock frequencies when TIMERx_CAR=0x63.

Figure 18-37. Down-counter timechart, PSC=0/1

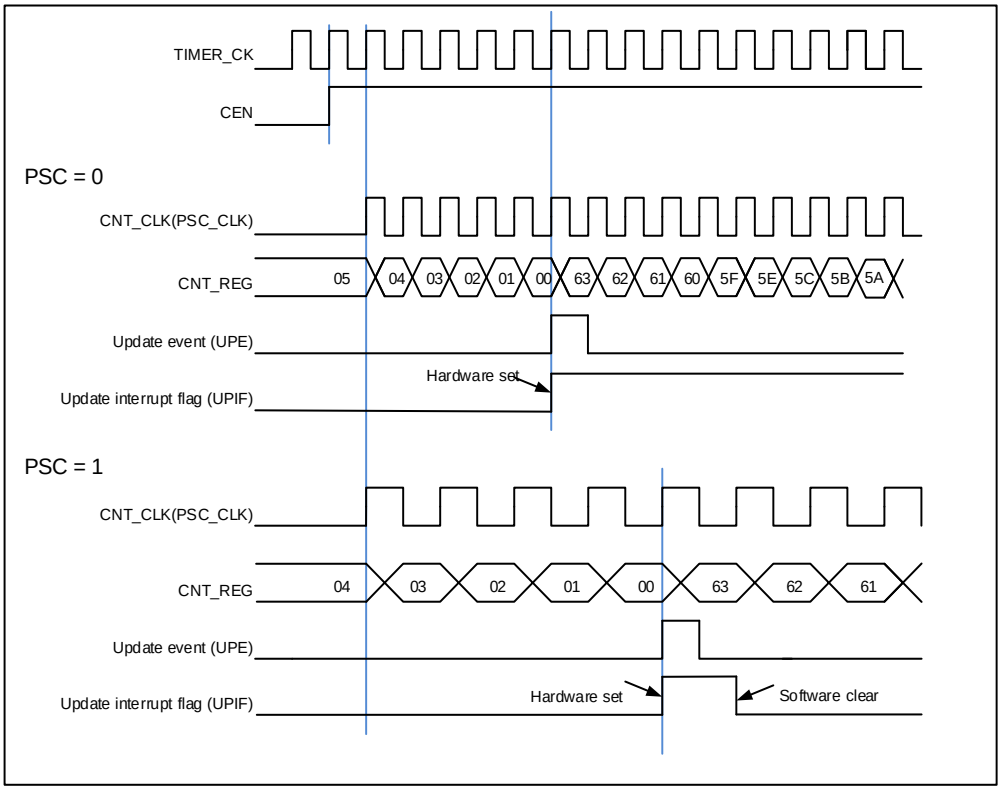

Figure 18-38. Down-counter timechart, change TIMERx_CAR on the go.

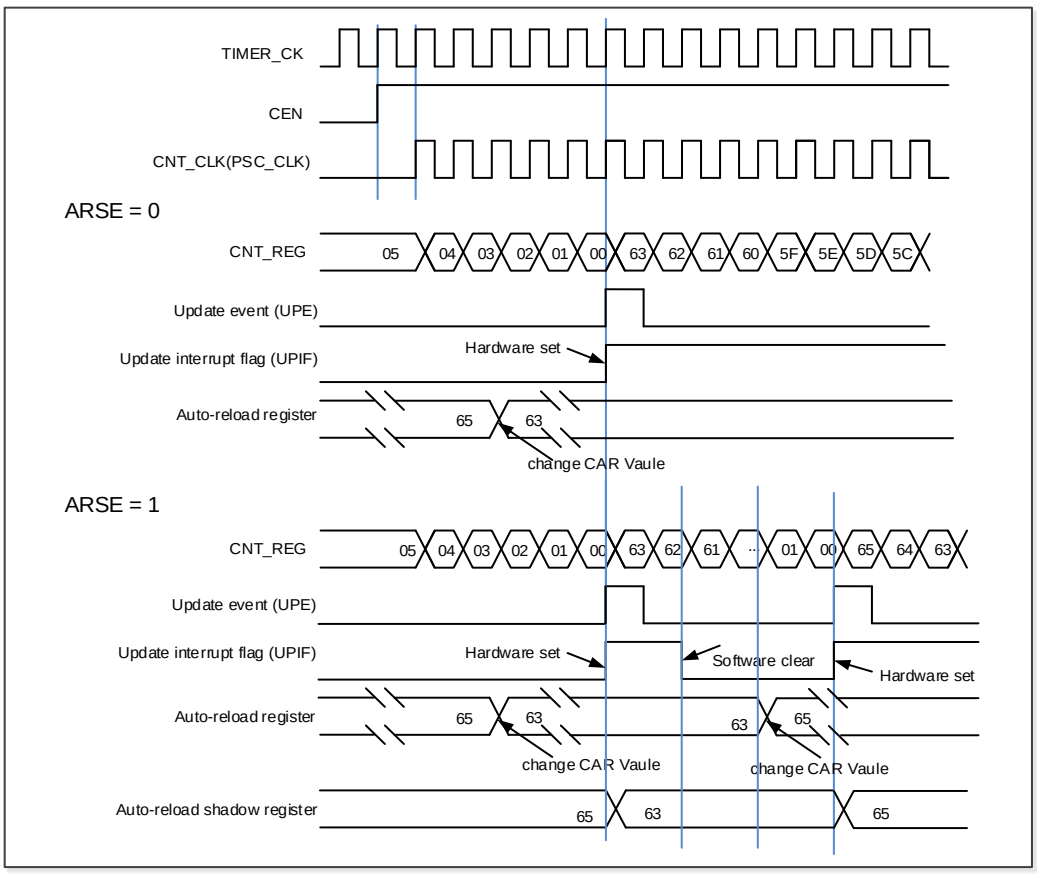


Center-aligned counting mode

In the center-aligned counting mode, the counter counts up from 0 to the counter-reload value and then counts down to 0 alternatively. The Timer module generates an overflow event when the counter counts to the counter-reload value subtract 1 in the up-counting mode and generates an underflow event when the counter counts to 1 in the down-counting mode. The counting direction bit DIR in the TIMERx_CTL0 register is read-only and indicates the counting direction when in the center-aligned mode. The counting direction is updated by hardware automatically.

Setting the UPG bit in the TIMERx_SWEVG register will initialize the counter value to 0 irrespective of whether the counter is counting up or down in the center-align counting mode and generates an update event.

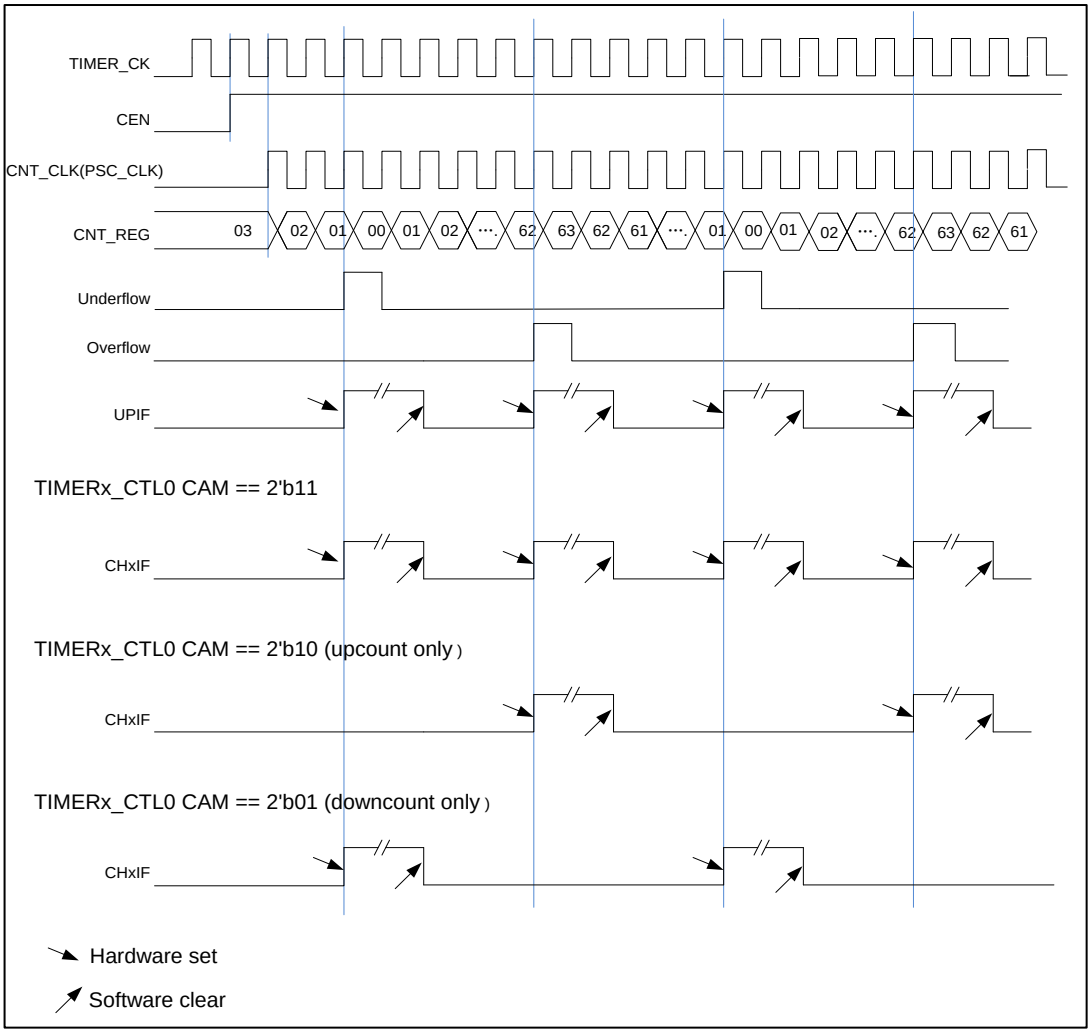
The UPIF bit in the TIMERx_INTF register can be set to 1 either when an underflow event or an overflow event occurs. While the CHxIF bit is associated with the value of CAM in TIMERx_CTL0. The details refer to ***Figure 18-39. Center-aligned counter timechart***.

If the UPDIS bit in the TIMERx_CTL0 register is set, the update event is disabled.

When an update event occurs, all the registers (repetition counter, autoreload register, prescaler register) are updated.

Figure 18-39. Center-aligned counter timechart shows some examples of the counter behavior for different clock frequencies when TIMERx_CAR=0x63, TIMERx_PSC=0x0.

Figure 18-39. Center-aligned counter timechart



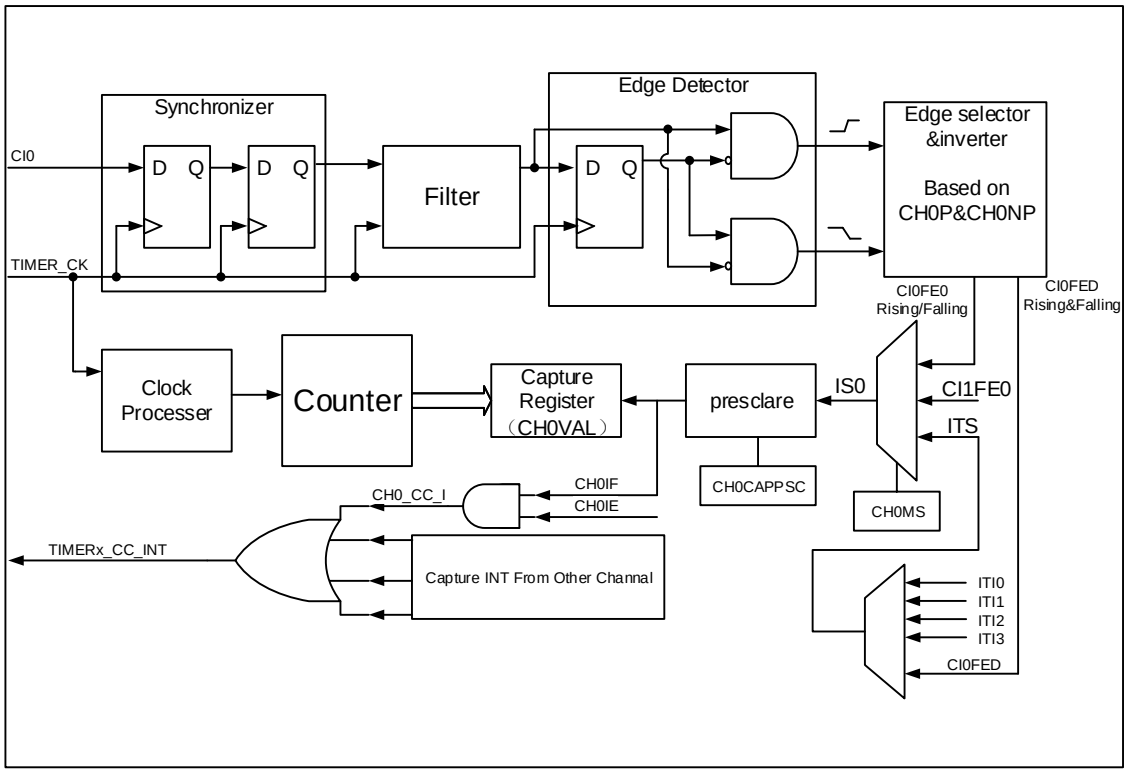
Capture/compare channels

The general level0 Timer has four independent channels which can be used as capture inputs or compare match outputs. Each channel is built around a channel capture compare register, including an input stage, channel controller and an output stage.

■ Input capture mode

Capture mode allows the channel to perform measurements such as pulse timing, frequency, period, duty cycle and so on. The input stage consists of a digital filter, a channel polarity selection, edge detection and a channel prescaler. When a selected edge occurs on the channel input, the current value of the counter is captured into the TIMERx_CHxCV register, at the same time the CHxIF bit is set and the channel interrupt is generated if enabled by CHxIE = 1.

Figure 18-40. Input capture logic



One of channels' input signals (CIx) can be chosen from the TIMERx_CHx signal or the Excusive-OR function of the TIMERx_CH0, TIMERx_CH1 and TIMERx_CH2 signals. First, the channel input signal (CIx) is synchronized to TIMER_CK domain, and then sampled by a digital filter to generate a filtered input signal. Then through the edge detector, the rising and fall edge are detected. You can select one of them by CHxP. One more selector is for the other channel and trig, controlled by CHxMS. Configuring the IC_prescaler enables an effective capture event after a number of input events. On the capture event, CHxVAL will restore the value of Counter.

So the process can be divided to several steps as below:

Step1: Filter Configuration. (CHxCAPFLT in TIMERx_CHCTL0)
Based on the input signal and requested signal quality, configure compatible HxCAPFLT.

Step2: Edge Selection. (CHxP/CHxNP in TIMERx_CHCTL2)
Rising or falling edge, choose one by CHxP/CHxNP.

Step3: Capture source Selection. (CHxMS in TIMERx_CHCTL0)
As soon as you select one input capture source by CHxMS, you have set the channel to input mode (CHxMS != 0x0) and TIMERx_CHxCV cannot be written any more.

Step4: Interrupt enable. (CHxIE and CHxDEN in TIMERx_DMAINTEN)
Enable the related interrupt ; you can got the interrupt and DMA request.

Step5: Capture enable. (CHxEN in TIMERx_CHCTL2)

Result: When you wanted input signal is got, TIMERx_CHxCV will be set by counter's value. And CHxIF is asserted. If the CHxIF is high, the CHxOF will be asserted also. The interrupt and DMA request will be asserted based on the your configuration of CHxIE and CHxDEN in TIMERx_DMAINTEN

Direct generation: If you want to generate a DMA request or interrupt, you can set CHxG by software directly.

The input capture mode can be also used for pulse width measurement from signals on the TIMERx_CHx pins. For example, PWM signal connect to CI0 input. Select channel 0 capture signals to CI0 by setting CH0MS to 2'b01 in the channel control register (TIMERx_CHCTL0) and set capture on rising edge. Select channel 1 capture signal to CI0 by setting CH1MS to 2'b10 in the channel control register (TIMERx_CHCTL0) and set capture on falling edge. The counter set to restart mode and restart on channel 0 rising edge. Then the TIMERX_CH0CV can measure the PWM period and the TIMERx_CH1CV can measure the PWM duty.

- **Output compare mode**

In Output Compare mode, the TIMERx can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CHxVAL register of an output compare channel, the channel (n) output can be set, cleared, or toggled based on CHxCOMCTL. when the counter reaches the value in the CHxVAL register, the CHxIF bit is set and the channel (n) interrupt is generated if CHxIE = 1. And the DMA request will be assert, if CxCDE=1.

So the process can be divided to several steps as below:

Step1: Clock configuration. Such as clock source, clock prescaler and so on.

Step2: Compare mode configuration.

* Set the shadow enable mode by CHxCOMSEN
* Set the output mode (Set/Clear/Toggle) by CHxCOMCTL.
* Select the active high polarity by CHxP/CHxNP
* Enable the output by CHxEN

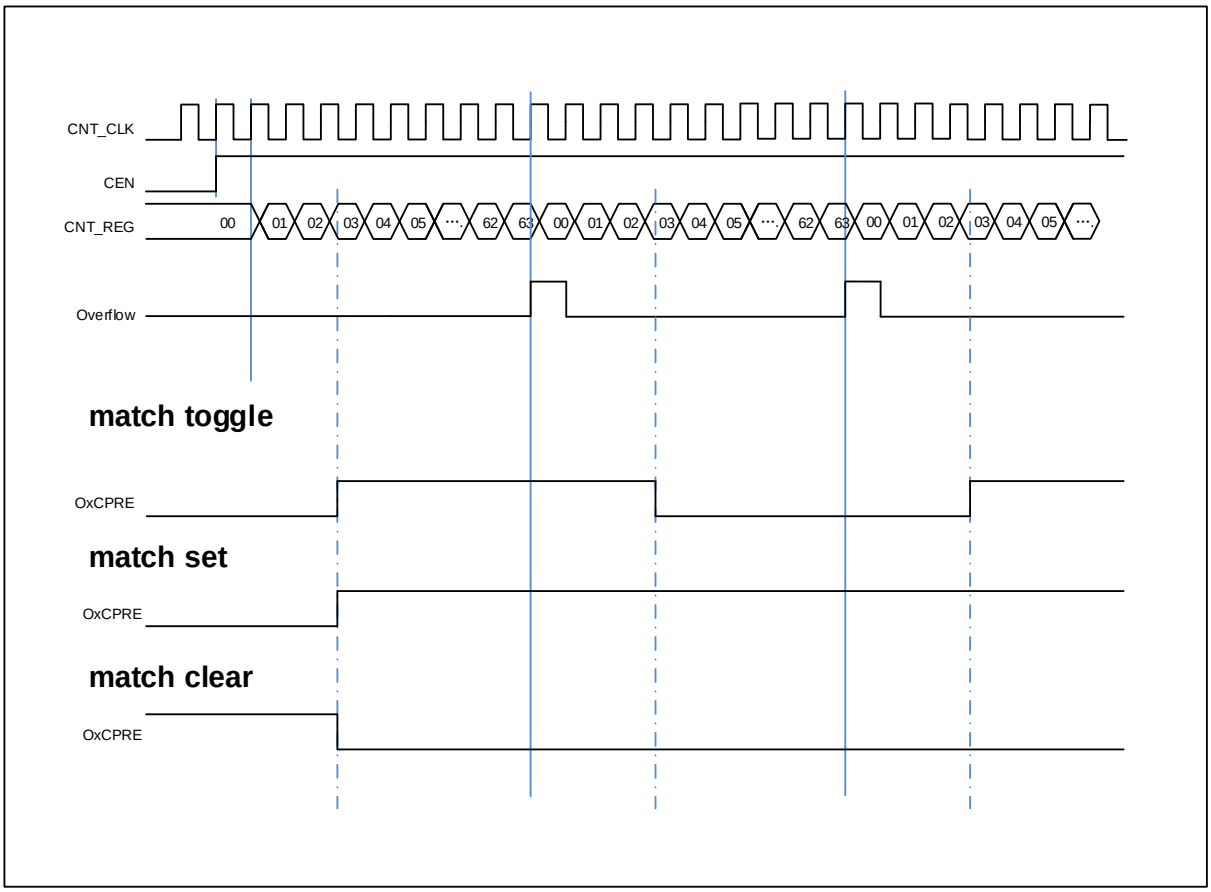
Step3: Interrupt/DMA-request enables configuration by CHxIE/CxCDE

Step4: Compare output timing configuration by TIMERx_CAR and TIMERx_CHxCV. About the CHxVAL, you can change it on the go to meet the waveform you expected.

Step5: Start the counter by CEN.

The timechart below show the three compare modes toggle/set/clear. CAR=0x63, CHxVAL=0x3

Figure 18-41. Output-compare under three modes



PWM mode

In the output PWM mode (by setting the CHxCOMCTL bits to 3'b110 (PWM mode0) or to 3'b 111(PWM mode1), the channel can outputs PWM waveform according to the TIMERx_CAR registers and TIMERx_CHxCV registers.

Based on the counter mode, we have can also divide PWM into EAPWM (Edge aligned PWM) and CAPWM (Centre aligned PWM).

The EAPWM period is determined by TIMERx_CAR and duty cycle is by TIMERx_CHxCV. ***Figure 18-42. EAPWM timechart*** shows the EAPWM output and interrupts waveform.

The CAPWM period is determined by 2*TIMERx_CAR, and duty cycle is determined by 2*TIMERx_CHxCV. ***Figure 18-43. CAPWM timechart*** _Hlk454890020shows the CAPWM output and interrupts waveform.

If TIMERx_CHxCV is greater than TIMERx_CAR, the output will be always active under PWM mode0 (CHxCOMCTL==3'b110).
And if TIMERx_CHxCV is equal to zero, the output will be always inactive under PWM mode0 (CHxCOMCTL==3'b110).

Figure 18-42. EAPWM timechart

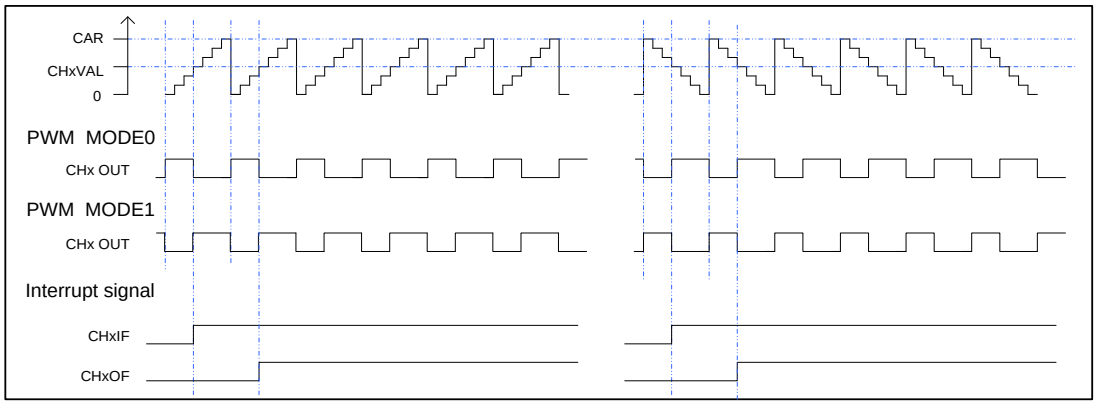


Figure 18-43. CAPWM timechart

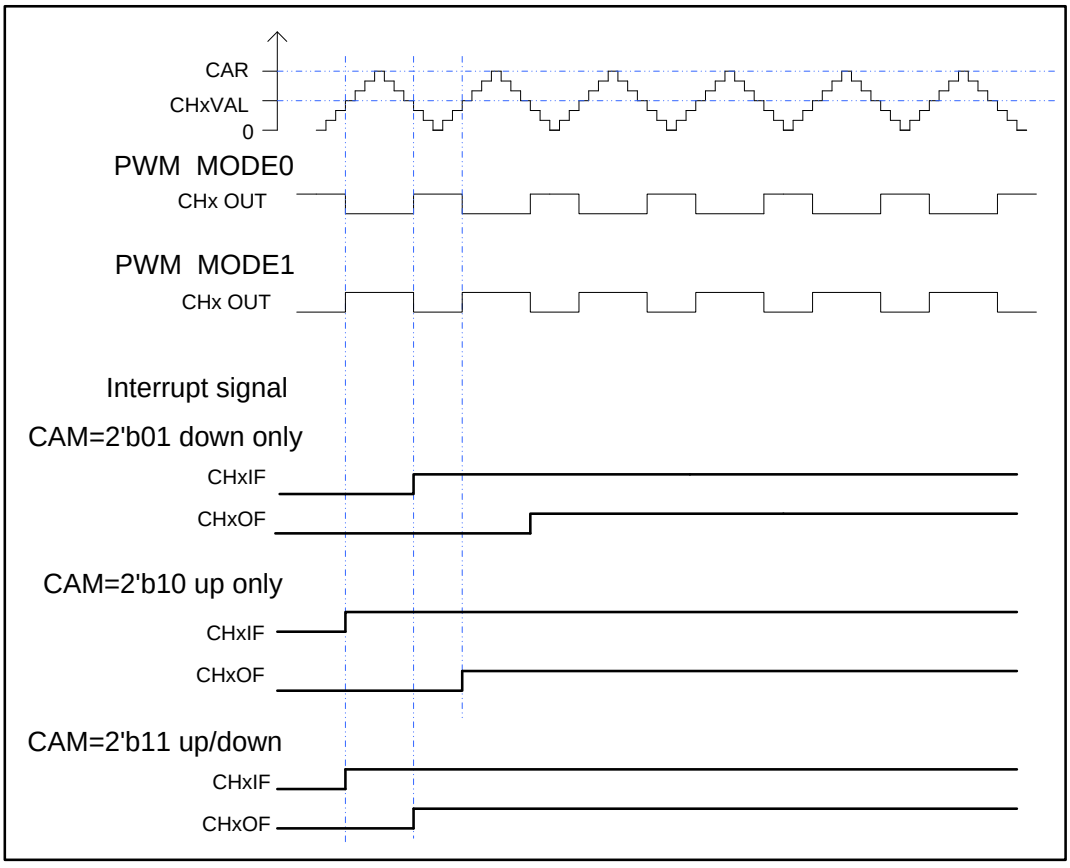

Channel output reference signal

When the TIMERx is used in the compare match output mode, the OxCPRE signal (Channel x Output prepare signal) is defined by setting the CHxCOMCTL filed. The OxCPRE signal has several types of output function. These include, keeping the original level by setting the CHxCOMCTL field to 0x00, set to 1 by setting the CHxCOMCTL field to 0x01, set to 0 by setting the CHxCOMCTL field to 0x02 or signal toggle by setting the CHxCOMCTL field to 0x03 when the counter value matches the content of the TIMERx_CHxCV register.

The PWM mode 0 and PWM mode 1 outputs are also another kind of OxCPRE output which is setup by setting the CHxCOMCTL field to 0x06/0x07. In these modes, the OxCPRE signal level is changed according to the counting direction and the relationship between the counter value and the TIMERx_CHxCV content. With regard to a more detail description refer to the relative bit definition.

Another special function of the OxCPRE signal is a forced output which can be achieved by setting the CHxCOMCTL field to 0x04/0x05. Here the output can be forced to an inactive/active level irrespective of the comparison condition between the counter and the TIMERx_CHxCV values.

The OxCPRE signal can be forced to 0 when the ETIFE signal is derived from the external ETI pin and when it is set to a high level by setting the CHxCOMCEN bit to 1 in the TIMERx_CHCTL0 register. The OxCPRE signal will not return to its active level until the next update event occurs.

Quadrature decoder

The quadrature decoder function uses two quadrature inputs CI0 and CI1 derived from the TIMERx_CH0 and TIMERx_CH1 pins respectively to interact to generate the counter value. The DIR bit is modified by hardware automatically during each input source transition. The input source can be either CI0 only, CI1 only or both CI0 and CI1, the selection made by setting the SMC [2:0] to 0x01, 0x02 or 0x03. The mechanism for changing the counter direction is shown in the following table. The quadrature decoder can be regarded as an external clock with a directional selection. This means that the counter counts continuously in the interval between 0 and the counter-reload value. Therefore, users must configure the TIMERx_CAR register before the counter starts to count.

Table 18-5. Counting direction versus encoder signals

Counting mode	Level	CI0FE0		CI1FE1	
		Rising	Falling	Rising	Falling
CI0 only counting	CI1FE1=High	Down	Up	-	-
	CI1FE1=Low	Up	Down	-	-
CI1 only counting	CI0FE0=High	-	-	Up	Down
	CI0FE0=Low	-	-	Down	Up
CI0 and CI1 counting	CI1FE1=High	Down	Up	X	X
	CI1FE1=Low	Up	Down	X	X
	CI0FE0=High	X	X	Up	Down
	CI0FE0=Low	X	X	Down	Up

Note:"-" means "no counting"; "X" means impossible.

Figure 18-44. Example of counter operation in encoder interface mode

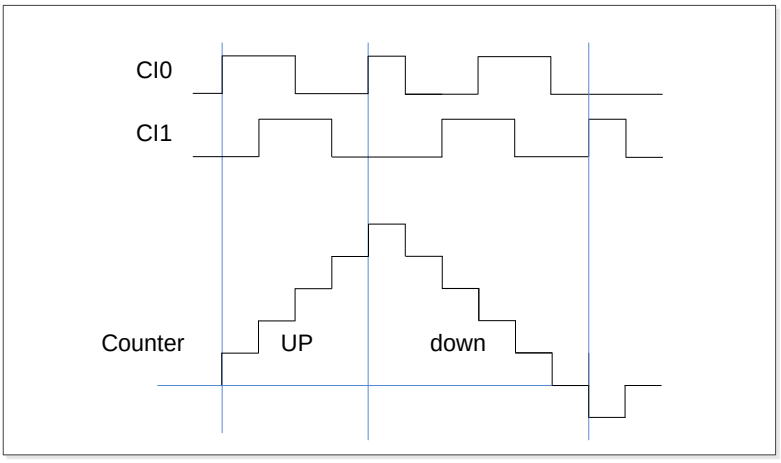

Figure 18-45. Example of encoder interface mode with CI0FE0 polarity inverted

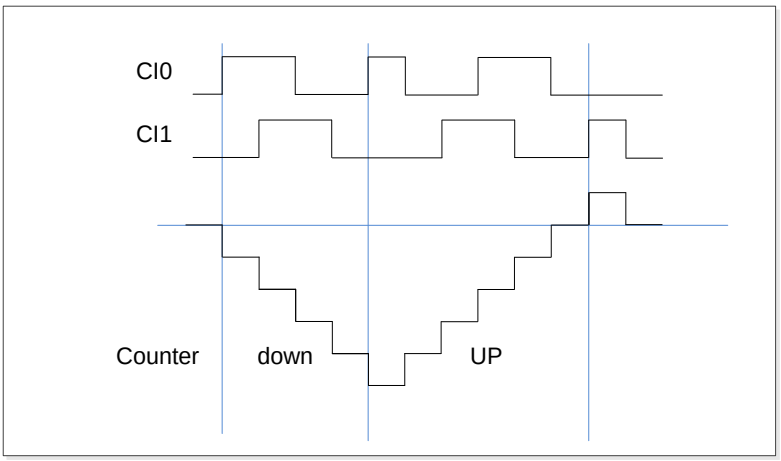


Slave controller

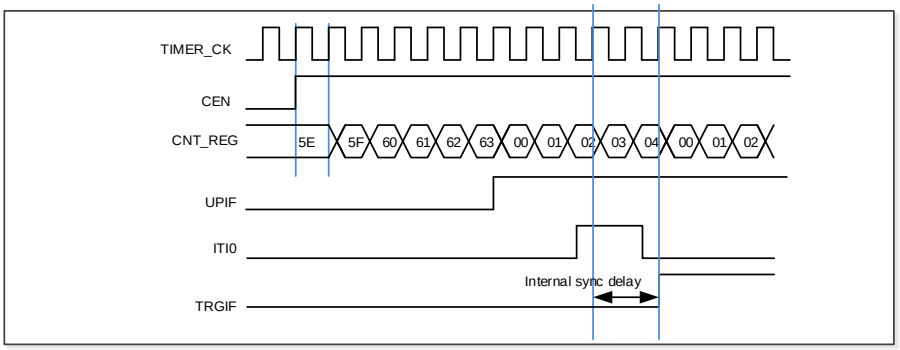
The TIMERx can be synchronized with a trigger in several modes including the restart mode, the pause mode and the event mode which is selected by the SMC [2:0] in the TIMERx_SMCFG register. The trigger input of these modes can be selected by the TRGS [2:0] in the TIMERx_SMCFG register.

Table 18-6. Slave controller examples

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
LIST	SMC[2:0] 3'b100 (restart mode) 3'b101 (pause mode) 3'b110 (event mode)	TRGS[2:0] 000: ITI0 001: ITI1 010: ITI2 011: ITI3 100: CI0F_ED	If you choose the CI0FE0 or CI1FE1, configure the CHxP and CHxNP for the polarity selection and inversion.	For the ITIx no filter and prescaler can be used. For the CIx, configure Filter by CHxCAPFLT, no prescaler can be

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
		101: CI0FE0 110: CI1FE1 111: ETIFP	If you choose the ETIF, configure the ETP for polarity selection and inversion.	used. For the ETIF, configure Filter by ETFC and Prescaler by ETPSC.
Exam1	Restart mode The counter can be clear and restart when a rising trigger input.	TRGS[2:0]=3'b000 ITI0 is the selection.	- For ITI0, no polarity selector can be used.	- For the ITI0, no filter and prescaler can be used.

Figure 18-46. Restart mode

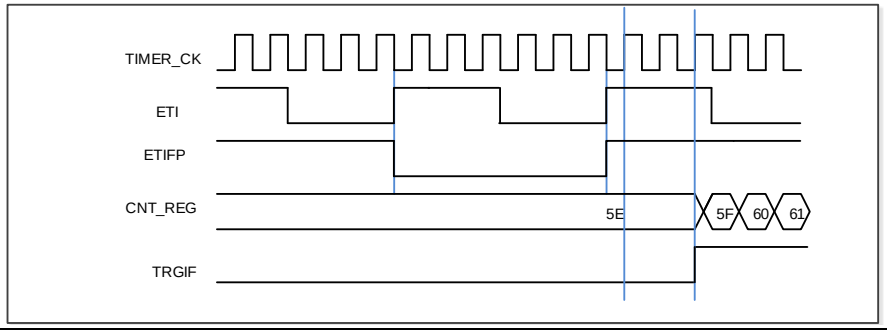


Exam2	Pause mode The counter can be paused when the trigger input is low.	TRGS[2:0]=3'b101 CI0FE0 is the selection.	TI0S=0.（Non-xor）[CH0NP==0, CH0P==0] no inverted. Capture will be sensitive to the rising edge only.	Filter is bypass in this example.

Figure 18-47. Pause mode

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
Exam3	Event mode The counter will start to count when a rising trigger input.	TRGS[2:0]=3'b 111 ETIF is the selection.	ETP = 0 no polarity change.	ETPSC = 1, divided by 2. ETFC = 0 , no filter

Figure 18-48. Event mode



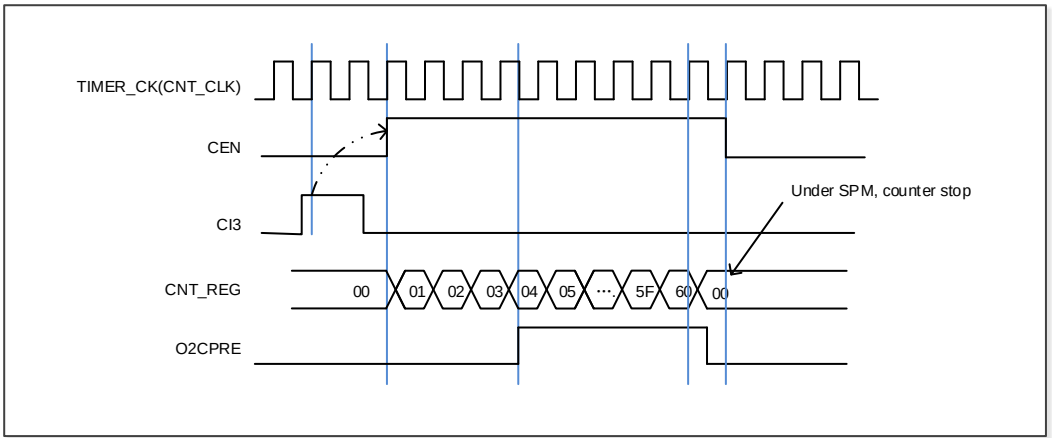
Single pulse mode

Single pulse mode is opposite to the repetitive mode, which can be enabled by setting SPM in TIMERx_CTL0. When you set SPM, the counter will be clear and stop when the next update event automatically. In order to get pulse waveform, you can set the TIMERx to PWM mode or compare by CHxCOMCTL.

Once the timer is set to operate in the single pulse mode, it is not necessary to set the timer enable bit CEN in the TIMERx_CTL0 register to 1 to enable the counter. The trigger to generate a pulse can be sourced from the trigger signals edge or by setting the CEN bit to 1 using software. Setting the CEN bit to 1 or a trigger from the trigger signals edge can generate a pulse and then keep the CEN bit at a high state until the update event occurs or the CEN bit is written to 0 by software. If the CEN bit is cleared to 0 using software, the counter will be stopped and its value held. If the CEN bit is automatically cleared to 0 by a hardware update event, the counter will be reinitialized.

In the single pulse mode, the trigger active edge which sets the CEN bit to 1 will enable the counter. However, there exist several clock delays to perform the comparison result between the counter value and the TIMERx_CHxCV value. In order to reduce the delay to a minimum value, the user can set the CHxCOMFEN bit in each TIMERx_CHCTL0/1 register. After a trigger rising occurs in the single pulse mode, the OxCPRE signal will immediately be forced to the state which the OxCPRE signal will change to, as the compare match event occurs without taking the comparison result into account. The CHxCOMFEN bit is available only when the output channel is configured to operate in the PWM0 or PWM1 output mode and the trigger source is derived from the trigger signal.

Figure 18-49. Single pulse mode TIMERx_CHxCV = 0x04 TIMERx_CAR=0x60



Timers interconnection

Refer to ***Advanced timer (TIMERx, x=0, 7)***.

Timer DMA mode

Timer's DMA mode is the function that configures timer's register by DMA module. The relative registers are TIMERx_DMACFG and TIMERx_DMATB; Of course, you have to enable a DMA request which will be asserted by some internal interrupt event. When the interrupt event was asserted, TIMERx will send a request to DMA, which is configured to M2P mode and PADDR is the TIMERx_DMATB register address, then DMA will access the TIMERx_DMATB. In fact, register TIMERx_DMATB is only a buffer; timer will map the TIMERx_DMATB to an internal register, appointed by the field of DMATA in TIMERx_DMACFG. If the field of DMATC in TIMERx_DMACFG is 0(1 transfer), then the timer's DMA request is finished. While if TIMERx_DMATC is not 0, such as 3(4 transfers), then timer will send 3 more requests to DMA, and DMA will access timer's registers DMASAR+0x4, DMASAR+0x8, DMASAR+0xc at the next 3 accesses to TIMERx_DMATB. In one word, one time DMA internal interrupt event assert, DMATC+1 times request will be send by TIMERx.

If one more time DMA request event coming, TIMERx will repeat the process as above.

Timer debug mode

When the Cortex™-M3 halted, and the TIMERx_HOLD configuration bit in DBG_CTL2 register set to 1, the TIMERx counter stops.

18.2.5. Register definition

TIMER1 start address: 0x4000 0000

TIMER2 start address: 0x4000 0400

TIMER3 start address: 0x4000 0800

TIMER4 start address: 0x4000 0C00

Control register 0 (TIMERx_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CKDIV[1:0]		ARSE	CAM[1:0]		DIR	SPM	UPS	UPDIS	CEN
						rw		rw	rw		rw	rw	rw	rw	rw

Bits	Fields	Descriptions
15:10	Reserved	Must be kept at reset value
9:8	CKDIV[1:0]	Clock division The CKDIV bits can be configured by software to specify division ratio between the timer clock (TIMER_CK) and the dead-time and sampling clock (DTS), which is used by the dead-time generators and the digital filters. 00: $f_{DTS}=f_{TIMER\_CK}$ 01: $f_{DTS}= f_{TIMER\_CK}$ /2 10: $f_{DTS}= f_{TIMER\_CK}$ /4 11: Reserved
7	ARSE	Auto-reload shadow enable 0: The shadow register for TIMERx_CAR register is disabled 1: The shadow register for TIMERx_CAR register is enabled
6:5	CAM[1:0]	Counter aligns mode selection 00: No center-aligned mode (edge-aligned mode). The direction of the counter is specified by the DIR bit. 01: Center-aligned and counting down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting down, compare interrupt flag of channels can be set. 10: Center-aligned and counting up assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting up, compare

interrupt flag of channels can be set.
11: Center-aligned and counting up/down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Both when the counter is counting up and counting down, compare interrupt flag of channels can be set.
After the counter is enabled, CAM[1:0] cannot be switched from 0x00 to non 0x00.

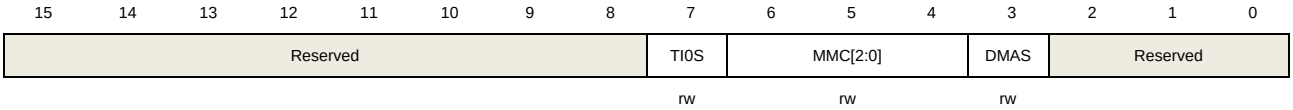
4	DIR	Direction 0: Count up 1: Count down This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.
3	SPM	Single pulse mode. 0: Counter continues after update event. 1: The CEN is cleared by hardware and the counter stops at next update event.
2	UPS	Update source This bit is used to select the update event sources by software. 0: When enabled, any of the following events generate an update interrupt or DMA request: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: When enabled, only counter overflow/underflow generates an update interrupt or DMA request.
1	UPDIS	Update disable. This bit is used to enable or disable the update event generation. 0: update event enable. The update event is generate and the buffered registers are loaded with their preloaded values when one of the following events occurs: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: update event disable. The buffered registers keep their value, while the counter and the prescaler are reinitialized if the UG bit is set or if the slave mode controller generates a hardware reset event.
0	CEN	Counter enable 0: Counter disable 1: Counter enable The CEN bit must be set by software when timer works in external clock, pause mode and encoder mode. While in event mode, the hardware can set the CEN bit automatically.

Control register 1 (TIMERx_CTL1)

Address offset: 0x04

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:8	Reserved	Must be kept at reset value
7	TI0S	Channel 0 trigger input selection 0: The TIMERx_CH0 pin input is selected as channel 0 trigger input. 1: The result of combinational XOR of TIMERx_CH0, CH1 and CH2 pins is selected as channel 0 trigger input.
6:4	MMC[2:0]	Master mode control These bits control the selection of TRGO signal, which is sent in master mode to slave timers for synchronization function. 000: Reset. When the UPG bit in the TIMERx_SWEVG register is set or a reset is generated by the slave mode controller, a TRGO pulse occurs. And in the latter case, the signal on TRGO is delayed compared to the actual reset. 001: Enable. This mode is useful to start several timers at the same time or to control a window in which a slave timer is enabled. In this mode the master mode controller selects the counter enable signal TIMERx_EN as TRGO. The counter enable signal is set when CEN control bit is set or the trigger input in pause mode is high. There is a delay between the trigger input in pause mode and the TRGO output, except if the master-slave mode is selected. 010: Update. In this mode the master mode controller selects the update event as TRGO. 011: Capture/compare pulse. In this mode the master mode controller generates a TRGO pulse when a capture or a compare match occurred. 100: Compare. In this mode the master mode controller selects the O0CPRE signal as TRGO 101: Compare. In this mode the master mode controller selects the O1CPRE signal as TRGO 110: Compare. In this mode the master mode controller selects the O2CPRE signal as TRGO 111: Compare. In this mode the master mode controller selects the O3CPRE signal as TRGO
3	DMAS	DMA request source selection 0: DMA request of channel x is sent when channel x event occurs.

		1: DMA request of channel x is sent when update event occurs.
2:0	Reserved	Must be kept at reset value.

Slave mode configuration register (TIMERx_SMCFG)

Address offset: 0x08
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	SMC1	ETPSC[1:0]		ETFC[3:0]				MSM	TRGS[2:0]			Reserved	SMC[2:0]		
rw	rw	rw		rw				rw	rw				rw		

Bits	Fields	Descriptions
15	ETP	External trigger polarity This bit specifies the polarity of ETI signal 0: ETI is active at high level or rising edge. 1: ETI is active at low level or falling edge.
14	SMC1	Part of SMC for enable External clock mode1. In external clock mode 1, the counter is clocked by any active edge on the ETIF signal. 0: External clock mode 1 disabled 1: External clock mode 1 enabled. It is possible to simultaneously use external clock mode 1 with the restart mode, pause mode or event mode. But the TRGS bits must not be 3'b111 in this case. The external clock input will be ETIF if external clock mode 0 and external clock mode 1 are enabled at the same time. **Note:** External clock mode 0 enable is in this register's SMC bit-filed.
13:12	ETPSC[1:0]	External trigger prescaler The frequency of external trigger signal ETI must not be at higher than 1/4 of TIMER_CK frequency. When the external trigger signal is a fast clock, the prescaler can be enabled to reduce ETI frequency. 00: Prescaler disable 01: ETI frequency will be divided by 2 10: ETI frequency will be divided by 4 11: ETI frequency will be divided by 8
11:8	ETFC[3:0]	External trigger filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample ETI signal and the length of the digital filter applied to ETI. 0000: Filter disabled. f_{SAMP}= f_{DTS}, N=1.

0001: f_{SAMP}= f_{TIMER_CK}, N=2.
0010: f_{SAMP}= f_{TIMER_CK}, N=4.
0011: f_{SAMP}= f_{TIMER_CK}, N=8.
0100: f_{SAMP}=f_{DTS}/2, N=6.
0101: f_{SAMP}=f_{DTS}/2, N=8.
0110: f_{SAMP}=f_{DTS}/4, N=6.
0111: f_{SAMP}=f_{DTS}/4, N=8.
1000: f_{SAMP}=f_{DTS}/8, N=6.
1001: f_{SAMP}=f_{DTS}/8, N=8.
1010: f_{SAMP}=f_{DTS}/16, N=5.
1011: f_{SAMP}=f_{DTS}/16, N=6.
1100: f_{SAMP}=f_{DTS}/16, N=8.
1101: f_{SAMP}=f_{DTS}/32, N=5.
1110: f_{SAMP}=f_{DTS}/32, N=6.
1111: f_{SAMP}=f_{DTS}/32, N=8.

7	MSM	Master-slave mode This bit can be used to synchronize selected timers to begin counting at the same time. The TRGI is used as the start event, and through TRGO, timers are connected together. 0: Master-slave mode disable 1: Master-slave mode enable
6:4	TRGS[2:0]	Trigger selection This bit-field specifies which signal is selected as the trigger input, which is used to synchronize the counter. 000: Internal trigger input 0 (ITI0) 001: Internal trigger input 1 (ITI1) 010: Internal trigger input 2 (ITI2) 011: Internal trigger input 3 (ITI3) 100: CI0 edge flag (CI0F_ED) 101: channel 0 input Filtered output (CI0FE0) 110: channel 1 input Filtered output (CI1FE1) 111: External trigger input filter output(ETIFP) These bits must not be changed when slave mode is enabled. **Timer 1 Internal trigger input source 1 is decided by TIMER1ITR0_REMAP**.
3	Reserved	Must be kept at reset value.
2:0	SMC[2:0]	Slave mode control 000: Disable mode. The slave mode is disabled; The prescaler is clocked directly by the internal clock (TIMER_CK) when CEN bit is set high. 001: Quadrature decoder mode 0.The counter counts on CI1FE1 edge, while the direction depends on CI0FE0 level. 010: Quadrature decoder mode 1.The counter counts on CI0FE0 edge, while the

direction depends on CI1FE1 level.
011: Quadrature decoder mode 2.The counter counts on both CI0FE0 and CI1FE1 edge, while the direction depends on each other.
100: Restart mode. The counter is reinitialized and the shadow registers are updated on the rising edge of the selected trigger input.
101: Pause mode. The trigger input enables the counter clock when it is high and disables the counter when it is low.
110: Event mode. A rising edge of the trigger input enables the counter. The counter cannot be disabled by the slave mode controller.
111: External clock mode0. The counter counts on the rising edges of the selected trigger.

DMA and interrupt enable register (TIMERx_DMAINTEN)

Address offset: 0x0C
Reset value: 0x0000

9:8	CH1MS[1:0]	Channel 1 mode selection This bit-field specifies the direction of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH1EN bit in TIMERx_CHCTL2 register is reset). 00: Channel 1 is configured as output 01: Channel 1 is configured as input, IS1 is connected to CI0FE1 10: Channel 1 is configured as input, IS1 is connected to CI1FE1 11: Channel 1 is configured as input, IS1 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.
7	CH0COMCEN	Channel 0 output compare clear enable. When this bit is set, the O0CPRE signal is cleared when High level is detected on ETIF input. 0: Channel 0 output compare clear disable 1: Channel 0 output compare clear enable
6:4	CH0COMCTL[2:0]	Channel 0 compare output control This bit-field controls the behavior of the output reference signal O0CPRE which drives CH0_O and CH0_ON. O0CPRE is active high, while CH0_O and CH0_ON active level depends on CH0P and CH0NP bits. 000: Frozen. The O0CPRE signal keeps stable, independent of the comparison

between the register TIMERx_CH0CV and the counter TIMERx_CNT.
001: Set the channel output. O0CPRE signal is forced high when the counter matches the output compare register TIMERx_CH0CV.
010: Clear the channel output. O0CPRE signal is forced low when the counter matches the output compare register TIMERx_CH0CV.
011: Toggle on match. O0CPRE toggles when the counter matches the output compare register TIMERx_CH0CV.
100: Force low. O0CPRE is forced low level.
101: Force high. O0CPRE is forced high level.
110: PWM mode0. When counting up, O0CPRE is high as long as the counter is smaller than TIMERx_CH0CV,otherwise it is low. When counting down, O0CPRE is low as long as the counter is larger than TIMERx_CH0CV,otherwise it is high.
111: PWM mode1. When counting up, O0CPRE is low as long as the counter is smaller than TIMERx_CH0CV, otherwise it is high. When counting down, O0CPRE is high as long as the counter is larger than TIMERx_CH0CV, otherwise it is low.
When configured in PWM mode, the O0CPRE level changes only when the output compare mode switches from “frozen” mode to “PWM” mode or when the result of the comparison changes.
This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00(COMPARE MODE).

3	CH0COMSEN	Channel 0 compare output shadow enable When this bit is set, the shadow register of TIMERx_CH0CV register, which updates at each update event, will be enabled. 0: Channel 0 output compare shadow disable 1: Channel 0 output compare shadow enable The PWM mode can be used without validating the shadow register only in single pulse mode (SPM bit in TIMERx_CTL0 register is set). This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00.
2	CH0COMFEN	Channel 0 output compare fast enable When this bit is set, the effect of an event on the trigger in input on the capture/compare output will be accelerated if the channel is configured in PWM0 or PWM1 mode. The output channel will treat an active edge on the trigger input as a compare match, and CH0_O is set to the compare level independently from the result of the comparison. 0: Channel 0 output quickly compare disable. The minimum delay from an edge on the trigger input to activate CH0_O output is 5 clock cycles. 1: Channel 0 output quickly compare enable. The minimum delay from an edge on the trigger input to activate CH0_O output is 3 clock cycles.
1:0	CH0MS[1:0]	Channel 0 I/O mode selection This bit-field specifies the work mode of the channel and the input signal selection.

This bit-field is writable only when the channel is not active. (CH0EN bit in TIMERx_CHCTL2 register is reset).).
00: Channel 0 is configured as output
01: Channel 0 is configured as input, IS0 is connected to CI0FE0
10: Channel 0 is configured as input, IS0 is connected to CI1FE0
11: Channel 0 is configured as input, IS0 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.

Input capture mode:

Bits	Fields	Descriptions
15:12	CH1CAPFLT[3:0]	Channel 1 input capture filter control Refer to CH0CAPFLT description
11:10	CH1CAPPSC[1:0]	Channel 1 input capture prescaler Refer to CH0CAPPSC description
9:8	CH1MS[1:0]	Channel 1 mode selection Same as Output compare mode
7:4	CH0CAPFLT[3:0]	Channel 0 input capture filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample CI0 input signal and the length of the digital filter applied to CI0. 0000: Filter disabled, $f_{SAMP}=f_{DTS}$, N=1 0001: $f_{SAMP}=f_{TIMER\_CK}$, N=2 0010: $f_{SAMP}= f_{TIMER\_CK}$, N=4 0011: $f_{SAMP}= f_{TIMER\_CK}$, N=8 0100: $f_{SAMP}=f_{DTS}/2$, N=6 0101: $f_{SAMP}=f_{DTS}/2$, N=8 0110: $f_{SAMP}=f_{DTS}/4$, N=6 0111: $f_{SAMP}=f_{DTS}/4$, N=8 1000: $f_{SAMP}=f_{DTS}/8$, N=6 1001: $f_{SAMP}=f_{DTS}/8$, N=8 1010: $f_{SAMP}=f_{DTS}/16$, N=5 1011: $f_{SAMP}=f_{DTS}/16$, N=6 1100: $f_{SAMP}=f_{DTS}/16$, N=8 1101: $f_{SAMP}=f_{DTS}/32$, N=5 1110: $f_{SAMP}=f_{DTS}/32$, N=6 1111: $f_{SAMP}=f_{DTS}/32$, N=8
3:2	CH0CAPPSC[1:0]	Channel 0 input capture prescaler This bit-field specifies the factor of the prescaler on channel 0 input. The prescaler is reset when CH0EN bit in TIMERx_CHCTL2 register is clear. 00: Prescaler disable, capture is done on each channel input edge

		01: Capture is done every 2 channel input edges 10: Capture is done every 4 channel input edges 11: Capture is done every 8 channel input edges
1:0	CH0MS[1:0]	Channel 0 mode selection Same as Output compare mode

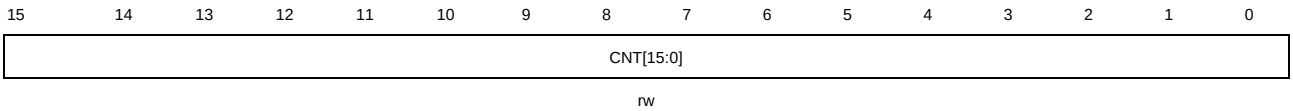
4	CH1EN	Channel 1 capture/compare function enable Refer to CH0EN description
3:2	Reserved	Must be kept at reset value
1	CH0P	Channel 0 capture/compare function polarity When channel 0 is configured in output mode, this bit specifies the output signal polarity. 0: Channel 0 active high 1: Channel 0 active low When channel 0 is configured in input mode, this bit specifies the CI0 signal polarity. 0: Channel 0 non-inverted 1: Channel 0 inverted
0	CH0EN	Channel 0 capture/compare function enable When channel 0 is configured in output mode, setting this bit enables CH0_O signal in active state. When channel 0 is configured in input mode, setting this bit enables the capture event in channel0. 0: Channel 0 disabled 1: Channel 0 enabled

Counter register (TIMERx_CNT)

Address offset: 0x24
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

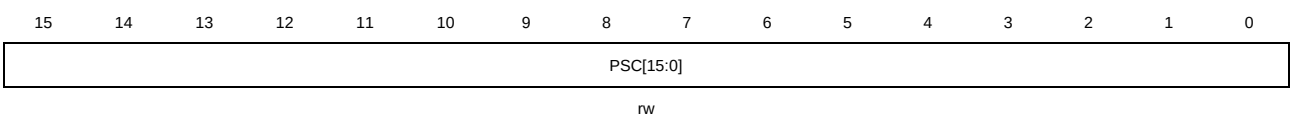


Bits	Fields	Descriptions
15:0	CNT[15:0]	This bit-filed indicates the current counter value. Writing to this bit-filed can change the value of the counter.

Prescaler register (TIMERx_PSC)

Address offset: 0x28
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

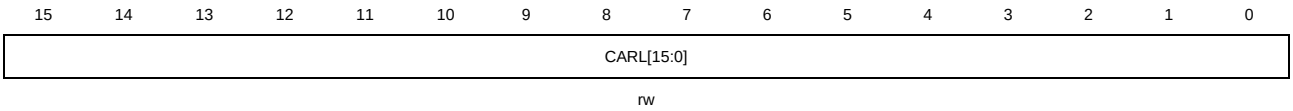


Bits	Fields	Descriptions
15:0	PSC[15:0]	Prescaler value of the counter clock The PSC clock is divided by (PSC+1) to generate the counter clock. The value of this bit-filed will be loaded to the corresponding shadow register at every update event.

Counter auto reload register (TIMERx_CAR)

Address offset: 0x2C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

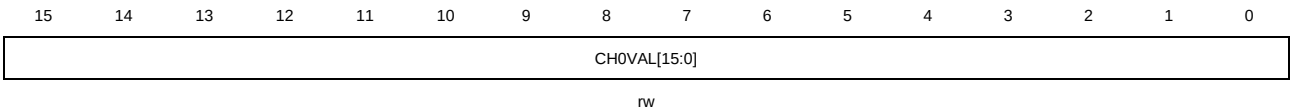


Bits	Fields	Descriptions
15:0	CARL[15:0]	Counter auto reload value This bit-filed specifies the auto reload value of the counter.

Channel 0 capture/compare value register (TIMERx_CH0CV)

Address offset: 0x34
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:0	CH0VAL[15:0]	Capture or compare value of channel0 When channel 0 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 0 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 1 capture/compare value register (TIMERx_CH1CV)

Address offset: 0x38
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH1VAL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CH1VAL[15:0]	Capture or compare value of channel1 When channel 1 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 1 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 2 capture/compare value register (TIMERx_CH2CV)

Address offset: 0x3C

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH2VAL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CH2VAL[15:0]	Capture or compare value of channel 2 When channel 2 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 2 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 3 capture/compare value register (TIMERx_CH3CV)

Address offset: 0x40

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CH3VAL[15:0]															
rw															

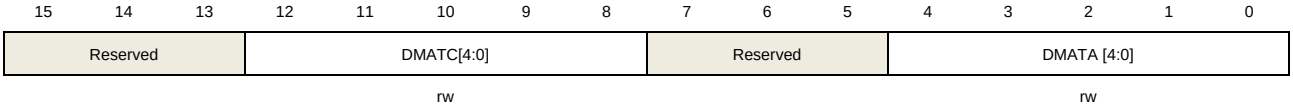
Bits	Fields	Descriptions
15:0	CH3VAL[15:0]	Capture or compare value of channel 3 When channel3 is configured in input mode, this bit-filed indicates the counter

value corresponding to the last capture event. And this bit-filed is read-only. When channel 3 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

DMA configuration register (TIMERx_DMACFG)

Address offset: 0x48
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

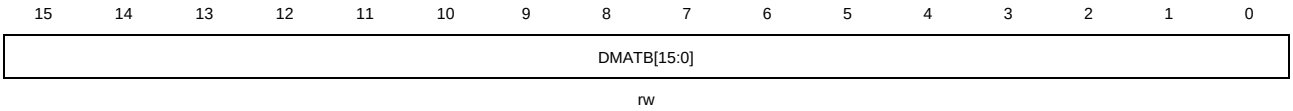


Bits	Fields	Descriptions
15:14	Reserved	Must be kept at reset value.
12:8	DMATC [4:0]	DMA transfer count This filed is defined the number of DMA will access(R/W) the register of TIMERx_DMATB
7:5	Reserved	Must be kept at reset value.
4:0	DMATA [4:0]	DMA transfer access start address This filed define the first address for the DMA access the TIMERx_DMATB. When access is done through the TIMERx_DMA address first time, this bit-field specifies the address you just access. And then the second access to the TIMERx_DMATB, you will access the address of start address + 0x4. 5'b0_0000: TIMERx_CTL0 5'b0_0001: TIMERx_CTL1 … In a word: Start Address = TIMERx_CTL0 + DMASAR*4

DMA transfer buffer register (TIMERx_DMATB)

Address offset: 0x4C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:0	DMATB[15:0]	DMA transfer buffer When a read or write operation is assigned to this register, the register located at the address range (Start Addr + Transfer Timer* 4) will be accessed. The transfer Timer is calculated by hardware, and ranges from 0 to DMATC.

18.3. General level1 timer (TIMERx, x=8, 11)

18.3.1. Overview

The general level1 timer module (Timer8, 11) is a two-channel timer that supports input capture, output compare. They can generate PWM signals to control motor or be used for power management applications. The general level1 time reference is a 16-bit counter that can be used as an unsigned counter.

In addition, the general level1 timers can be programmed and be used to count or time external events that drive other Timers.

Timer and timer are completely independent, but there may be synchronized to provide a larger timer with their counters incrementing in unison.

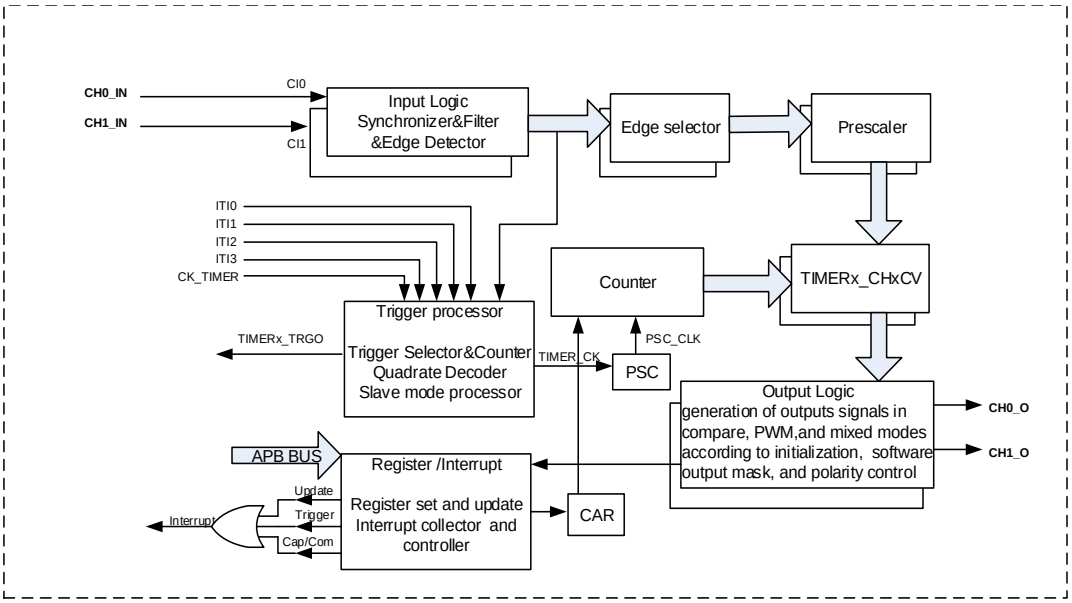
18.3.2. Characteristics

- Total channel num: 2.
- Counter width: 16bit.
- Source of count clock is selectable:
  internal clock, internal trigger, external input, external trigger.
- Multiple counter modes: count up, count down, count up/down.
- Programmable prescaler: 16 bit. Factor can be changed on the go.
- Each channel is user-configurable:
  Input capture mode, Output compare mode, Programmable PWM mode, Single pulse mode
- Auto-reload function.
- Interrupt output on: update, trigger event, and compare/capture event.
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events.
- Timer synchronization allows selected timers to start counting on the same clock cycle.
- Timer Master/Slave mode controller.

18.3.3. Block diagram

Figure 18-50. General level1 timer block diagram provides details on the internal configuration of the general level1 timer.

Figure 18-50. General level1 timer block diagram



18.3.4. Function overview

Clock selection

The general level1 TIMER has the capability of being clocked by either the CK_TIMER or an alternate clock source controlled by SMC (TIMERx_SMCFG bit [2:0]).

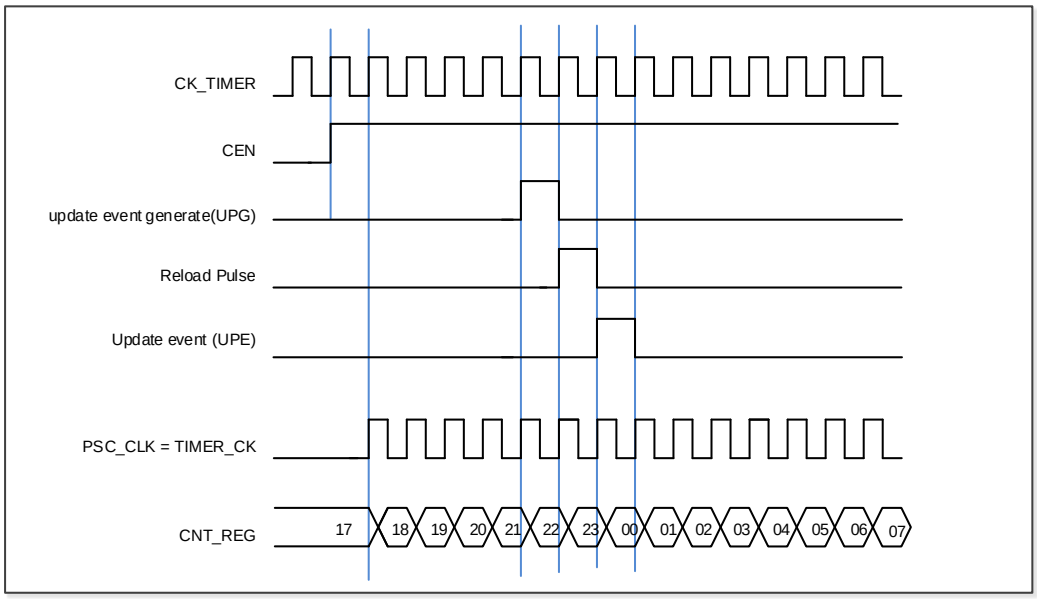
- SMC [2:0] == 3'b000. Internal timer clock CK_TIMER which is from module RCU.

The default internal clock source is the CK_TIMER used to drive the counter prescaler when the slave mode is disabled (SMC [2:0] == 3'b000). When the CEN is set, the CK_TIMER will be divided by PSC value to generate PSC_CLK.

In this mode, the TIMER_CK, driven counter's prescaler to count, is equal to CK_TIMER which is from RCU.

If the slave mode controller is enabled by setting SMC [2:0] in the TIMERx_SMCFG register to an available value including 0x1, 0x2, 0x3 and 0x7, the prescaler is clocked by other clock sources selected by the TRGS [2:0] in the TIMERx_SMCFG register and described as follows. When the slave mode selection bits SMC are set to 0x4, 0x5 or 0x6, the internal clock TIMER_CK is the counter prescaler driving clock source.

Figure 18-51. Normal mode, internal clock divided by 1



- SMC [2:0] == 3'b111 (external clock mode 0). External input pin source

The TIMER_CK, driven counter's prescaler to count, can be triggered by the event of rising or falling edge on the external pin TIMERx_CI0/TIMERx_CI1. This mode can be selected by setting SMC [2:0] to 0x7 and the TRGS [2:0] to 0x4, 0x5 or 0x6.

And, the counter prescaler can also be driven by rising edge on the internal trigger input pin ITI0/1/2/3. This mode can be selected by setting SMC [2:0] to 0x7 and the TRGS [2:0] to 0x0, 0x1, 0x2 or 0x3.

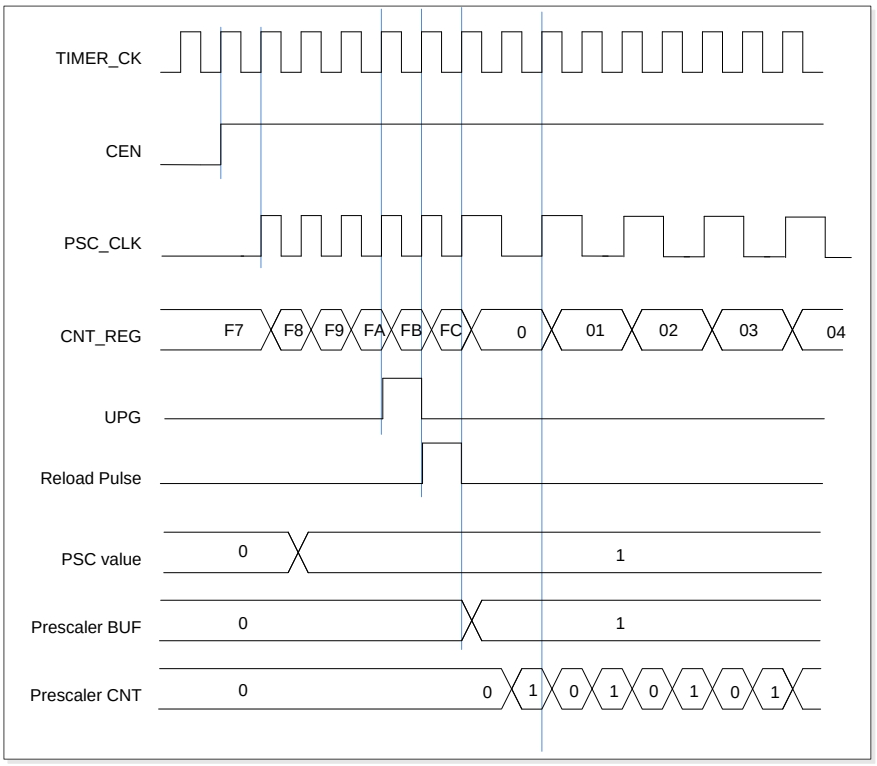
- SMC1== 1'b1 (external clock mode 1). External input pin source (ETI)

The TIMER_CK, driven counter's prescaler to count, can be triggered by the event of rising or falling edge on the external pin ETI. This mode can be selected by setting the SMC1 bit in the TIMERx_SMCFG register to 1. The other way to select the ETI signal as the clock source is set the SMC [2:0] to 0x7 and the TRGS [2:0] to 0x7 respectively. Note that the ETI signal is derived from the ETI pin sampled by a digital filter. When the clock source is selected to come from the ETI signal, the Trigger Controller including the edge detection circuitry will generate a clock pulse during each ETI signal rising edge to clock the counter prescaler.

Prescaler

The prescaler can divide the timer clock (TIMER_CK) to the counter clock (PSC_CLK by any factor between 1 and 65536. It is controlled through prescaler register (TIMERx_PSC) which can be changed on the go but be taken into account at the next update event.

Figure 18-52. Counter timing diagram with prescaler division change from 1 to 2



Up counting mode

In this mode, the counter counts up continuously from 0 to the counter-reload value, which is defined in the TIMERx_CAR register, in a count-up direction. Once the counter reaches the counter reload value, the counter restarts to count once again from 0. The update event is generated at each counter overflow. The counting direction bit DIR in the TIMERx_CTL1 register should be set to 0 for the up counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to 0 and generates an update event.

If the UPDIS bit in TIMERx_CTL0 register is set, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior for different clock prescaler factor when TIMERx_CAR=0x63.

Figure 18-53. Up-counter timechart, PSC=0/1

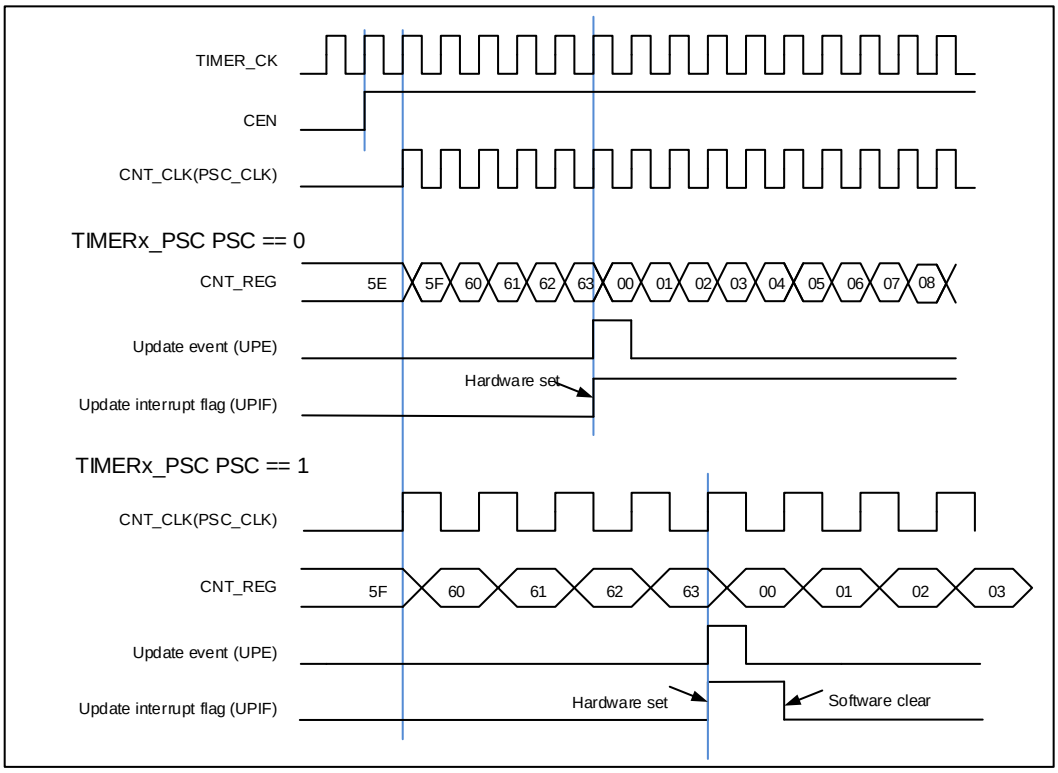


Figure 18-54. Up-counter timechart, change TIMERx_CAR on the go.

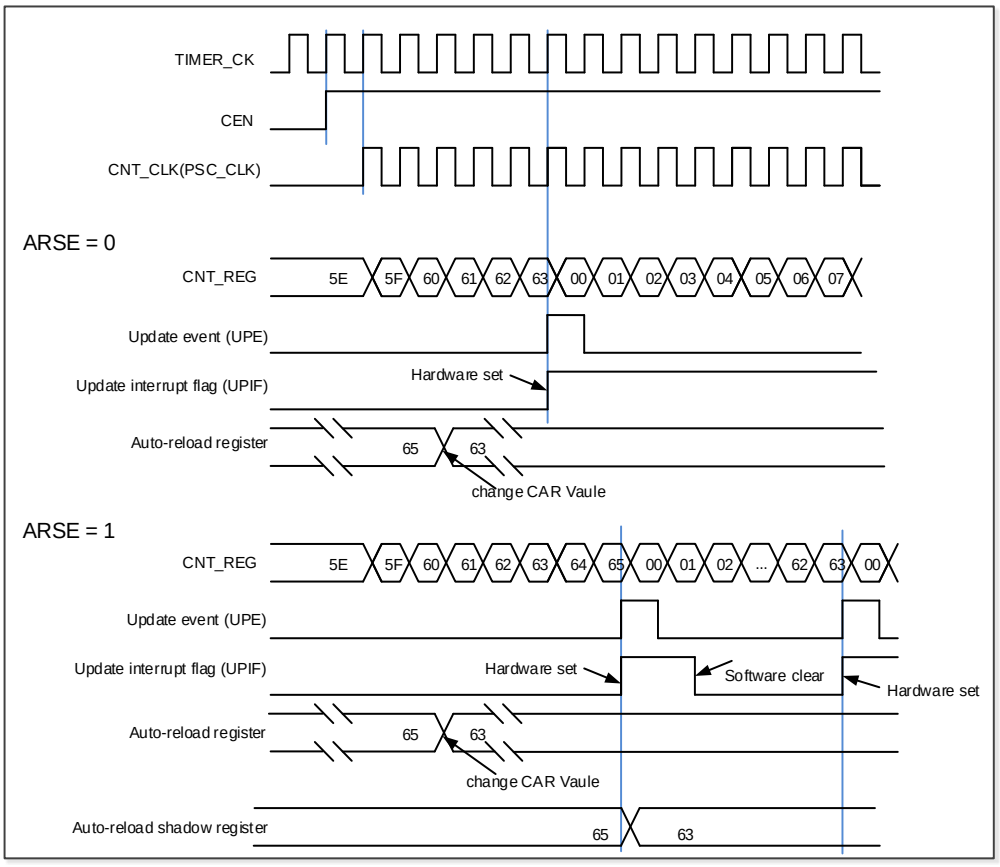

Down counting mode

In this mode, the counter counts down continuously from the counter-reload value, which is defined in the TIMERx_CAR register, to 0 in a count-down direction. Once the counter reaches to 0, the counter restarts to count again from the counter-reload value. If the repetition counter is set, the update event will be generated after (TIMERx_CREP+1) times of underflow. Otherwise the update event is generated each time when underflows. The counting direction bit DIR in the TIMERx_CTL0 register should be set to 1 for the down-counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to the counter-reload value and generates an update event.

If set the UPDIS bit in TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior in different clock frequencies when TIMERx_CAR=0x63.

Figure 18-55. Down-counter timechart, PSC=0/1

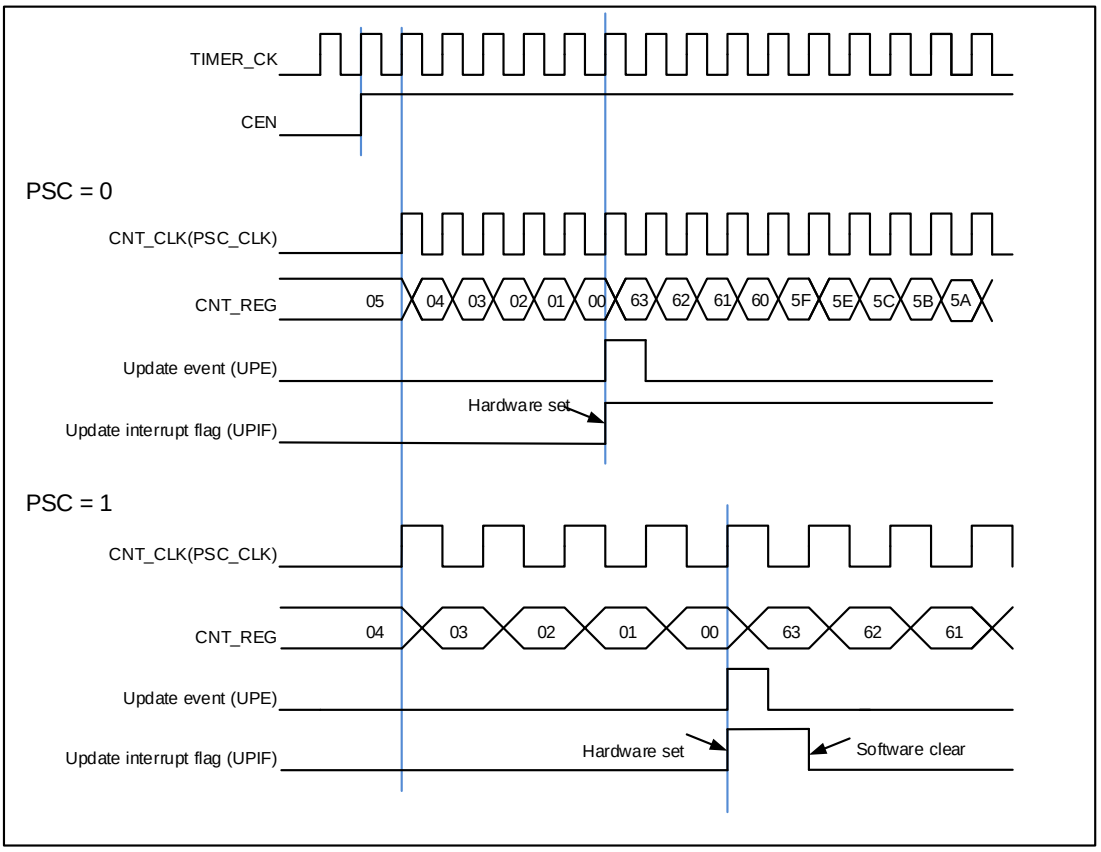

Figure 18-56. Down-counter timechart, change TIMERx_CAR on the go

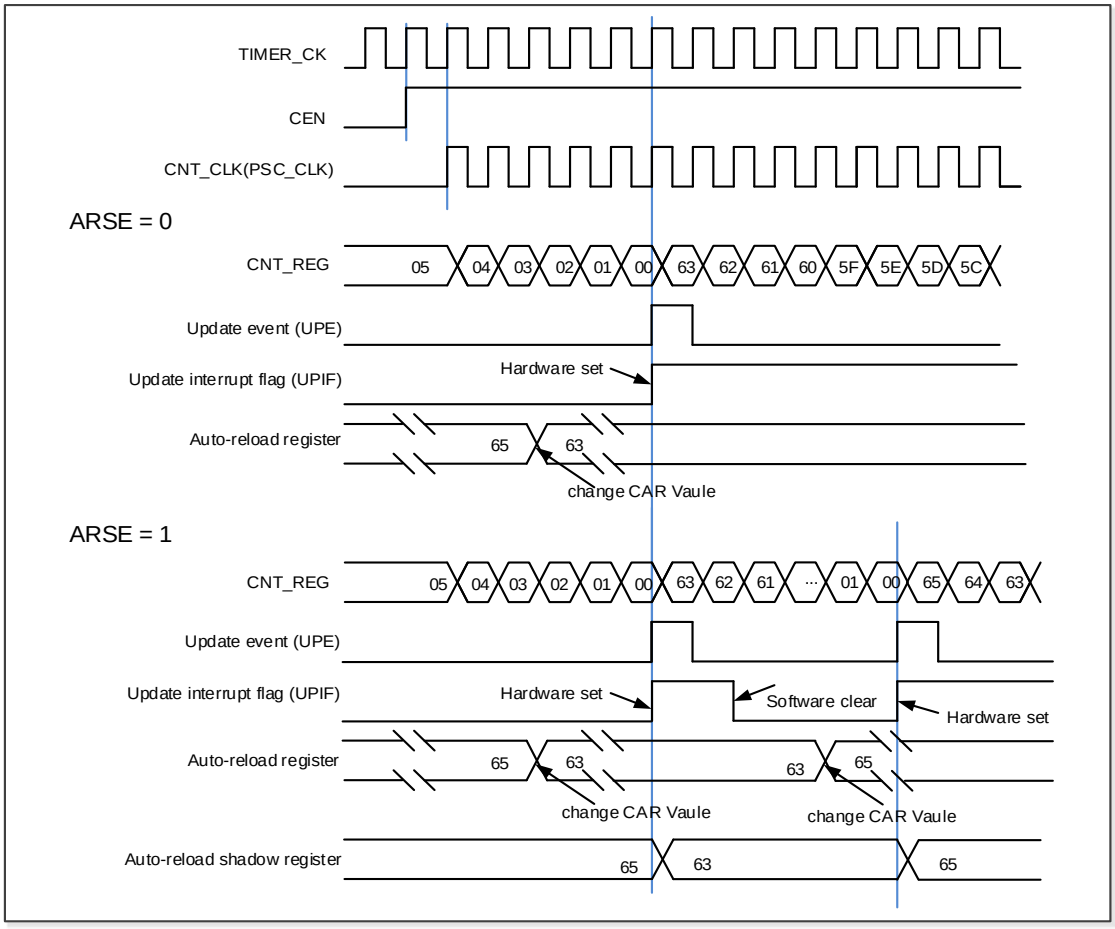


Center-aligned counting mode

In the center-aligned counting mode, the counter counts up from 0 to the counter-reload value and then counts down to 0 alternatively. The Timer module generates an overflow event when the counter counts to the counter-reload value subtract 1 in the up-counting direction and generates an underflow event when the counter counts to 1 in the down-counting direction. The counting direction bit DIR in the TIMERx_CTL0 register is read-only and indicates the counting direction when in the center-aligned mode. The counting direction is updated by hardware automatically.

Setting the UPG bit in the TIMERx_SWEVG register will initialize the counter value to 0 and generates an update event irrespective of whether the counter is counting up or down in the center-align counting mode.

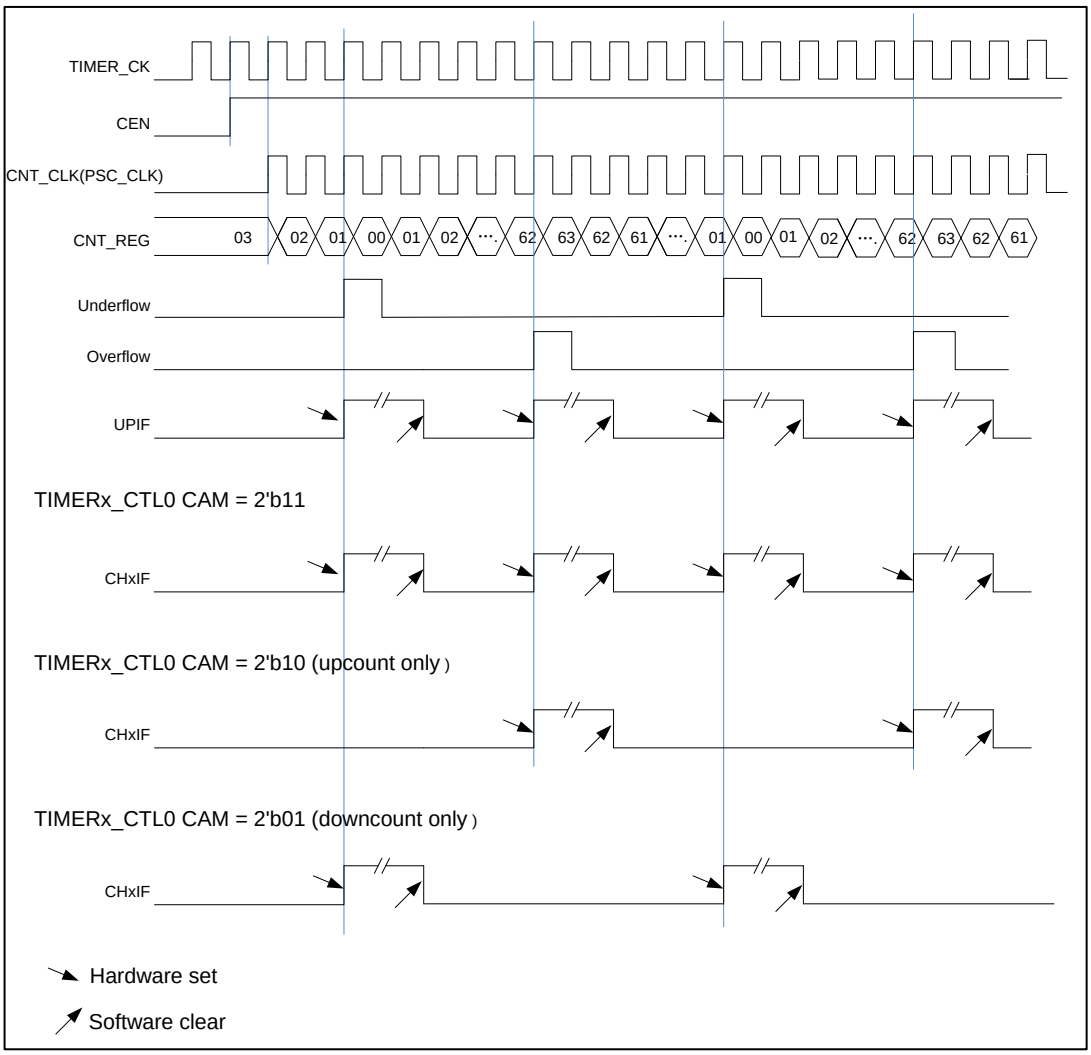
The UPIF bit in the TIMERx_INTF register can be set to 1 either when an underflow event or an overflow event occurs. While the CHxIF bit is associated with the value of CAM in TIMERx_CTL0. The details refer to ***Figure 18-57. Center-aligned counter timechart***.

If set the UPDIS bit in the TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto-reload register, prescaler register) are updated.

Figure 18-57. Center-aligned counter timechart show some examples of the counter behavior when TIMERx_CAR=0x63. TIMERx_PSC=0x0

Figure 18-57. Center-aligned counter timechart



Capture/compare channels

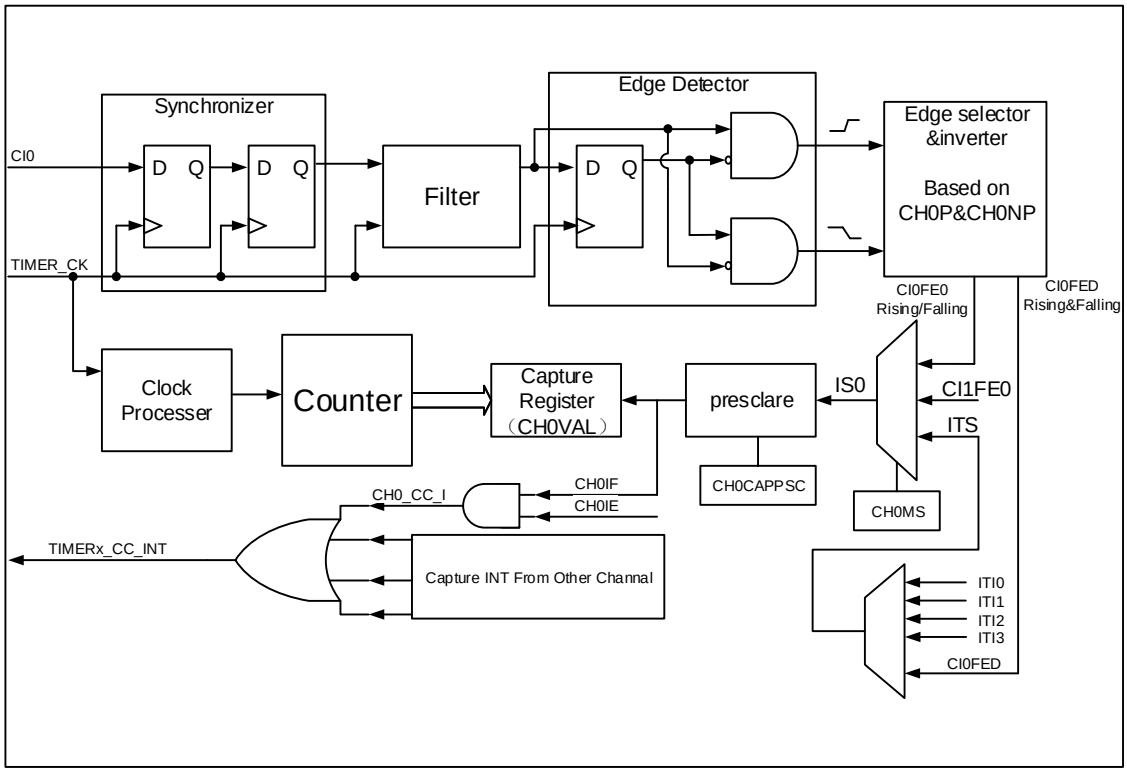
The general level1 timer has two independent channels which can be used as capture inputs or compare match outputs. Each channel is built around a channel capture compare register including an input stage, channel controller and an output stage.

- **Input capture mode**

Capture mode allows the channel to perform measurements such as pulse timing, frequency, period, duty cycle and so on. The input stage consists of a digital filter, a channel polarity selection, edge detection and a channel prescaler. When a selected edge occurs on the

channel input, the current value of the counter is captured into the TIMERx_CHxCV register, at the same time the CHxIF bit is set and the channel interrupt is generated if enabled by CHxIE = 1.

Figure 18-58. Input capture logic



First, the channel input signal (CIx) is synchronized to TIMER_CK domain, and then sampled by a digital filter to generate a filtered input signal. Then through the edge detector, the rising and fall edge are detected. You can select one of them by CHxP. One more selector is for the other channel and trig, controlled by CHxMS. Configuring the IC_prescaler enables an effective capture event after a number of input events. On the capture event, CHxVAL will restore the value of Counter.

So the process can be divided to several steps as below:

Step1: Filter configuration. (CHxCAPFLT in TIMERx_CHCTL0)
Based on the input signal and requested signal quality, configure compatible CHxCAPFLT.

Step2: Edge selection. (CHxP/CHxNP in TIMERx_CHCTL2)
Rising or falling edge, choose one by CHxP/CHxNP.

Step3: Capture source selection. (CHxMS in TIMERx_CHCTL0)
As soon as you select one input capture source by CHxMS, you have set the channel to input mode (CHxMS != 0x0) and TIMERx_CHxCV cannot be written any more.

Step4: Interrupt enable. (CHxIE and CHxDEN in TIMERx_DMAINTEN)
Enable the related interrupt; you can got the interrupt and DMA request.

Step5: Capture enable. (CHxEN in TIMERx_CHCTL2)

Result: When you wanted input signal is got, TIMERx_CHxCV will be set by Counter's value. And CHxIF is asserted. If the CHxIF is high, the CHxOF will be asserted also. The interrupt and DMA request will be asserted based on the your configuration of CHxIE and CHxDEN in TIMERx_DMAINTEN

Direct generation: If you want to generate a DMA request or Interrupt, you can set CHxG by software directly.

The input capture mode can be also used for pulse width measurement from signals on the TIMERx_CHx pins. For example, PWM signal connect to CI0 input. Select channel 0 capture signals to CI0 by setting CH0MS to 2'b01 in the channel control register (TIMERx_CHCTL0) and set capture on rising edge. Select channel 1 capture signal to CI0 by setting CH1MS to 2'b10 in the channel control register (TIMERx_CHCTL0) and set capture on falling edge. The counter set to restart mode and restart on channel 0 rising edge. Then the TIMERX_CH0CV can measure the PWM period and the TIMERx_CH1CV can measure the PWM duty.

- **Output compare mode**

In Output Compare mode, the TIMERx can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CHxVAL register of an output compare channel, the channel (n) output can be set, cleared, or toggled based on CHxCOMCTL. when the counter reaches the value in the CHxVAL register, the CHxIF bit is set and the channel (n) interrupt is generated if CHxIE = 1. And the DMA request will be assert, if CxCDE=1.

So the process can be divided to several steps as below:

Step1: Clock configuration. Such as clock source, clock prescaler and so on.

Step2: Compare mode configuration.
* Set the shadow enable mode by CHxCOMSEN
* Set the output mode (Set/Clear/Toggle) by CHxCOMCTL.
* Select the active high polarity by CHxP/CHxNP
* Enable the output by CHxEN

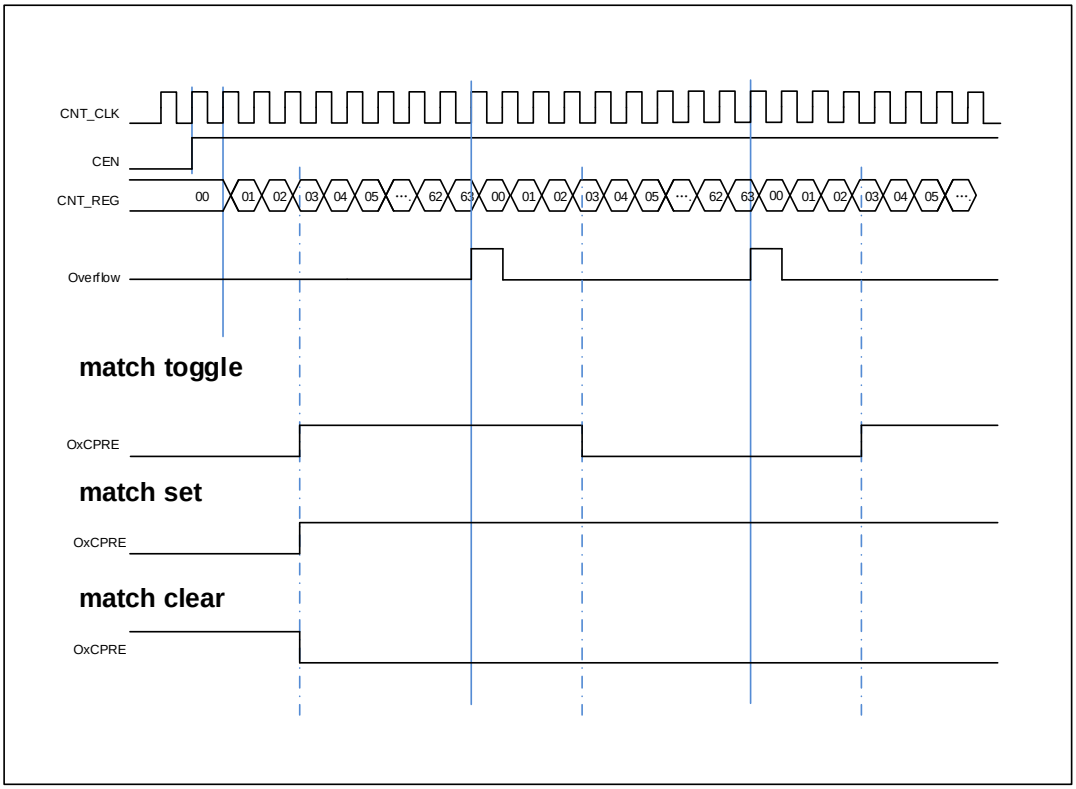
Step3: Interrupt/DMA-request enables configuration by CHxIE/CxCDE

Step4: Compare output timing configuration by TIMERx_CAR and TIMERx_CHxCV. About the CHxVAL, you can change it on the go to meet the waveform you expected.

Step5: Start the counter by CEN.

The timechart below show the three compare modes toggle/set/clear. CAR=0x63, CHxVAL=0x3

Figure 18-59. Output-compare under three modes



PWM mode

In the output PWM mode (by setting the CHxCOMCTL bits to 3'b110 (PWM mode0) or to 3'b 111(PWM mode1), the channel can outputs PWM waveform according to the TIMERx_CAR registers and TIMERx_CHxCV registers.

Based on the counter mode, we can also divide PWM into EAPWM (Edge aligned PWM) and CAPWM (Centre aligned PWM).

The EAPWM period is determined by TIMERx_CAR and duty cycle is determined by TIMERx_CHxCV. ***Figure 18-60. EAPWM timechart*** shows the EAPWM output and interrupts waveform.

The CAPWM period is determined by 2*TIMERx_CAR, and duty cycle is determined by 2*TIMERx_CHxCV. ***Figure 18-61. CAPWM timechart*** shows the CAPWM output and interrupt waveform.

If TIMERx_CHxCV is greater than TIMERx_CAR, the output will be always active under PWM mode0 (CHxCOMCTL==3'b110).
And if TIMERx_CHxCV is equal to zero, the output will be always inactive under PWM mode0 (CHxCOMCTL==3'b110).

Figure 18-60. EAPWM timechart

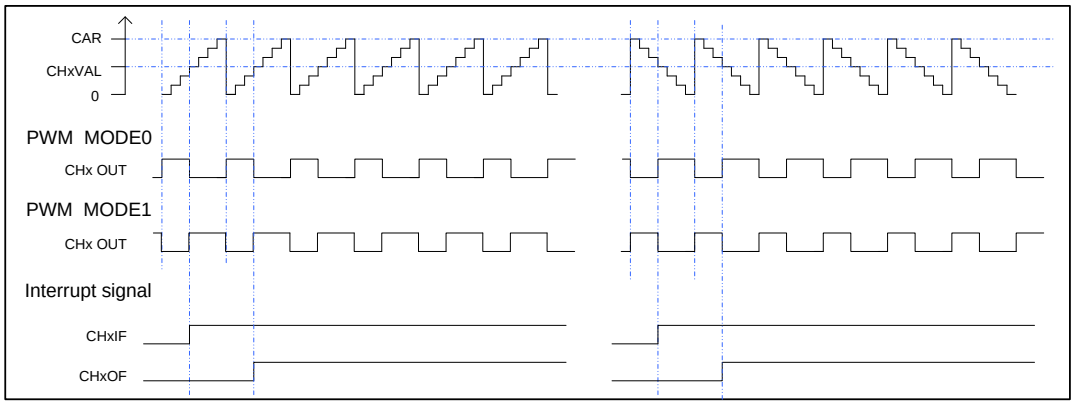


Figure 18-61. CAPWM timechart

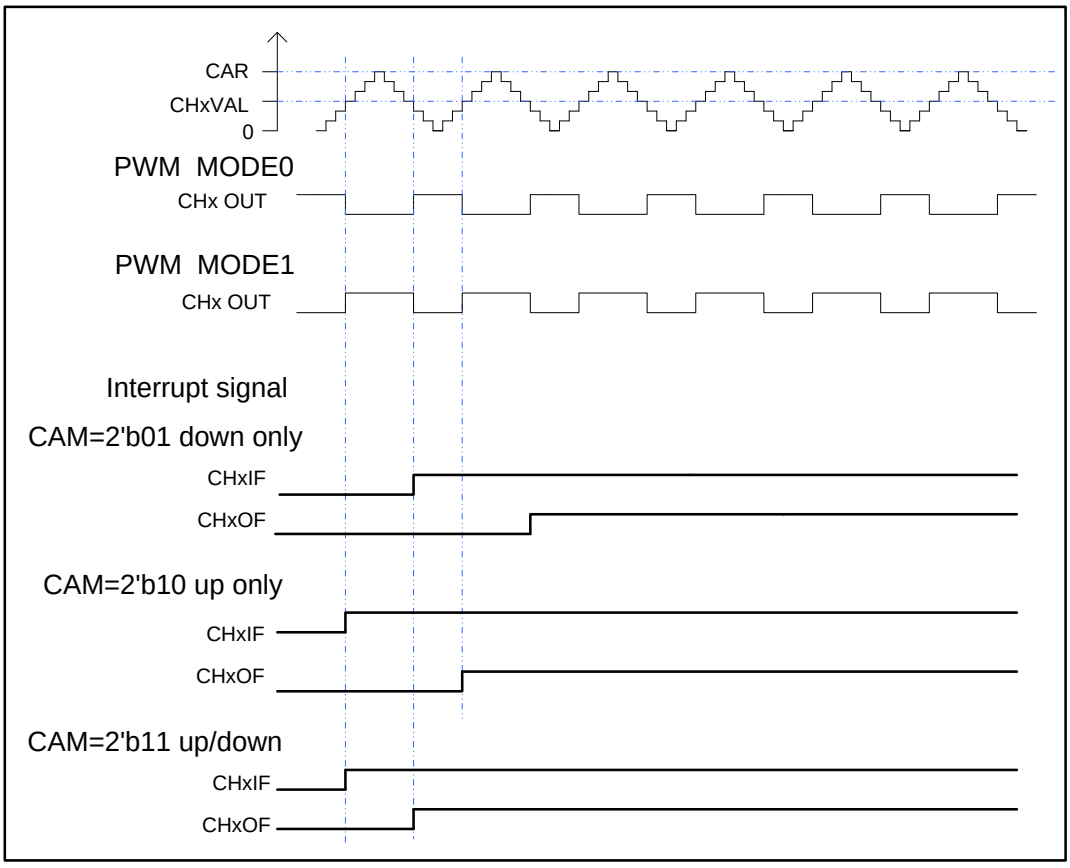


Channel output reference signal

When the TIMERx is used in the compare match output mode, the OxCPRE signal (Channel x Output prepare signal) is defined by setting the CHxCOMCTL filed. The OxCPRE signal has several types of output function. These include, keeping the original level by setting the CHxCOMCTL field to 0x00, set to 1 by setting the CHxCOMCTL field to 0x01, set to 0 by setting the CHxCOMCTL field to 0x02 or signal toggle by setting the CHxCOMCTL field to 0x03 when the counter value matches the content of the TIMERx_CHxCV register.

The PWM mode 0 and PWM mode 1 outputs are also another kind of OxCPRE output which

is setup by setting the CHxCOMCTL field to 0x06/0x07. In these modes, the OxCPRE signal level is changed according to the counting direction and the relationship between the counter value and the TIMERx_CHxCV content. With regard to a more detail description refer to the relative bit definition.

Another special function of the OxCPRE signal is a forced output which can be achieved by setting the CHxCOMCTL field to 0x04/0x05. Here the output can be forced to an inactive/active level irrespective of the comparison condition between the counter and the TIMERx_CHxCV values.

The OxCPRE signal can be forced to 0 when the ETIFE signal is derived from the external ETI pin and when it is set to a high level by setting the CHxCOMCEN bit to 1 in the TIMERx_CHCTL0 register. The OxCPRE signal will not return to its active level until the next update event occurs.

Slave controller

The TIMERx can be synchronized with a trigger in several modes including the Restart mode, the Pause mode and the Event mode which is selected by the SMC [2:0] in the TIMERx_SMCFG register. The trigger input of these modes can be selected by the TRGS [2:0] in the TIMERx_SMCFG register.

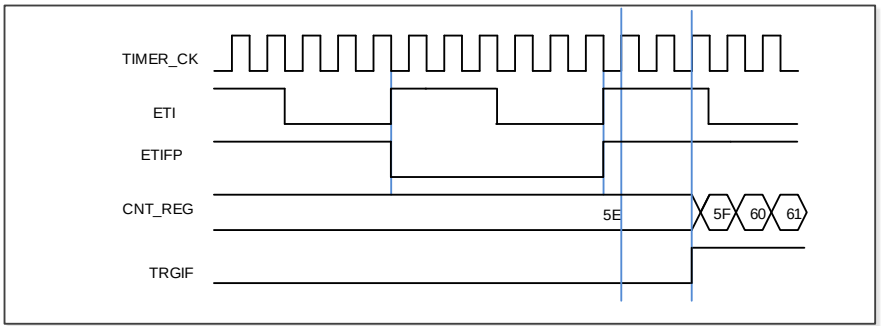
Table 18-7. Slave controller examples

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
LIST	SMC[2:0] 3'b100 (restart mode) 3'b101 (pause mode) 3'b110 (event mode)	TRGS[2:0] 000: ITI0 001: ITI1 010: ITI2 011: ITI3 100: CI0F_ED 101: CI0FE0 110: CI1FE1 111: ETIFP	If you choose the CI0FE0 or CI1FE1, configure the CHxP and CHxNP for the polarity selection and inversion. If you choose the ETIF, configure the ETP for polarity selection and inversion.	For the ITIx no filter and prescaler can be used. For the CIx, configure Filter by CHxCAPFLT, no prescaler can be used. For the ETIF, configure Filter by ETFC and Prescaler by ETPSC.
Exam1	Restart mode The counter can be clear and restart when a rising trigger input.	TRGS[2:0]=3'b000 ITI0 is the selection.	- For ITI0, no polarity selector can be used.	- For the ITI0, no filter and prescaler can be used.

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler
	Figure 18-62. Restart mode 			
Exam2	Pause mode The counter can be paused when the trigger input is low.	TRGS[2:0]=3'b101 CI0FE0 is the selection.	TI0S=0.（Non-xor） [CH0NP==0, CH0P==0] no inverted. Capture will be sensitive to the rising edge only.	Filter is bypass in this example.
	Figure 18-63. Pause mode 			
Exam3	Event mode The counter will start to count when a rising trigger input.	TRGS[2:0]=3'b111 ETIF is the selection.	ETP = 0 no polarity change.	ETPSC = 1, divided by 2. ETFC = 0 , no filter

	Mode Selection	Source Selection	Polarity Selection	Filter and Prescaler

Figure 18-64. Event mode



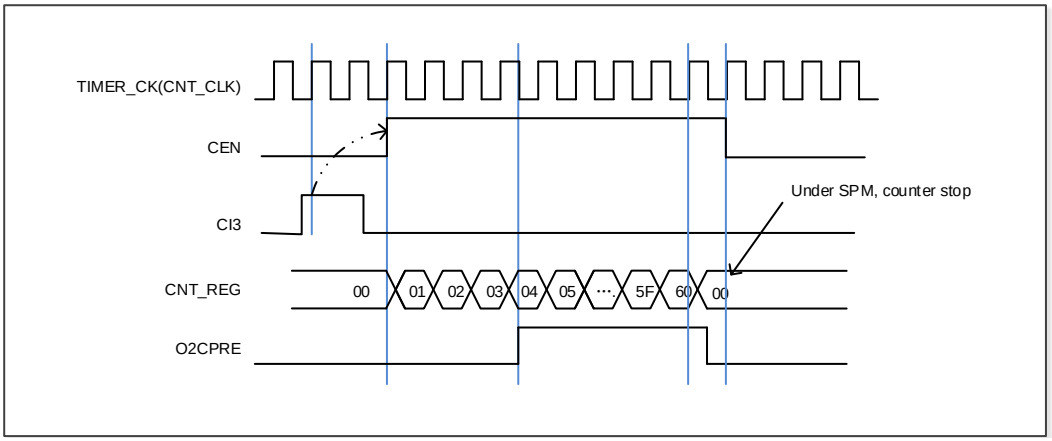
Single pulse mode

Single pulse mode is opposite to the repetitive mode, which can be enabled by setting SPM in TIMERx_CTL0. When you set SPM, the counter will be clear and stop when the next update event automatically. In order to get pulse waveform, you can set the TIMERx to PWM mode or compare by CHxCOMCTL.

Once the timer is set to operate in the single pulse mode, it is not necessary to set the timer enable bit CEN in the TIMERx_CTL0 register to 1 to enable the counter. The trigger to generate a pulse can be sourced from the trigger signals edge or by setting the CEN bit to 1 using software. Setting the CEN bit to 1 or a trigger from the trigger signals edge can generate a pulse and then keep the CEN bit at a high state until the update event occurs or the CEN bit is written to 0 by software. If the CEN bit is cleared to 0 using software, the counter will be stopped and its value held. If the CEN bit is automatically cleared to 0 by a hardware update event, the counter will be reinitialized.

In the single pulse mode, the trigger active edge which sets the CEN bit to 1 will enable the counter. However, there exist several clock delays to perform the comparison result between the counter value and the TIMERx_CHxCV value. In order to reduce the delay to a minimum value, user can set the CHxCOMFEN bit in each TIMERx_CHCTL0/1 register. After a trigger rising occurs in the single pulse mode, the OxCPRE signal will immediately be forced to the state which the OxCPRE signal will change to, as the compare match event occurs without taking the comparison result into account. The CHxCOMFEN bit is available only when the output channel is configured to operate in the PWM0 or PWM1 output mode and the trigger source is derived from the trigger signal.

Figure 18-65. Single pulse mode TIMERx_CHxCV = 0x04 TIMERx_CAR=0x60



Timers interconnection

Refer to ***Advanced timer (TIMERx, x=0, 7)***.

Timer debug mode

When the Cortex™-M3 halted, and the TIMERx_HOLD configuration bit in DBG_CTL2 register set to 1, the TIMERx counter stops.

18.3.5. Register definition

TIMER8 start address: 0x4001 4C00
TIMER11 start address: 0x4000 1800

Control register 0 (TIMERx_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CKDIV[1:0]		ARSE	CAM[1:0]		DIR	SPM	UPS	UPDIS	CEN
						rw		rw	rw		rw	rw	rw	rw	rw

Bits	Fields	Descriptions
15:10	Reserved	Must be kept at reset value
9:8	CKDIV[1:0]	Clock division The CKDIV bits can be configured by software to specify division ratio between the timer clock (TIMER_CK) and the dead-time and sampling clock (DTS), which is used by the dead-time generators and the digital filters. 00: $f_{DTS}=f_{TIMER\_CK}$ 01: $f_{DTS}= f_{TIMER\_CK}$ /2 10: $f_{DTS}= f_{TIMER\_CK}$ /4 11: Reserved
7	ARSE	Auto-reload shadow enable 0: The shadow register for TIMERx_CAR register is disabled 1: The shadow register for TIMERx_CAR register is enabled
6:5	CAM[1:0]	Counter aligns mode selection 00: No center-aligned mode (edge-aligned mode). The direction of the counter is specified by the DIR bit. 01: Center-aligned and counting down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting down, compare interrupt flag of channels can be set. 10: Center-aligned and counting up assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting up, compare interrupt flag of channels can be set. 11: Center-aligned and counting up/down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Both when the counter is counting up and counting

		down, compare interrupt flag of channels can be set. After the counter is enabled, CAM[1:0] cannot be switched from 0x00 to non 0x00.
4	DIR	Direction 0: Count up 1: Count down This bit is read only when the timer is configured in center-aligned mode or encoder mode.
3	SPM	Single pulse mode. 0: Counter continues after update event. 1: The CEN is cleared by hardware and the counter stops at next update event.
2	UPS	Update source This bit is used to select the update event sources by software. 0: When enabled, any of the following events generate an update interrupt or DMA request: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: When enabled, only counter overflow/underflow generates an update interrupt or DMA request.
1	UPDIS	Update disable. This bit is used to enable or disable the update event generation. 0: update event enable. The update event is generate and the buffered registers are loaded with their preloaded values when one of the following events occurs: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: update event disable. The buffered registers keep their value, while the counter and the prescaler are reinitialized if the UG bit is set or if the slave mode controller generates a hardware reset event.
0	CEN	Counter enable 0: Counter disable 1: Counter enable The CEN bit must be set by software when timer works in external clock, pause mode and encoder mode. While in event mode, the hardware can set the CEN bit automatically.

Slave mode configuration register (TIMERx_SMCFG)

Address offset: 0x08
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								MSM	TRGS[2:0]			Reserved	SMC[2:0]		
								rw	rw				rw		

Bits	Fields	Descriptions
15:8	Reserved	Must be kept at reset value
7	MSM	Master-slave mode This bit can be used to synchronize selected timers to begin counting at the same time. The TRGI is used as the start event, and through TRGO, timers are connected together. 0: Master-slave mode disable 1: Master-slave mode enable
6:4	TRGS[2:0]	Trigger selection This bit-field specifies which signal is selected as the trigger input, which is used to synchronize the counter. 000: Internal trigger input 0 (ITI0) 001: Internal trigger input 1 (ITI1) 010: Internal trigger input 2 (ITI2) 011: Internal trigger input 3 (ITI3) 100: CI0 edge flag (CI0F_ED) 101: channel 0 input Filtered output (CI0FE0) 110: channel 1 input Filtered output (CI1FE1) 111: External trigger input filter output(ETIFP) These bits must not be changed when slave mode is enabled.
3	Reserved	Must be kept at reset value.
2:0	SMC[2:0]	Slave mode control 000: Disable mode. The slave mode is disabled; The prescaler is clocked directly by the internal clock (TIMER_CK) when CEN bit is set high. 001: Quadrature decoder mode 0.The counter counts on CI1FE1 edge, while the direction depends on CI0FE0 level. 010: Quadrature decoder mode 1.The counter counts on CI0FE0 edge, while the direction depends on CI1FE1 level. 011: Quadrature decoder mode 2.The counter counts on both CI0FE0 and CI1FE1 edge, while the direction depends on each other. 100: Restart mode. The counter is reinitialized and the shadow registers are updated on the rising edge of the selected trigger input. 101: Pause mode. The trigger input enables the counter clock when it is high and disables the counter when it is low. 110: Event mode. A rising edge of the trigger input enables the counter. The counter cannot be disabled by the slave mode controller. 111: External clock mode0. The counter counts on the rising edges of the selected

trigger.

Interrupt enable register (TIMERx_DMAINTEN)

Address offset: 0x0C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

									rw				rw	rw	rw

Bits	Fields	Descriptions
15:7	Reserved	Must be kept at reset value.
6	TRGIE	Trigger interrupt enable 0: disabled 1: enabled
5:3	Reserved	Must be kept at reset value.
2	CH1IE	Channel 1 capture/compare interrupt enable 0: disabled 1: enabled
1	CH0IE	Channel 0 capture/compare interrupt enable 0: disabled 1: enabled
0	UPIE	Update interrupt enable 0: disabled 1: enabled

Interrupt flag register (TIMERx_INTF)

Address offset: 0x10
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					CH1OF	CH0OF	Reserved		TRGIF	Reserved			CH1IF	CH0IF	UPIF
					rc_w0	rc_w0			rc_w0				rc_w0	rc_w0	rc_w0

Bits	Fields	Descriptions
15:11	Reserved	Must be kept at reset value.
10	CH1OF	Channel 1 over capture flag Refer to CH0OF description
9	CH0OF	Channel 0 over capture flag When channel 0 is configured in input mode, this flag is set by hardware when a capture event occurs while CH0IF flag has already been set. This flag is cleared by software. 0: No over capture interrupt occurred 1: Over capture interrupt occurred
8:7	Reserved	Must be kept at reset value.
6	TRGIF	Trigger interrupt flag This flag is set by hardware on trigger event and cleared by software. When the slave mode controller is enabled in all modes but pause mode, an active edge on trigger input generates a trigger event. When the slave mode controller is enabled in pause mode both edges on trigger input generates a trigger event. 0: No trigger event occurred. 1: Trigger interrupt occurred.
5:3	Reserved	Must be kept at reset value.
2	CH1IF	Channel 1 ‘s capture/compare interrupt flag Refer to CH0IF description
1	CH0IF	Channel 0 ‘s capture/compare interrupt flag This flag is set by hardware and cleared by software. When channel 0 is in input mode, this flag is set when a capture event occurs. When channel 0 is in output mode, this flag is set when a compare event occurs. 0: No Channel 1 interrupt occurred 1: Channel 1 interrupt occurred
0	UPIF	Update interrupt flag This bit is set by hardware on an update event and cleared by software. 0: No update interrupt occurred 1: Update interrupt occurred

Software event generation register (TIMERx_SWEVG)

Address offset: 0x14
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									TRGG	Reserved.			CH1G	CH0G	UPG
									w				w	w	w

Bits	Fields	Descriptions
15:7	Reserved	Must be kept at reset value.
6	TRGG	Trigger event generation This bit is set by software and cleared by hardware automatically. When this bit is set, the TRGIF flag in TIMERx_STAT register is set, related interrupt or DMA transfer can occur if enabled. 0: No generate a trigger event 1: Generate a trigger event
5:3	Reserved	Must be kept at reset value.
2	CH1G	Channel 1's capture or compare event generation Refer to CH0G description
1	CH0G	Channel 0's capture or compare event generation This bit is set by software in order to generate a capture or compare event in channel 0, it is automatically cleared by hardware. When this bit is set, the CH1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. In addition, if channel 1 is configured in input mode, the current value of the counter is captured in TIMERx_CH0CV register, and the CH0OF flag is set if the CH0IF flag was already high. 0: No generate a channel 1 capture or compare event 1: Generate a channel 1 capture or compare event
0	UPG	This bit can be set by software, and cleared by hardware automatically. When this bit is set, the counter is cleared. The prescaler counter is cleared at the same time. 0: No generate an update event 1: Generate an update event

Channel control register 0 (TIMERx_CHCTL0)

Address offset: 0x18

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

CH1COMCEN	CH1COMCTL[2:0]			CH1COMSEN	CH1COMFEN	CH1MS[1:0]		CH0COMCEN	CH0COMCTL[2:0]			CH0COMSEN	CH0COMFEN	CH0MS[1:0]	
CH1CAPFLT[3:0]				CH1CAPPSC[1:0]				CH0CAPFLT[3:0]				CH0CAPPSC[1:0]			
rw				rw		rw		rw				rw		rw	

Output compare mode:

Bits	Fields	Descriptions
15	CH1COMCEN	Channel 1 output compare clear enable Refer to CH0COMCEN description
14:12	CH1COMCTL[2:0]	Channel 1 compare output control Refer to CH0COMCTL description
11	CH1COMSEN	Channel 1 output compare shadow enable Refer to CH0COMSEN description
10	CH1COMFEN	Channel 1 output compare fast enable Refer to CH0COMSEN description
9:8	CH1MS[1:0]	Channel 1 mode selection This bit-field specifies the direction of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH1EN bit in TIMERx_CHCTL2 register is reset). 00: Channel 1 is configured as output 01: Channel 1 is configured as input, IS1 is connected to CI0FE1 10: Channel 1 is configured as input, IS1 is connected to CI1FE1 11: Channel 1 is configured as input, IS1 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.
7	CH0COMCEN	Channel 0 output compare clear enable. When this bit is set, the O0CPRE signal is cleared when High level is detected on ETIF input. 0: Channel 0 output compare clear disable 1: Channel 0 output compare clear enable
6:4	CH0COMCTL[2:0]	Channel 0 compare output control This bit-field controls the behavior of the output reference signal O0CPRE which drives CH0_O and CH0_ON. O0CPRE is active high, while CH0_O and CH0_ON active level depends on CH0P and CH0NP bits. 000: Frozen. The O0CPRE signal keeps stable, independent of the comparison between the register TIMERx_CH0CV and the counter TIMERx_CNT. 001: Set the channel output. O0CPRE signal is forced high when the counter matches the output compare register TIMERx_CH0CV. 010: Clear the channel output. O0CPRE signal is forced low when the counter matches the output compare register TIMERx_CH0CV. 011: Toggle on match. O0CPRE toggles when the counter matches the output compare register TIMERx_CH0CV. 100: Force low. O0CPRE is forced low level. 101: Force high. O0CPRE is forced high level. 110: PWM mode0. When counting up, O0CPRE is high as long as the counter is

smaller than TIMERx_CH0CV, otherwise it is low. When counting down, O0CPRE is low as long as the counter is larger than TIMERx_CH0CV, otherwise it is high.
111: PWM mode1. When counting up, O0CPRE is low as long as the counter is smaller than TIMERx_CH0CV,otherwise it is high. When counting down, O0CPRE is high as long as the counter is larger than TIMERx_CH0CV,otherwise it is low.
When configured in PWM mode, the O0CPRE level changes only when the output compare mode switches from “frozen” mode to “PWM” mode or when the result of the comparison changes.
This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00(COMPARE MODE).

3	CH0COMSEN	Channel 0 compare output shadow enable When this bit is set, the shadow register of TIMERx_CH0CV register, which updates at each update event, will be enabled. 0: Channel 0 output compare shadow disable 1: Channel 0 output compare shadow enable The PWM mode can be used without validating the shadow register only in single pulse mode (SPM bit in TIMERx_CTL0 register is set). This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00.
2	CH0COMFEN	Channel 0 output compare fast enable When this bit is set, the effect of an event on the trigger in input on the capture/compare output will be accelerated if the channel is configured in PWM0 or PWM1 mode. The output channel will treat an active edge on the trigger input as a compare match, and CH0_O is set to the compare level independently from the result of the comparison. 0: Channel 0 output quickly compare disable. The minimum delay from an edge on the trigger input to activate CH0_O output is 5 clock cycles. 1: Channel 0 output quickly compare enable. The minimum delay from an edge on the trigger input to activate CH0_O output is 3 clock cycles.
1:0	CH0MS[1:0]	Channel 0 I/O mode selection This bit-field specifies the work mode of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH0EN bit in TIMERx_CHCTL2 register is reset).). 00: Channel 0 is configured as output 01: Channel 0 is configured as input, IS0 is connected to CI0FE0 10: Channel 0 is configured as input, IS0 is connected to CI1FE0 11: Channel 0 is configured as input, IS0 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.

Input capture mode:

Bits	Fields	Descriptions
15:12	CH1CAPFLT[3:0]	Channel 1 input capture filter control Refer to CH0CAPFLT description
11:10	CH1CAPPSC[1:0]	Channel 1 input capture prescaler Refer to CH0CAPPSC description
9:8	CH1MS[1:0]	Channel 1 mode selection Same as Output compare mode
7:4	CH0CAPFLT[3:0]	Channel 0 input capture filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample CI0 input signal and the length of the digital filter applied to CI0. 0000: Filter disabled, $f_{SAMP}=f_{DTS}$, N=1 0001: $f_{SAMP}=f_{TIMER\_CK}$, N=2 0010: $f_{SAMP}= f_{TIMER\_CK}$, N=4 0011: $f_{SAMP}= f_{TIMER\_CK}$, N=8 0100: $f_{SAMP}=f_{DTS}/2$, N=6 0101: $f_{SAMP}=f_{DTS}/2$, N=8 0110: $f_{SAMP}=f_{DTS}/4$, N=6 0111: $f_{SAMP}=f_{DTS}/4$, N=8 1000: $f_{SAMP}=f_{DTS}/8$, N=6 1001: $f_{SAMP}=f_{DTS}/8$, N=8 1010: $f_{SAMP}=f_{DTS}/16$, N=5 1011: $f_{SAMP}=f_{DTS}/16$, N=6 1100: $f_{SAMP}=f_{DTS}/16$, N=8 1101: $f_{SAMP}=f_{DTS}/32$, N=5 1110: $f_{SAMP}=f_{DTS}/32$, N=6 1111: $f_{SAMP}=f_{DTS}/32$, N=8
3:2	CH0CAPPSC[1:0]	Channel 0 input capture prescaler This bit-field specifies the factor of the prescaler on channel 0 input. The prescaler is reset when CH0EN bit in TIMERx_CHCTL2 register is clear. 00: Prescaler disable, capture is done on each channel input edge 01: Capture is done every 2 channel input edges 10: Capture is done every 4 channel input edges 11: Capture is done every 8 channel input edges
1:0	CH0MS[1:0]	Channel 0 mode selection Same as Output compare mode

Channel control register 2 (TIMERx_CHCTL2)

Address offset: 0x20

Reset value: 0x0000

This register can be accessed by half-word(16-bit) or word(32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Fields	Descriptions
15:6	Reserved	Must be kept at reset value
5	CH1P	Channel 1 capture/compare function polarity Refer to CH0P description
4	CH1EN	Channel 1 capture/compare function enable Refer to CH1EN description
3	CH0NP	Channel 0 complementary output polarity When channel 0 is configured in output mode, this bit should be keep reset value. When channel 0 is configured in input mode, In conjunction with CH0P, this bit is used to define the polarity of CI0. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 or 10.
2	Reserved	Must be kept at reset value
1	CH0P	Channel 0 capture/compare function polarity When channel 0 is configured in output mode, this bit specifies the output signal polarity. 0: Channel 0 active high 1: Channel 0 active low When channel 0 is configured in input mode, this bit specifies the CI0 signal polarity. [CH0NP, CH0P] will select the active trigger or capture polarity for CI0FE0 or CI1FE0. [CH0NP==0, CH0P==0]: CIxFE0's rising edge is the active signal for capture or trigger operation in slave mode. And CIxFE0 will not be inverted. [CH0NP==0, CH0P==1]: CIxFE0's falling edge is the active signal for capture or trigger operation in slave mode. And CIxFE0 will be inverted. [CH0NP==1, CH0P==0]: Reserved. [CH0NP==1, CH0P==1]: CIxFE0's falling and rising edge are both the active signal for capture or trigger operation in slave mode. And CIxFE0 will be not inverted.
0	CH0EN	Channel 0 capture/compare function enable When channel 0 is configured in output mode, setting this bit enables CH0_O signal in active state. When channel 0 is configured in input mode, setting this bit enables the capture event in channel0. 0: Channel 0 disabled

1: Channel 0 enabled

Counter register (TIMERx_CNT)

Address offset: 0x24
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CNT[15:0]	This bit-filed indicates the current counter value. Writing to this bit-filed can change the value of the counter.

Prescaler register (TIMERx_PSC)

Address offset: 0x28
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw															

Bits	Fields	Descriptions
15:0	PSC[15:0]	Prescaler value of the counter clock The PSC clock is divided by (PSC+1) to generate the counter clock. The value of this bit-filed will be loaded to the corresponding shadow register at every update event.

Counter auto reload register (TIMERx_CAR)

Address offset: 0x2C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

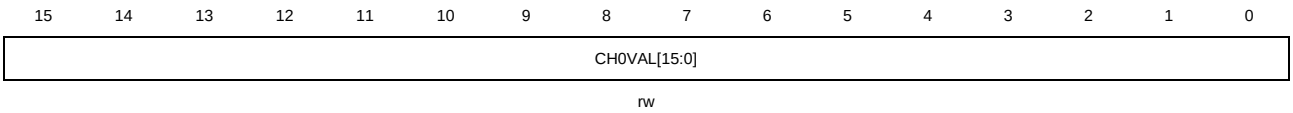
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CARL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CARL[15:0]	Counter auto reload value This bit-filed specifies the auto reload value of the counter.

Channel 0 capture/compare value register (TIMERx_CH0CV)

Address offset: 0x34
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

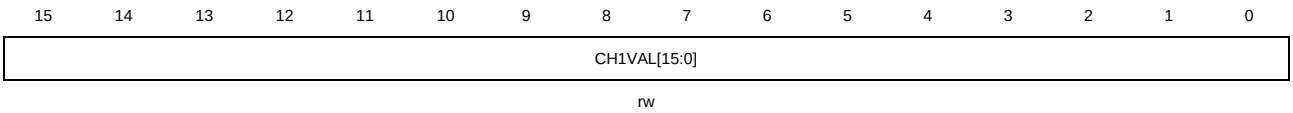


Bits	Fields	Descriptions
15:0	CH0VAL[15:0]	Capture or compare value of channel0 When channel 0 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 0 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

Channel 1 capture/compare value register (TIMERx_CH1CV)

Address offset: 0x38
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:0	CH1VAL[15:0]	Capture or compare value of channel1 When channel 1 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 1 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

18.4. General level2 timer (TIMERx, x=9, 10, 12, 13)

18.4.1. Overview

The general level2 timer module (Timer9, 10, 12, 13) is a one-channel timer that supports input capture, output compare. They can generate PWM signals to control motor or be used for power management applications. The general level2 time reference is a 16-bit counter that can be used as an unsigned counter.

In addition, the general level2 timers can be programmed and be used to count or time external events that drive other Timers.

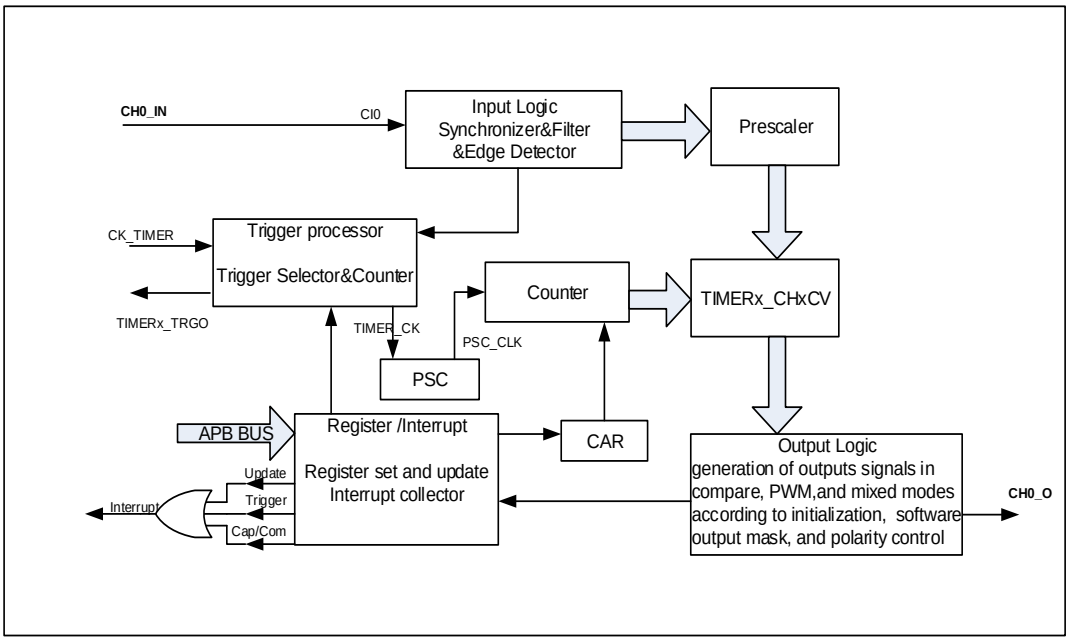
18.4.2. Characteristics

- Total channel num: 1.
- Counter width: 16bit.
- Source of count clock is selectable:
  internal clock, internal trigger, external input, external trigger.
- Multiple counter modes: count up, count down, count up/down.
- Programmable prescaler: 16 bit. Factor can be changed on the go.
- Each channel is user-configurable:
  Input capture mode, output compare mode and programmable PWM mode.
- Auto-reload function.
- Interrupt output on: update, trigger event, and compare/capture event.

18.4.3. Block diagram

Figure 18-66. General level2 timer block diagram provides details on the internal configuration of the general level2 timer.

Figure 18-66. General level2 timer block diagram



18.4.4. Function overview

Clock selection

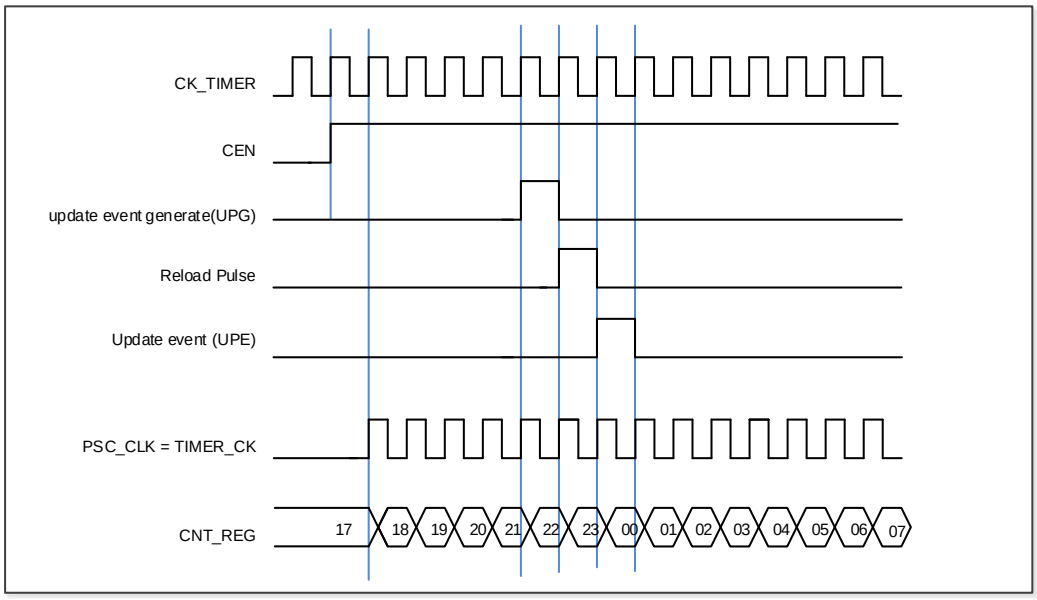
The general level2 TIMER can only being clocked by the CK_TIMER.

- Internal timer clock CK_TIMER which is from module RCU

The general level2 TIMER has only one clock source which is the internal CK_TIMER, used to drive the counter prescaler. When the CEN is set, the CK_TIMER will be divided by PSC value to generate PSC_CLK.

The TIMER_CK, driven counter's prescaler to count, is equal to CK_TIMER which is from RCU

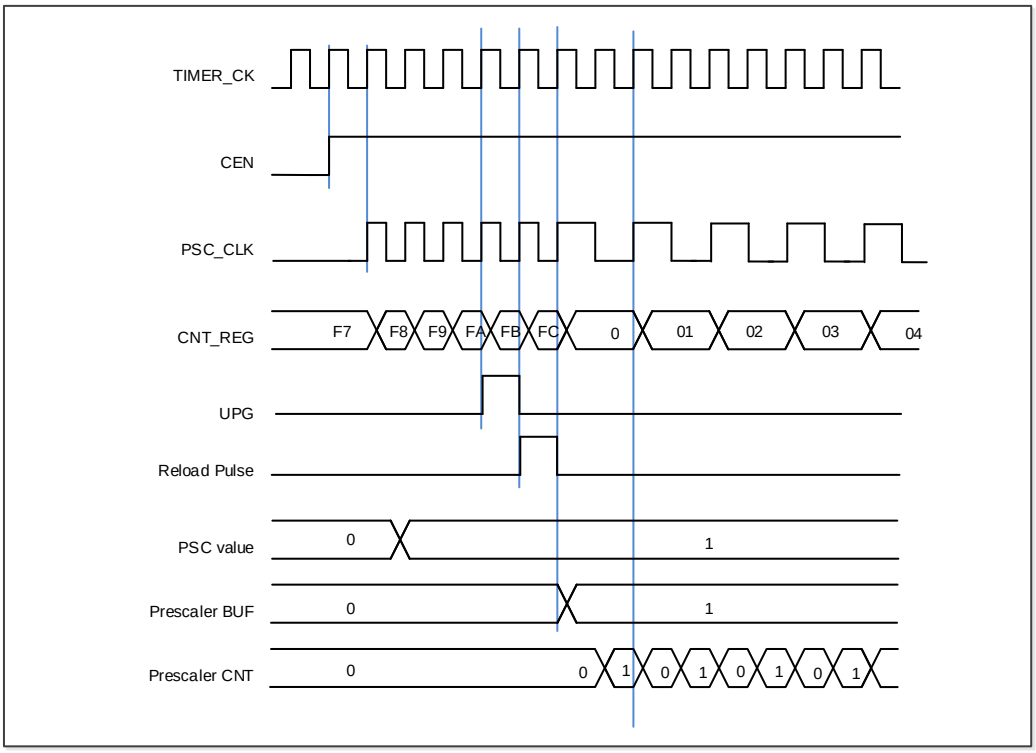
Figure 18-67. Normal mode, internal clock divided by 1



Prescaler

The prescaler can divide the timer clock (TIMER_CK) to the counter clock (PSC_CLK by any factor between 1 and 65536. It is controlled through prescaler register (TIMERx_PSC) which can be changed on the go but be taken into account at the next update event.

Figure 18-68. Counter timing diagram with prescaler division change from 1 to 2



Up counting mode

In this mode, the counter counts up continuously from 0 to the counter-reload value, which is defined in the TIMERx_CAR register, in a count-up direction. Once the counter reaches the counter reload value, the counter restarts to count once again from 0. The update event is generated at each counter overflow. The counting direction bit DIR in the TIMERx_CTL1 register should be set to 0 for the up counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to 0 and generates an update event.

If the UPDIS bit in TIMERx_CTL0 register is set, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior for different clock prescaler factor when TIMERx_CAR=0x63.

Figure 18-69. Up-counter timechart, PSC=0/1

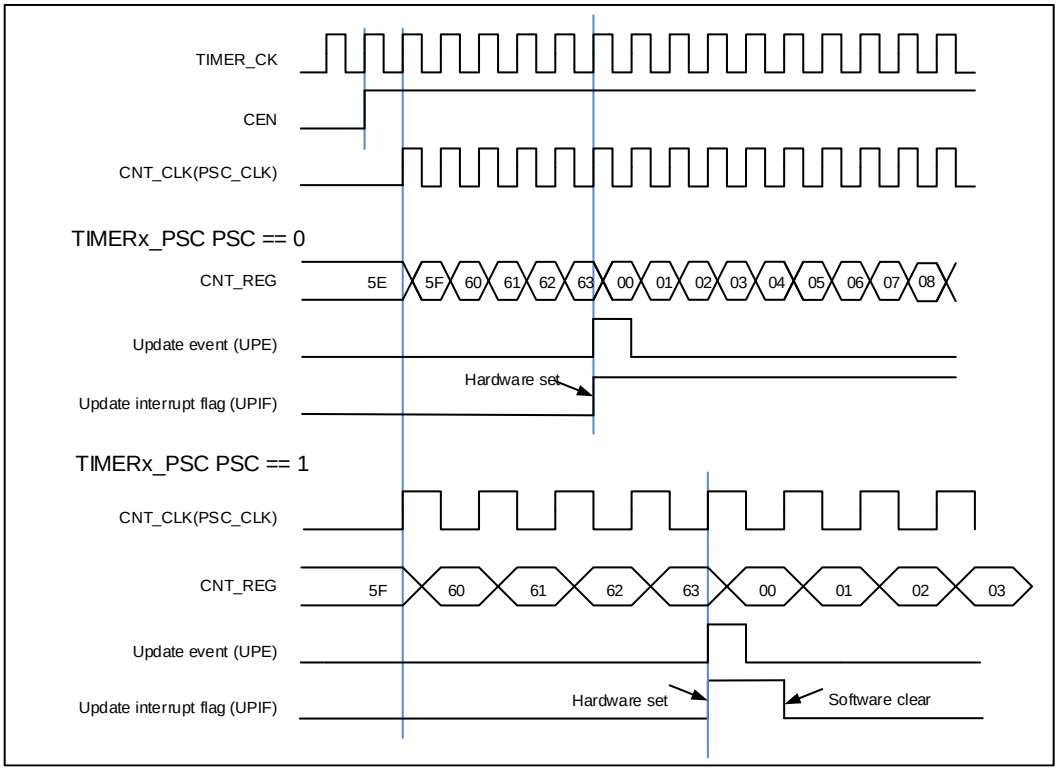


Figure 18-70. Up-counter timechart, change TIMERx_CAR on the go

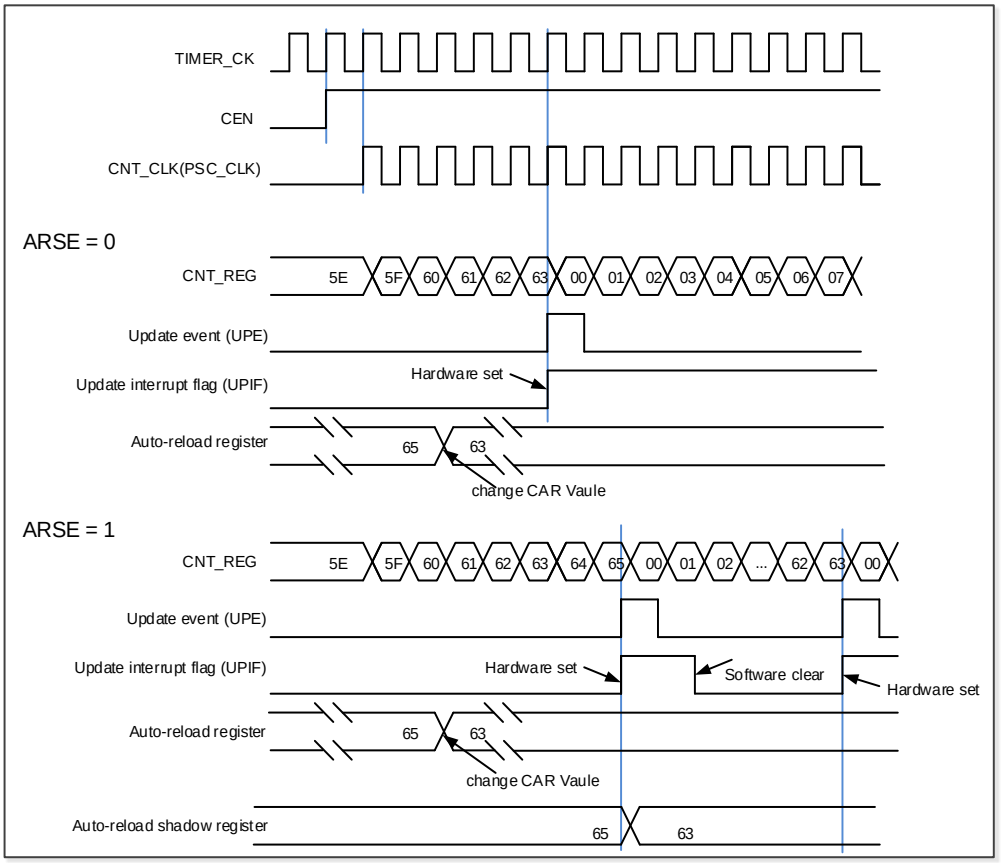

Down counting mode

In this mode, the counter counts down continuously from the counter-reload value, which is defined in the TIMERx_CAR register, to 0 in a count-down direction. Once the counter reaches to 0, the counter restarts to count again from the counter-reload value. If the repetition counter is set, the update event will be generated after (TIMERx_CREP+1) times of underflow. Otherwise the update event is generated each time when underflows. The counting direction bit DIR in the TIMERx_CTL0 register should be set to 1 for the down-counting mode.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to the counter-reload value and generates an update event.

If set the UPDIS bit in TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior in different clock frequencies when TIMERx_CAR=0x63.

Figure 18-71. Down-counter timechart, PSC=0/1

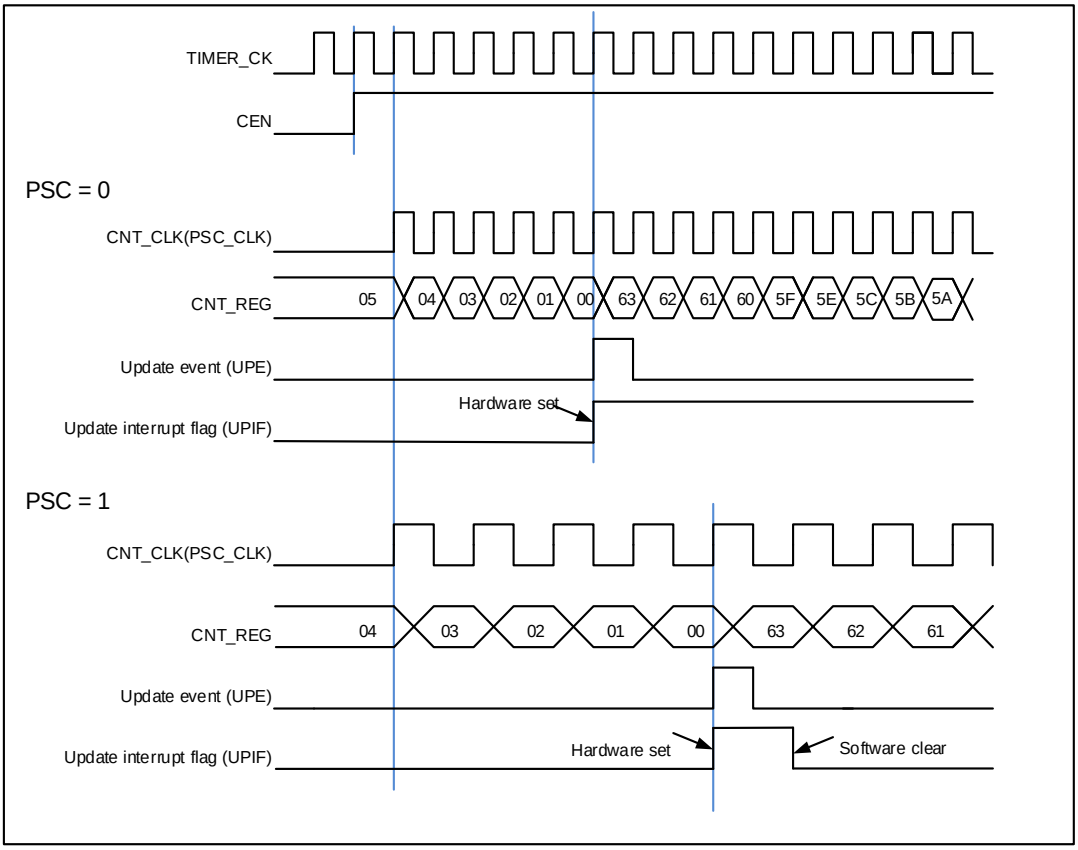

Figure 18-72. Down-counter timechart, change TIMERx_CAR on the go

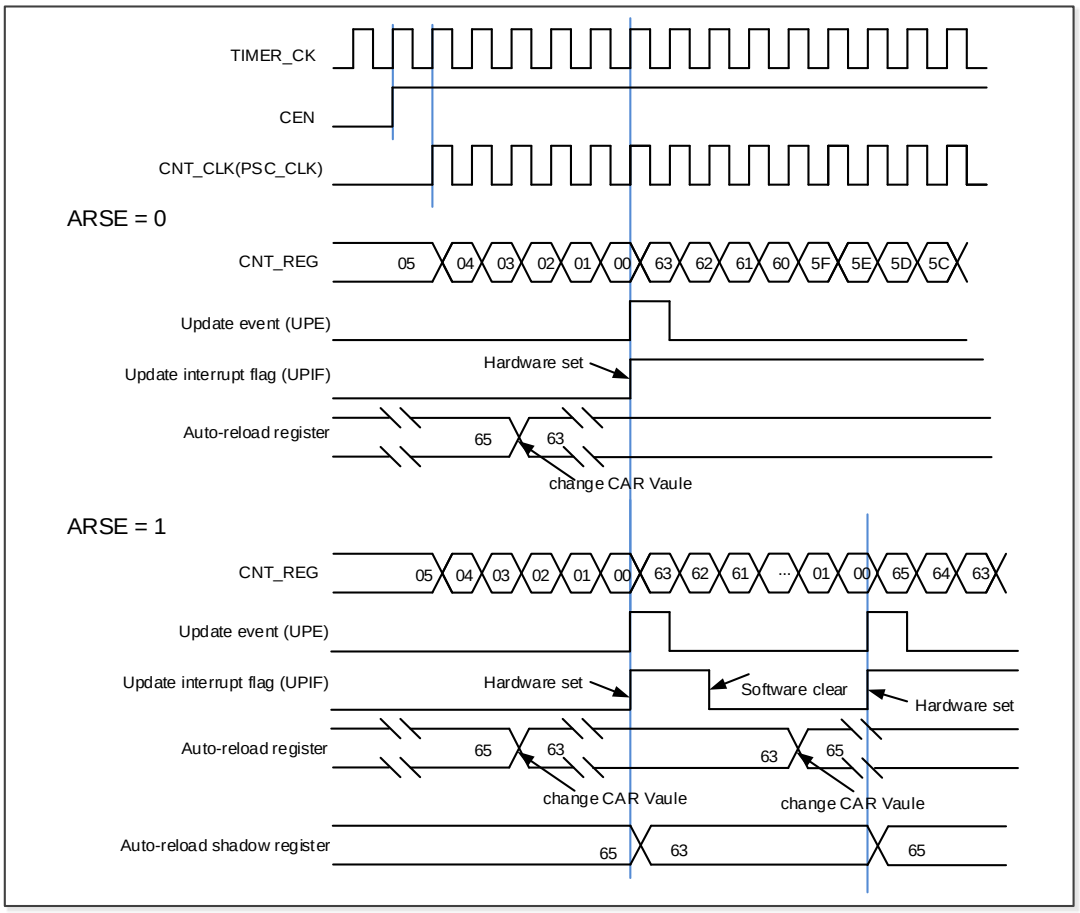


Center-aligned counting mode

In the center-aligned counting mode, the counter counts up from 0 to the counter-reload value and then counts down to 0 alternatively. The Timer module generates an overflow event when the counter counts to the counter-reload value subtract 1 in the up-counting direction and generates an underflow event when the counter counts to 1 in the down-counting direction. The counting direction bit DIR in the TIMERx_CTL0 register is read-only and indicates the counting direction when in the center-aligned mode. The counting direction is updated by hardware automatically.

Setting the UPG bit in the TIMERx_SWEVG register will initialize the counter value to 0 and generates an update event irrespective of whether the counter is counting up or down in the center-align counting mode.

The UPIF bit in the TIMERx_INTF register can be set to 1 either when an underflow event or an overflow event occurs. While the CHxIF bit is associated with the value of CAM in TIMERx_CTL0. The details refer to ***Figure 18-73. Center-aligned counter timechart***.

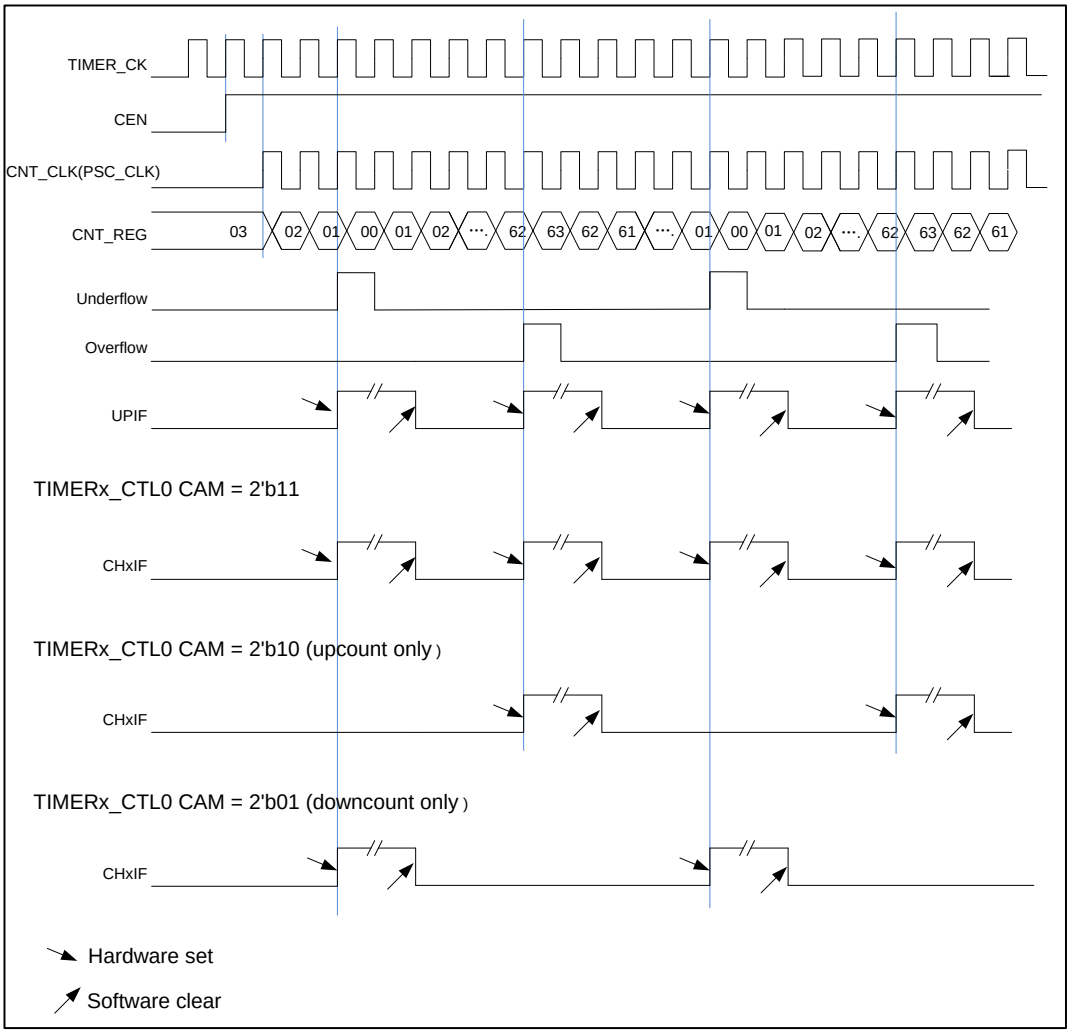
If set the UPDIS bit in the TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto-reload register,

prescaler register) are updated.

Figure 18-73. Center-aligned counter timechart show some examples of the counter behavior when TIMERx_CAR=0x63. TIMERx_PSC=0x0

Figure 18-73. Center-aligned counter timechart



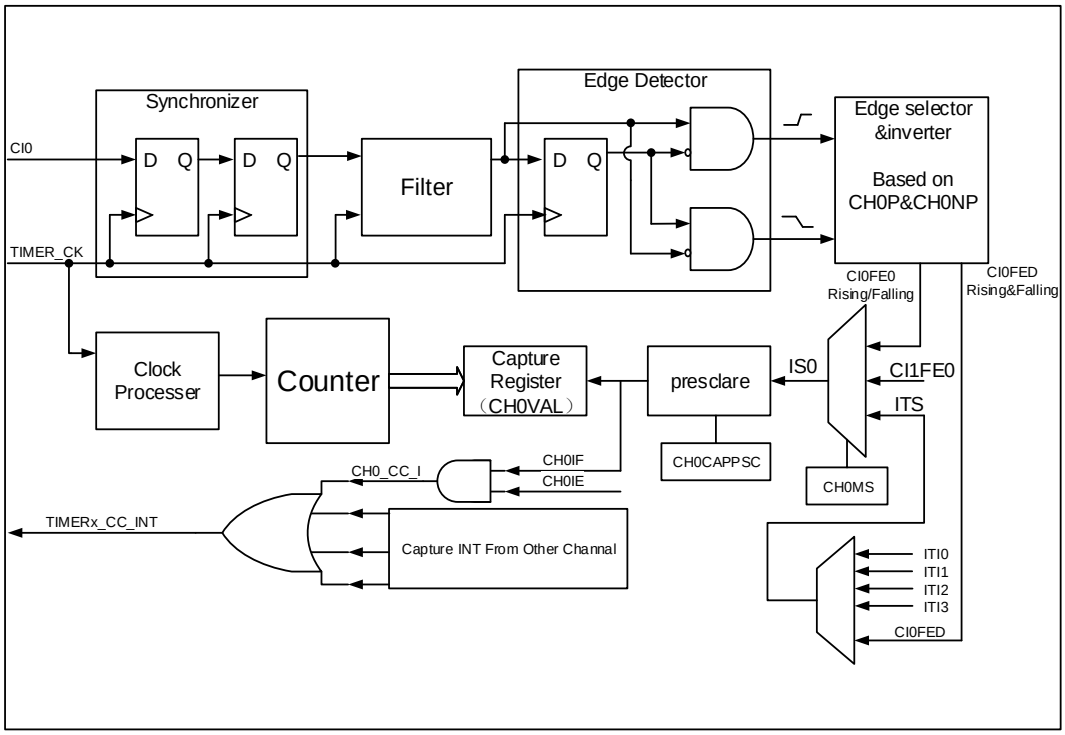
Capture/compare channels

The general level2 timer has only one independent channel which can be used as capture inputs or compare match outputs. This channel is built around a channel capture compare register including an input stage, channel controller and an output stage.

■ Input capture mode

Capture mode allows the channel to perform measurements such as pulse timing, frequency, period, duty cycle and so on. The input stage consists of a digital filter, a channel polarity selection, edge detection and a channel prescaler. When a selected edge occurs on the channel input, the current value of the counter is captured into the TIMERx_CHxCV register, at the same time the CHxIF bit is set and the channel interrupt is generated if enabled by CHxIE = 1.

Figure 18-74. Input capture logic



First, the channel input signal (CIx) is synchronized to TIMER_CK domain, and then sampled by a digital filter to generate a filtered input signal. Then through the edge detector, the rising and fall edge are detected. You can select one of them by CHxP. One more selector is for the other channel and trig, controlled by CHxMS. Configuring the IC_prescaler enables an effective capture event after a number of input events. On the capture event, CHxVAL will restore the value of Counter.

So the process can be divided to several steps as below:

Step1: Filter configuration. (CHxCAPFLT in TIMERx_CHCTL0)
Based on the input signal and requested signal quality, configure compatible CHxCAPFLT.

Step2: Edge selection. (CHxP/CHxNP in TIMERx_CHCTL2)
Rising or falling edge, choose one by CHxP/CHxNP.

Step3: Capture source selection. (CHxMS in TIMERx_CHCTL0)
As soon as you select one input capture source by CHxMS, you have set the channel to input mode (CHxMS != 0x0) and TIMERx_CHxCV cannot be written any more.

Step4: Interrupt enable. (CHxIE in TIMERx_DMAINTEN)
Enable the related interrupt ; you can got the interrupt.

Step5: Capture enable. (CHxEN in TIMERx_CHCTL2)

Result: When you wanted input signal is got, TIMERx_CHxCV will be set by Counter's value. And CHxIF is asserted. If the CHxIF is high, the CHxOF will be asserted also. The interrupt will be asserted based on the your configuration of CHxIE in

TIMERx_DMAINTEN

Direct generation: If you want to generate a DMA request or Interrupt, you can set CHxG by software directly.

The input capture mode can be also used for pulse width measurement from signals on the TIMERx_CHx pins. For example, PWM signal connect to CI0 input. Select channel 0 capture signals to CI0 by setting CH0MS to 2'b01 in the channel control register (TIMERx_CHCTL0) and set capture on rising edge. Select channel 1 capture signal to CI0 by setting CH1MS to 2'b10 in the channel control register (TIMERx_CHCTL0) and set capture on falling edge. The counter set to restart mode and restart on channel 0 rising edge. Then the TIMERX_CH0CV can measure the PWM period and the TIMERx_CH1CV can measure the PWM duty.

- **Output compare mode**

In Output Compare mode, the TIMERx can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CHxVAL register of an output compare channel, the channel (n) output can be set, cleared, or toggled based on CHxCOMCTL. when the counter reaches the value in the CHxVAL register, the CHxIF bit is set and the channel (n) interrupt is generated if CHxIE = 1.

So the process can be divided to several steps as below:

Step1: Clock configuration. Such as clock source, clock prescaler and so on.

Step2: Compare mode configuration.

* Set the shadow enable mode by CHxCOMSEN
* Set the output mode (Set/Clear/Toggle) by CHxCOMCTL.
* Select the active high polarity by CHxP/CHxNP
* Enable the output by CHxEN

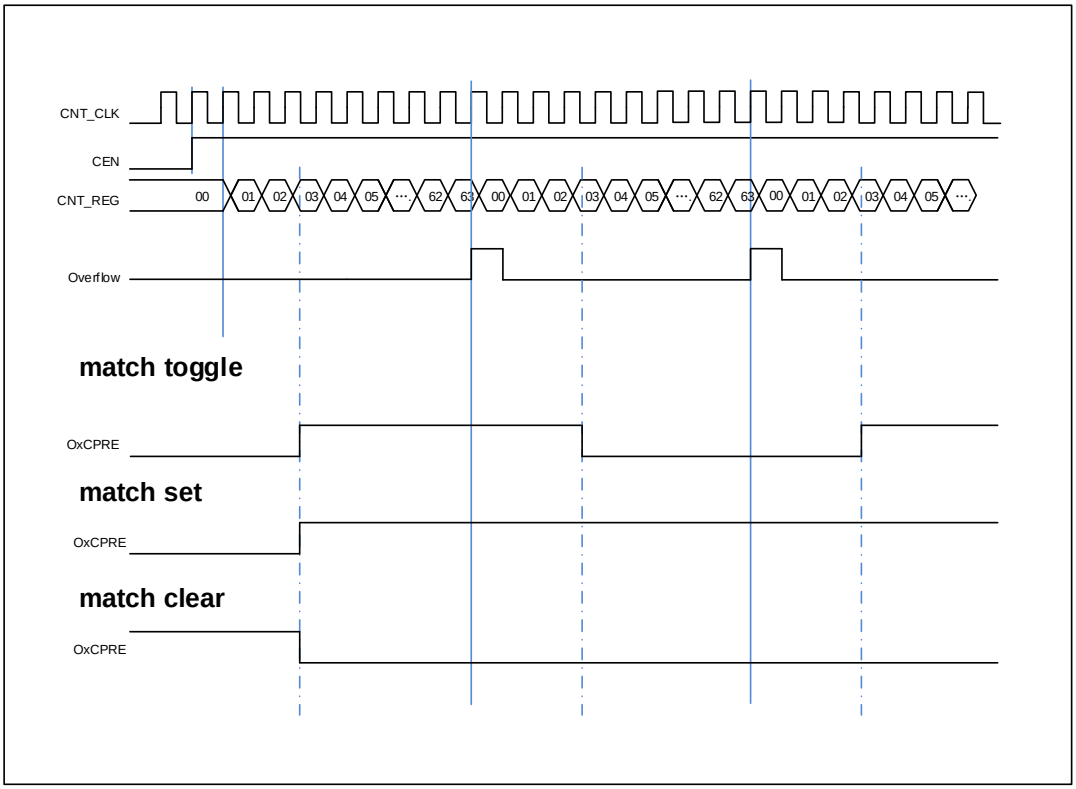
Step3: Interrupt/DMA-request enables configuration by CHxIE

Step4: Compare output timing configuration by TIMERx_CAR and TIMERx_CHxCV. About the CHxVAL, you can change it on the go to meet the waveform you expected.

Step5: Start the counter by CEN.

The timechart below show the three compare modes toggle/set/clear. CAR=0x63, CHxVAL=0x3

Figure 18-75. Output-compare under three modes



Channel output reference signal

When the TIMERx is used in the compare match output mode, the OxCPRE signal (Channel x Output prepare signal) is defined by setting the CHxCOMCTL filed. The OxCPRE signal has several types of output function. These include, keeping the original level by setting the CHxCOMCTL field to 0x00, set to 1 by setting the CHxCOMCTL field to 0x01, set to 0 by setting the CHxCOMCTL field to 0x02 or signal toggle by setting the CHxCOMCTL field to 0x03 when the counter value matches the content of the TIMERx_CHxCV register.

The PWM mode 0 and PWM mode 1 outputs are also another kind of OxCPRE output which is setup by setting the CHxCOMCTL field to 0x06/0x07. In these modes, the OxCPRE signal level is changed according to the counting direction and the relationship between the counter value and the TIMERx_CHxCV content. With regard to a more detail description refer to the relative bit definition.

Another special function of the OxCPRE signal is a forced output which can be achieved by setting the CHxCOMCTL field to 0x04/0x05. Here the output can be forced to an inactive/active level irrespective of the comparison condition between the counter and the TIMERx_CHxCV values.

The OxCPRE signal can be forced to 0 when the ETIFE signal is derived from the external ETI pin and when it is set to a high level by setting the CHxCOMCEN bit to 1 in the TIMERx_CHCTL0 register. The OxCPRE signal will not return to its active level until the next update event occurs.

Timer debug mode

When the Cortex™-M3 halted, and the TIMERx_HOLD configuration bit in DBG_CTL2 register set to 1, the TIMERx counter stops.

18.4.5. Register definition

TIMER9 start address: 0x4001 5000

TIMER10 start address: 0x4001 5400

TIMER12 start address: 0x4000 1C00

TIMER13 start address: 0x4000 2000

Control register 0 (TIMERx_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Fields	Descriptions
15:10	Reserved	Must be kept at reset value
9:8	CKDIV[1:0]	Clock division The CKDIV bits can be configured by software to specify division ratio between the timer clock (TIMER_CK) and the dead-time and sampling clock (DTS), which is used by the dead-time generators and the digital filters. 00: $f_{DTS}=f_{TIMER\_CK}$ 01: $f_{DTS}= f_{TIMER\_CK}$ /2 10: $f_{DTS}= f_{TIMER\_CK}$ /4 11: Reserved
7	ARSE	Auto-reload shadow enable 0: The shadow register for TIMERx_CAR register is disabled 1: The shadow register for TIMERx_CAR register is enabled
6:5	CAM[1:0]	Counter aligns mode selection 00: No center-aligned mode (edge-aligned mode). The direction of the counter is specified by the DIR bit. 01: Center-aligned and counting down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting down, compare interrupt flag of channels can be set. 10: Center-aligned and counting up assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Only when the counter is counting up, compare

		interrupt flag of channels can be set. 11: Center-aligned and counting up/down assert mode. The counter counts under center-aligned and channel is configured in output mode (CHxMS=00 in TIMERx_CHCTL0 register). Both when the counter is counting up and counting down, compare interrupt flag of channels can be set. After the counter is enabled, CAM[1:0] cannot be switched from 0x00 to non 0x00.
4	DIR	Direction 0: Count up 1: Count down This bit is read only when the timer is configured in center-aligned mode or encoder mode.
3	Reserved	Must be kept at reset value
2	UPS	Update source This bit is used to select the update event sources by software. 0: When enabled, any of the following events generate an update interrupt or DMA request: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: When enabled, only counter overflow/underflow generates an update interrupt or DMA request.
1	UPDIS	Update disable. This bit is used to enable or disable the update event generation. 0: update event enable. The update event is generate and the buffered registers are loaded with their preloaded values when one of the following events occurs: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: update event disable. The buffered registers keep their value, while the counter and the prescaler are reinitialized if the UG bit is set or if the slave mode controller generates a hardware reset event.
0	CEN	Counter enable 0: Counter disable 1: Counter enable The CEN bit must be set by software when timer works in external clock, pause mode and encoder mode. While in event mode, the hardware can set the CEN bit automatically.

Control register 1 (TIMERx_CTL1)

Address offset: 0x04

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									MMC[2:0]			Reserved			
									rw						

Bits	Fields	Descriptions
15:7	Reserved	Must be kept at reset value
6:4	MMC[2:0]	Master mode control These bits control the selection of TRGO signal, which is sent in master mode to slave timers for synchronization function. 000: Reset. When the UPG bit in the TIMERx_SWEVG register is set or a reset is generated by the slave mode controller, a TRGO pulse occurs. And in the latter case, the signal on TRGO is delayed compared to the actual reset. 001: Enable. This mode is useful to start several timers at the same time or to control a window in which a slave timer is enabled. In this mode the master mode controller selects the counter enable signal TIMERx_EN as TRGO. The counter enable signal is set when CEN control bit is set or the trigger input in pause mode is high. There is a delay between the trigger input in pause mode and the TRGO output, except if the master-slave mode is selected. 010: Update. In this mode the master mode controller selects the update event as TRGO. 011: Capture/compare pulse. In this mode the master mode controller generates a TRGO pulse when a capture or a compare match occurred. 100: Compare. In this mode the master mode controller selects the O0CPRE signal as TRGO 101: Compare. In this mode the master mode controller selects the O1CPRE signal as TRGO 110: Compare. In this mode the master mode controller selects the O2CPRE signal as TRGO 111: Compare. In this mode the master mode controller selects the O3CPRE signal as TRGO
3:0	Reserved	Must be kept at reset value.

Output compare mode:

Bits	Fields	Descriptions
15:7	Reserved	Must be kept at reset value.
6:4	CH0COMCTL[2:0]	Channel 0 compare output control This bit-field controls the behavior of the output reference signal O0CPRE which drives CH0_O and CH0_ON. O0CPRE is active high, while CH0_O and CH0_ON active level depends on CH0P and CH0NP bits. 000: Frozen. The O0CPRE signal keeps stable, independent of the comparison between the register TIMERx_CH0CV and the counter TIMERx_CNT. 001: Set the channel output. O0CPRE signal is forced high when the counter matches the output compare register TIMERx_CH0CV. 010: Clear the channel output. O0CPRE signal is forced low when the counter matches the output compare register TIMERx_CH0CV. 011: Toggle on match. O0CPRE toggles when the counter matches the output compare register TIMERx_CH0CV. 100: Force low. O0CPRE is forced low level. 101: Force high. O0CPRE is forced high level. 110: PWM mode0. When counting up, O0CPRE is high as long as the counter is smaller than TIMERx_CH0CV, otherwise it is low. When counting down, O0CPRE is low as long as the counter is larger than TIMERx_CH0CV, otherwise it is high. 111: PWM mode1. When counting up, O0CPRE is low as long as the counter is smaller than TIMERx_CH0CV, otherwise it is high. When counting down, O0CPRE is high as long as the counter is larger than TIMERx_CH0CV, otherwise it is low. When configured in PWM mode, the O0CPRE level changes only when the output compare mode switches from “frozen” mode to “PWM” mode or when the result of the comparison changes. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00(COMPARE MODE).
3	CH0COMSEN	Channel 0 compare output shadow enable When this bit is set, the shadow register of TIMERx_CH0CV register, which updates at each update event, will be enabled. 0: Channel 0 output compare shadow disable 1: Channel 0 output compare shadow enable The PWM mode can be used without validating the shadow register only in single pulse mode (SPM bit in TIMERx_CTL0 register is set). This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 and CH0MS bit-filed is 00.
2	CH0COMFEN	Channel 0 output compare fast enable When this bit is set, the effect of an event on the trigger in input on the capture/compare output will be accelerated if the channel is configured in PWM0 or PWM1 mode. The output channel will treat an active edge on the trigger input as a compare match, and CH0_O is set to the compare level independently from

		the result of the comparison. 0: Channel 0 output quickly compare disable. The minimum delay from an edge on the trigger input to activate CH0_O output is 5 clock cycles. 1: Channel 0 output quickly compare enable. The minimum delay from an edge on the trigger input to activate CH0_O output is 3 clock cycles.
1:0	CH0MS[1:0]	Channel 0 I/O mode selection This bit-field specifies the work mode of the channel and the input signal selection. This bit-field is writable only when the channel is not active. (CH0EN bit in TIMERx_CHCTL2 register is reset).). 00: Channel 0 is configured as output 01: Channel 0 is configured as input, IS0 is connected to CI0FE0 10: Channel 0 is configured as input, IS0 is connected to CI1FE0 11: Channel 0 is configured as input, IS0 is connected to ITS. This mode is working only if an internal trigger input is selected through TRGS bits in TIMERx_SMCFG register.

Input capture mode:

Bits	Fields	Descriptions
15:8	Reserved	Must be kept at reset value.
7:4	CH0CAPFLT[3:0]	Channel 0 input capture filter control An event counter is used in the digital filter, in which a transition on the output occurs after N input events. This bit-field specifies the frequency used to sample CI0 input signal and the length of the digital filter applied to CI0. 0000: Filter disabled, $f_{SAMP}=f_{DTS}$, N=1 0001: $f_{SAMP}=f_{TIMER\_CK}$, N=2 0010: $f_{SAMP}= f_{TIMER\_CK}$, N=4 0011: $f_{SAMP}= f_{TIMER\_CK}$, N=8 0100: $f_{SAMP}=f_{DTS}/2$, N=6 0101: $f_{SAMP}=f_{DTS}/2$, N=8 0110: $f_{SAMP}=f_{DTS}/4$, N=6 0111: $f_{SAMP}=f_{DTS}/4$, N=8 1000: $f_{SAMP}=f_{DTS}/8$, N=6 1001: $f_{SAMP}=f_{DTS}/8$, N=8 1010: $f_{SAMP}=f_{DTS}/16$, N=5 1011: $f_{SAMP}=f_{DTS}/16$, N=6 1100: $f_{SAMP}=f_{DTS}/16$, N=8 1101: $f_{SAMP}=f_{DTS}/32$, N=5 1110: $f_{SAMP}=f_{DTS}/32$, N=6 1111: $f_{SAMP}=f_{DTS}/32$, N=8
3:2	CH0CAPPSC[1:0]	Channel 0 input capture prescaler This bit-field specifies the factor of the prescaler on channel 0 input. The prescaler is reset when CH0EN bit in TIMERx_CHCTL2 register is clear.

		00: Prescaler disable, capture is done on each channel input edge 01: Capture is done every 2 channel input edges 10: Capture is done every 4 channel input edges 11: Capture is done every 8 channel input edges
1:0	CH0MS[1:0]	Channel 0 mode selection Same as output compare mode

Channel control register 2 (TIMERx_CHCTL2)

Address offset: 0x20
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												CH0NP	Reserved	CH0P	CH0EN
												rw		rw	rw

Bits	Fields	Descriptions
15:4	Reserved	Must be kept at reset value
3	CH0NP	Channel 0 complementary output polarity When channel 0 is configured in output mode, this bit specifies the complementary output signal polarity. 0: Channel 0 active high 1: Channel 0 active low When channel 0 is configured in input mode, In conjunction with CH0P, this bit is used to define the polarity of CI0. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 or 10.
2	Reserved	Must be kept at reset value
1	CH0P	Channel 0 capture/compare polarity When channel 0 is configured in output mode, this bit specifies the output signal polarity. 0: Channel 0 active high 1: Channel 0 active low When channel 0 is configured in input mode, this bit specifies the CI0 signal polarity. [CH0NP, CH0P] will select the active trigger or capture polarity for CI0FE0 or CI1FE0. [CH0NP==0, CH0P==0]: CIxFE0's rising edge is the active signal for capture or trigger operation in slave mode. And CIxFE0 will not be inverted. [CH0NP==0, CH0P==1]: CIxFE0's falling edge is the active signal for capture or

		trigger operation in slave mode. And CIxFE0 will be inverted. [CH0NP==1, CH0P==0]: Reserved. [CH0NP==1, CH0P==1]: CIxFE0's falling and rising edge are both the active signal for capture or trigger operation in slave mode. And CIxFE0 will be not inverted. This bit cannot be modified when PROT [1:0] bit-filed in TIMERx_CCHP register is 11 or 10.
0	CH0EN	Channel 0 capture/compare function enable When channel 0 is configured in input mode, setting this bit enables CH0_O signal in active state. When channel 0 is configured in output mode, setting this bit enables the capture event in channel0. 0: Channel 0 disabled 1: Channel 0 enabled

Counter register (TIMERx_CNT)

Address offset: 0x24
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CNT[15:0]	This bit-filed indicates the current counter value. Writing to this bit-filed can change the value of the counter.

Prescaler register (TIMERx_PSC)

Address offset: 0x28
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw															

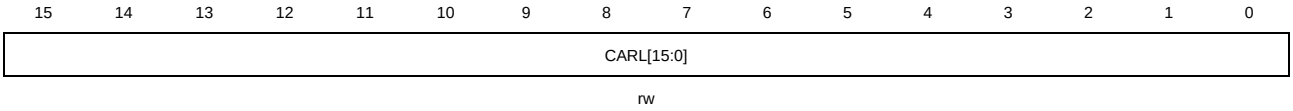
Bits	Fields	Descriptions
15:0	PSC[15:0]	Prescaler value of the counter clock The PSC clock is divided by (PSC+1) to generate the counter clock. The value of this bit-filed will be loaded to the corresponding shadow register at every update

event.

Counter auto reload register (TIMERx_CAR)

Address offset: 0x2C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

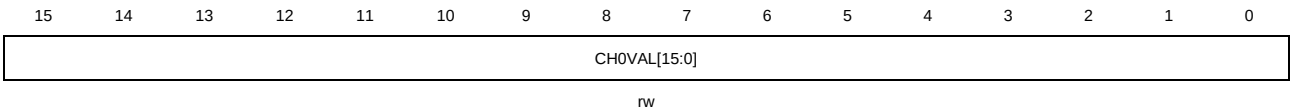


Bits	Fields	Descriptions
15:0	CARL[15:0]	Counter auto reload value This bit-filed specifies the auto reload value of the counter.

Channel 0 capture/compare value register (TIMERx_CH0CV)

Address offset: 0x34
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:0	CH0VAL[15:0]	Capture or compare value of channel0 When channel 0 is configured in input mode, this bit-filed indicates the counter value corresponding to the last capture event. And this bit-filed is read-only. When channel 0 is configured in output mode, this bit-filed contains value to be compared to the counter. When the corresponding shadow register is enabled, the shadow register updates every update event.

18.5. Basic timer (TIMERx, x=5, 6)

18.5.1. Overview

The basic timer module (Timer5, 6) reference is a 16-bit counter that can be used as an unsigned counter. The basic timer can be configured to generate DMA request and TRGO to DAC.

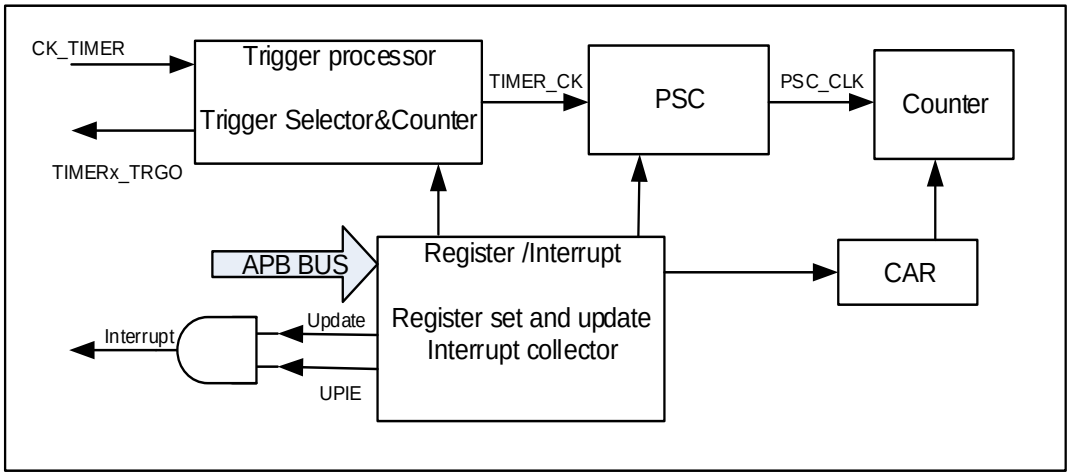
18.5.2. Characteristics

- Counter width: 16bit.
- Source of count clock is internal clock only.
- Multiple counter modes: count up.
- Programmable prescaler: 16 bit. Factor can be changed on the go.
- Single pulse mode is supported.
- Auto-reload function.
- Interrupt output or DMA request on update event.

18.5.3. Block diagram

Figure 18-76. Basic timer block diagram provides details on the internal configuration of the basic timer.

Figure 18-76. Basic timer block diagram



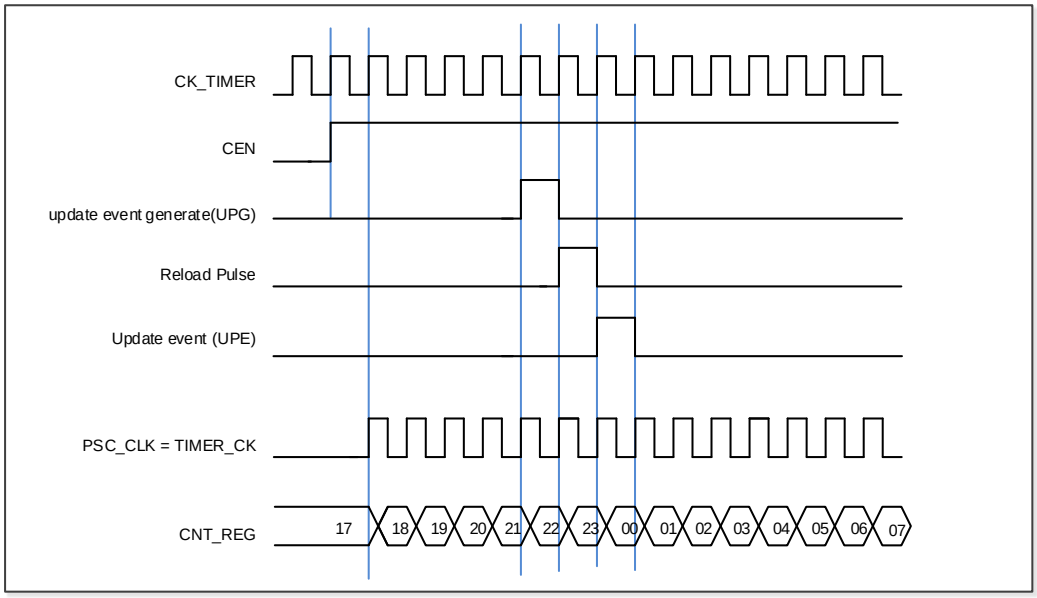
18.5.4. Function overview

Clock selection

The basic TIMER can only being clocked by the internal timer clock CK_TIMER, which is from the source named CK_TIMER in RCU

The TIMER_CK, driven counter's prescaler to count, is equal to CK_TIMER used to drive the counter prescaler. When the CEN is set, the CK_TIMER will be divided by PSC value to generate PSC_CLK.

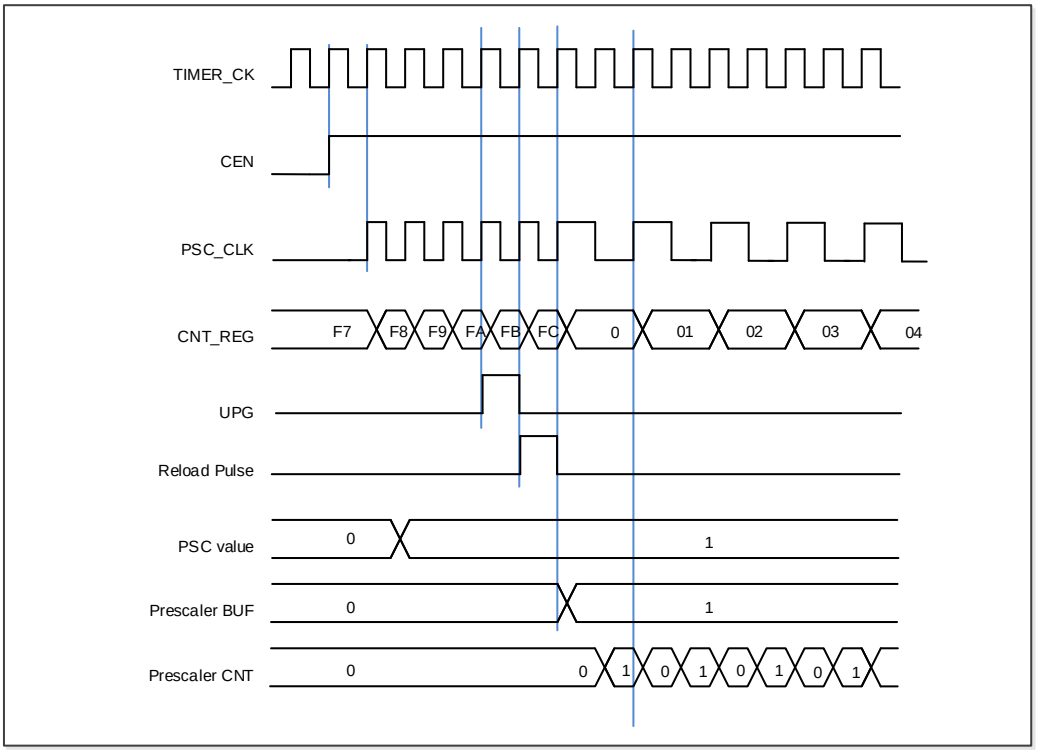
Figure 18-77. Normal mode, internal clock divided by 1



Prescaler

The prescaler can divide the timer clock (TIMER_CK) to the counter clock (PSC_CLK by any factor between 1 and 65536. It is controlled through prescaler register (TIMERx_PSC) which can be changed on the go but be taken into account at the next update event.

Figure 18-78. Counter timing diagram with prescaler division change from 1 to 2



Up counting mode

In this mode, the counter counts up continuously from 0 to the counter-reload value, which is defined in the TIMERx_CAR register, in a count-up direction. Once the counter reaches the counter reload value, the counter restarts to count once again from 0.The update event is generated at each counter overflow.

When the update event is set by the UPG bit in the TIMERx_SWEVG register, the counter value will be initialized to 0 and generates an update event.

If set the UPDIS bit in TIMERx_CTL0 register, the update event is disabled.

When an update event occurs, all the registers (repetition counter, auto reload register, prescaler register) are updated.

The following figures show some examples of the counter behavior for different clock prescaler factor when TIMERx_CAR=0x63.

Figure 18-79. Up-counter timechart, PSC=0/1

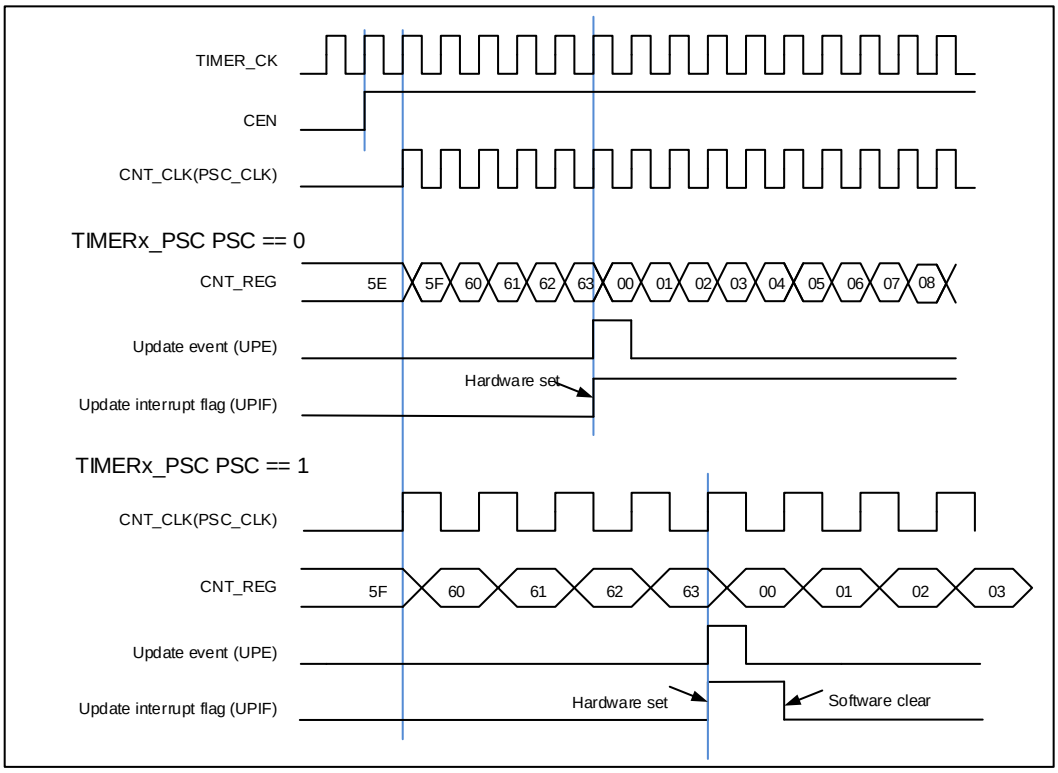


Figure 18-80. Up-counter timechart, change TIMERx_CAR on the go

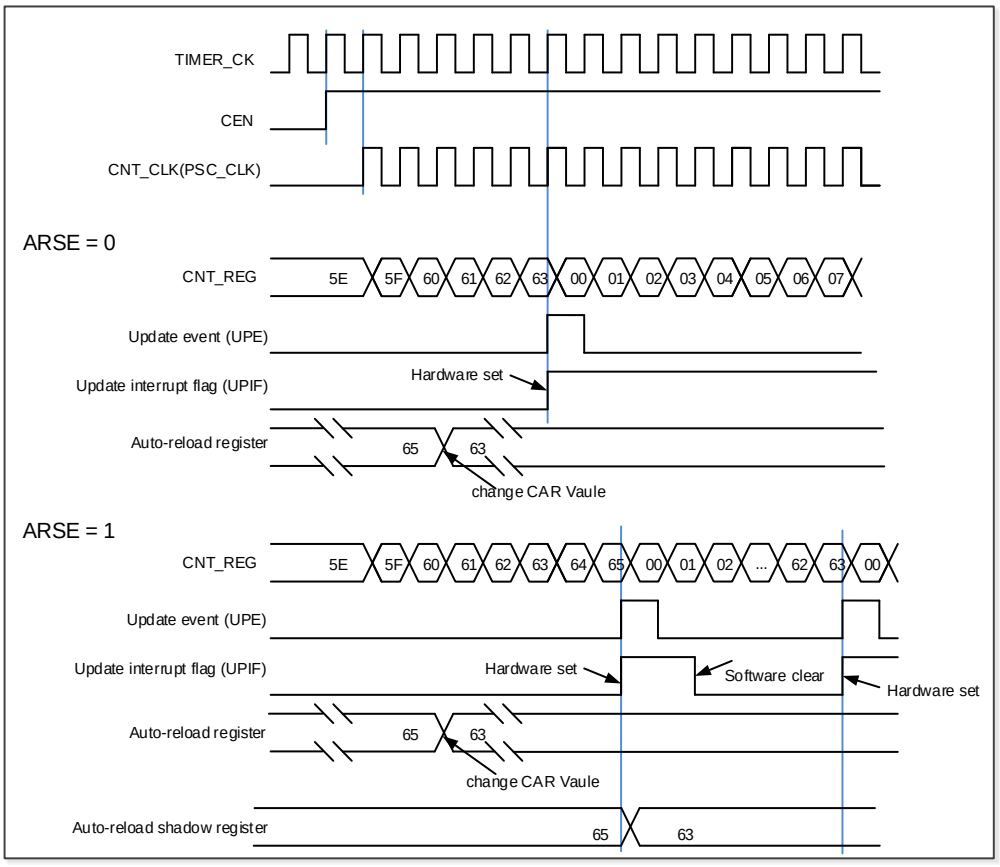


Timer debug mode

When the Cortex™-M3 halted, and the TIMERx_HOLD configuration bit in DBG_CTL2 register set to 1, the TIMERx counter stops.

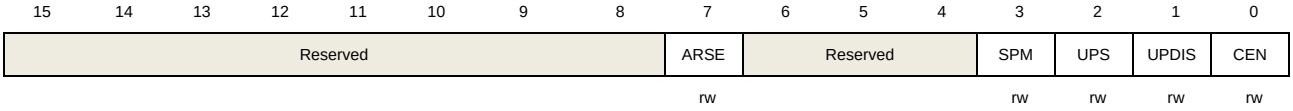
18.5.5. Register definition

TIMER5 start address: 0x4000 1000
TIMER6 start address: 0x4000 1400

Control register 0 (TIMERx_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:8	Reserved	Must be kept at reset value
7	ARSE	Auto-reload shadow enable 0: The shadow register for TIMERx_CAR register is disabled 1: The shadow register for TIMERx_CAR register is enabled
6:4	Reserved	Must be kept at reset value
3	SPM	Single pulse mode. 0: Counter continues after update event. 1: The CEN is cleared by hardware and the counter stops at next update event.
2	UPS	Update source This bit is used to select the update event sources by software. 0: When enabled, any of the following events generate an update interrupt or DMA request: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: When enabled, only counter overflow/underflow generates an update interrupt or DMA request.
1	UPDIS	Update disable. This bit is used to enable or disable the update event generation. 0: update event enable. The update event is generate and the buffered registers are loaded with their preloaded values when one of the following events occurs: – The UPG bit is set – The counter generates an overflow or underflow event – The slave mode controller generates an update event. 1: update event disable. The buffered registers keep their value, while the counter

		and the prescaler are reinitialized if the UG bit is set or if the slave mode controller generates a hardware reset event.
0	CEN	Counter enable 0: Counter disable 1: Counter enable The CEN bit must be set by software when timer works in external clock, pause mode and encoder mode. While in event mode, the hardware can set the CEN bit automatically.

Control register 1 (TIMERx_CTL1)

Address offset: 0x04
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									MMC[2:0]			Reserved			
									rw						

Bits	Fields	Descriptions
15:7	Reserved	Must be kept at reset value
6:4	MMC[2:0]	Master mode control These bits control the selection of TRGO signal, which is sent in master mode to slave timers for synchronization function. 000: Reset. When the UPG bit in the TIMERx_SWEVG register is set or a reset is generated by the slave mode controller, a TRGO pulse occurs. And in the latter case, the signal on TRGO is delayed compared to the actual reset. 001: Enable. This mode is useful to start several timers at the same time or to control a window in which a slave timer is enabled. In this mode the master mode controller selects the counter enable signal TIMERx_EN as TRGO. The counter enable signal is set when CEN control bit is set or the trigger input in pause mode is high. There is a delay between the trigger input in pause mode and the TRGO output, except if the master-slave mode is selected. 010: Update. In this mode the master mode controller selects the update event as TRGO.
3:0	Reserved	Must be kept at reset value.

Interrupt enable register (TIMERx_DMAINTEN)

Address offset: 0x0C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15:9	Reserved	Must be kept at reset value.
8	UPDEN	Update DMA request enable 0: disabled 1: enabled
7:1	Reserved	Must be kept at reset value.
0	UPIE	Update interrupt enable 0: disabled 1: enabled

Interrupt flag register (TIMERx_INTF)

Address offset: 0x10
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															UPIF
															rc_w0

Bits	Fields	Descriptions
15:1	Reserved	Must be kept at reset value.
0	UPIF	Update interrupt flag This bit is set by hardware on an update event and cleared by software. 0: No update interrupt occurred 1: Update interrupt occurred

Software event generation register (TIMERx_SWEVG)

Address offset: 0x14
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

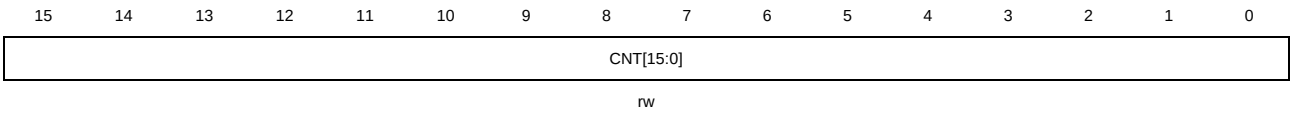
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															UPG
															w

Bits	Fields	Descriptions
15:1	Reserved	Must be kept at reset value.
0	UPG	This bit can be set by software, and cleared by hardware automatically. When this bit is set, the counter is cleared. The prescaler counter is cleared at the same time. 0: No update event occurred 1: Generate an update event

Counter register (TIMERx_CNT)

Address offset: 0x24
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

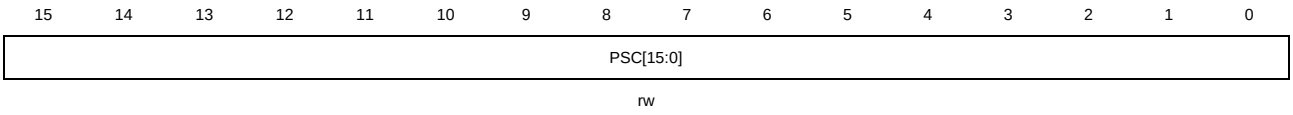


Bits	Fields	Descriptions
15:0	CNT[15:0]	This bit-filed indicates the current counter value. Writing to this bit-filed can change the value of the counter.

Prescaler register (TIMERx_PSC)

Address offset: 0x28
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:0	PSC[15:0]	Prescaler value of the counter clock The PSC clock is divided by (PSC+1) to generate the counter clock. The value of this bit-filed will be loaded to the corresponding shadow register at every update event.

Counter auto reload register (TIMERx_CAR)

Address offset: 0x2C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CARL[15:0]															
rw															

Bits	Fields	Descriptions
15:0	CARL[15:0]	Counter auto reload value This bit-filed specifies the auto reload value of the counter.

19. Universal synchronous/asynchronous receiver /transmitter (USART)

19.1. Overview

The Universal Synchronous/Asynchronous Receiver/Transmitter (USART) provides a flexible serial data exchange interface. Data frames can be transferred in full duplex or half duplex mode, synchronously or asynchronously through this interface. A programmable baud rate generator divides the peripheral clock (PCLK1 or PCLK2) to produce a dedicated baud rate lock for the USART transmitter and receiver.

Besides the standard asynchronous receiver and transmitter mode, the USART implements several other types of serial data exchange modes, such as IrDA (infrared data association) SIR mode, smartcard mode, LIN (local interconnection network) mode and half-duplex synchronous mode. It also supports multiprocessor communication mode, and hardware flow control protocol (CTS/RTS). The data frame can be transferred from LSB or MSB bit. The polarity of the data bits and the TX/RX pins can be configured flexibly.

ALL USARTs support DMA function for high-speed data communication.

19.2. Characteristics

- NRZ standard format
- Asynchronous, full duplex communication
- Programmable baud-rate generator
  - Divided from the peripheral clocks, PCLK2 for USART0/5, PCLK1 for USART1/2 and UART3/4/6/7.
  - Oversampling by 16
  - Maximum speed up to 7.5 MBits/s (PCLK2 120M and oversampling by 16)
- Fully programmable serial interface characteristics:
  - Even, odd or no-parity bit generation/detection
  - A data word length can be 8 or 9 bits
  - 0.5, 1, 1.5 or 2 stop bit generation
- Transmitter and Receiver can be enabled separately
- Hardware flow control protocol (CTS/RTS)
- DMA request for data buffer access
- LIN break generation and detection
- IrDA support

- Synchronous mode and transmitter clock output for synchronous transmission
- ISO 7816-3 compliant smartcard interface
  - Character mode (T=0)
  - Block mode (T=1)
  - Direct and inverse convention
- Multiprocessor communication
  - Enter into mute mode if address match does not occur
  - Wake up from mute mode by idle frame or address match detection
- Various status flags:
  - Flags for transfer detection: Receive buffer not empty (RBNE), Transmit buffer empty (TBE), transfer complete (TC), and busy (BSY).
  - Flags for error detection: overrun error (ORERR), noise error (NERR), frame error (FERR) and parity error (PERR)
  - Flag for hardware flow control: CTS changes (CTSF)
  - Flag for LIN mode: LIN break detected (LBDF)
  - Flag for multiprocessor communication: IDLE frame detected (IDLEF)
  - Flags for smartcard block mode: end of block (EBF) and receiver timeout (RTF)
  - Interrupt occurs at these events when the corresponding interrupt enable bits are set

While USART0/1/2/5 is fully implemented, UART3/4/6/7 is only partially implemented with the following features not supported.

- Smartcard mode
- Synchronous mode
- Hardware flow control protocol (CTS/RTS)
- Configurable data polarity

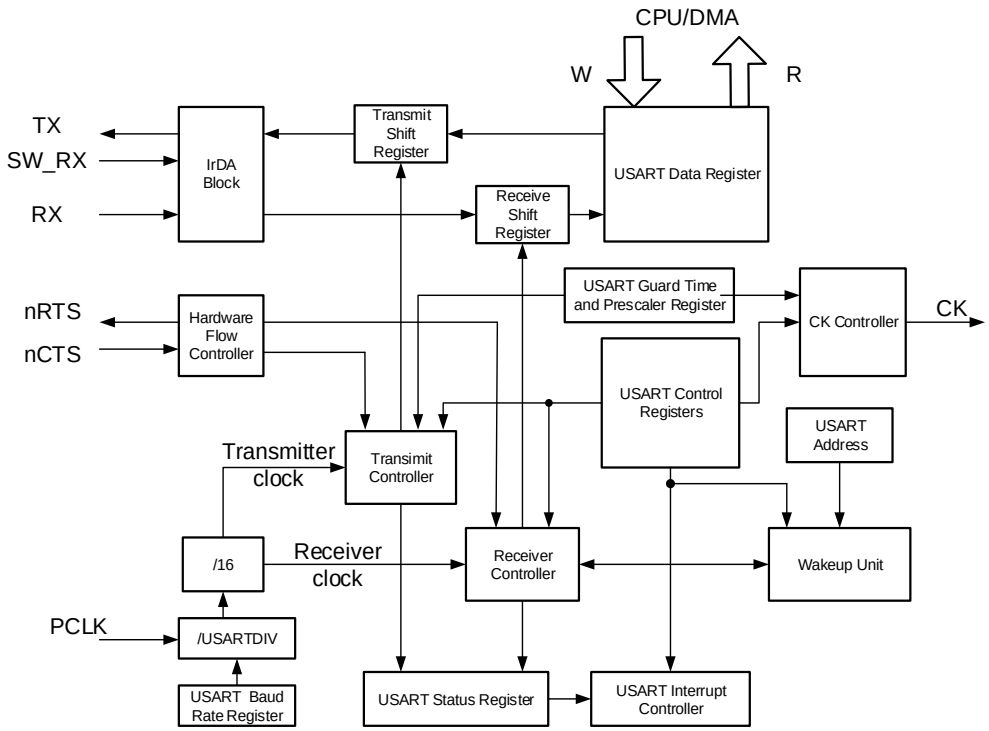
19.3. Function overview

The interface is externally connected to another device by the main pins listed as following.

Table 19-1. USART important pins description

Pin	Type	Description
RX	Input	Receive Data
TX	Output I/O (single-wire/Smartcard mode)	Transmit Data. High level when enabled but nothing to be transmitted
CK	Output	Serial clock for synchronous communication
nCTS	Input	Clear to send in hardware flow control mode
nRTS	Output	Request to send in hardware flow control mode

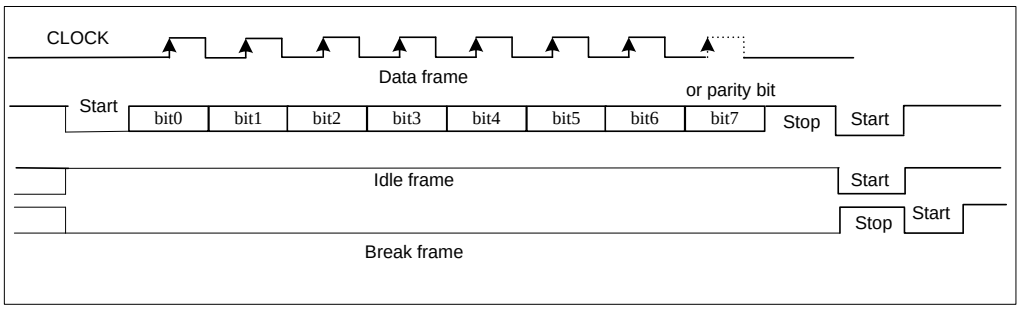
Figure 19-1. USART module block diagram



19.3.1. USART frame format

The USART frame starts with a start bit and ends up with a number of stop bits. The length of the data frame is configured by the WL bit in the USART_CTL0 register. The last data bit can be used as parity check bit by setting the PCEN bit of in USART_CTL0 register. When the WL bit is reset, the parity bit is the 7th bit. When the WL bit is set, the parity bit is the 8th bit. The method of calculating the parity bit is selected by the PM bit in USART_CTL0 register.

Figure 19-2. USART character frame (8 bits data and 1 stop bit)



In transmission and reception, the number of stop bits can be configured by the STB[1:0] bits in the USART_CTL1 register.

Table 19-2. Stop bits configuration

STB[1:0]	stop bit length (bit)	usage description
00	1	default value
01	0.5	Smartcard mode for receiving
10	2	normal USART and single-wire modes

STB[1:0]	stop bit length (bit)	usage description
11	1.5	Smartcard mode for transmitting and receiving

In an idle frame, all the frame bits are logic 1. The frame length is equal to the normal USART frame.

A break frame is configured number of low bits followed by the configured number of stop bits.The transfer speed of a USART frame depends on the frequency of the PCLK, the configuration of the baud rate generator and the oversampling mode.

19.3.2. Baud rate generation

The baud-rate divider is a 16-bit number consisting of a 12-bit integer and a 4-bit fractional part. The number formed by these two values is used by the baud rate generator to determine the bit period. Having a fractional baud-rate divider allows the USART to generate all the standard baud rates.

The baud-rate divider (USARTDIV) has the following relationship to the peripheral clock:

$$\text{USARTDIV} = \frac{\text{PCLK}}{16 \times \text{Baud Rate}} \quad (19\text{-}1)$$

The peripheral clock is PCLK2 for USART0/5 and PCLK1 for USART1/2 and UART3/4/6/7. The peripheral clock must be enabled through the clock control unit before enabling the USART.

19.3.3. USART transmitter

If the transmit enable bit (TEN) in USART_CTL0 register is set, when the transmit data buffer is not empty, the transmitter shifts out the transmit data frame through the TX pin. The polarity of the TX pin can be configured by the TINV bit in the USART_CTL3 register. Clock pulses can be output through the CK pin.

After the TEN bit is set, an idle frame will be sent. The TEN bit should not be reset while the transmission is ongoing.

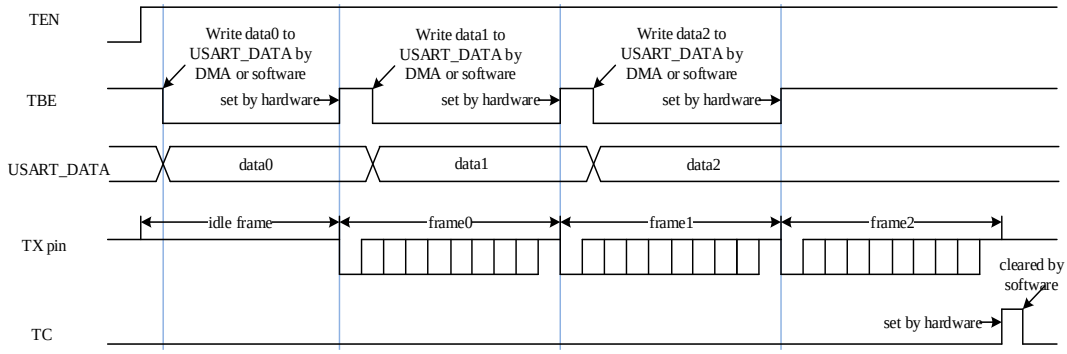
After power on, the TBE bit is high by default. Data can be written to the USART_DATA when the TBE bit of the USART_STAT0 register is asserted. The TBE bit is cleared by a writing to the USART_DATA register and will be set by hardware after the data is put into the transmit shift register. If a data is written to the USART_DATA register while a transmission is ongoing, it will be firstly stored in the transmit buffer, and transferred to the transmit shift register after the current transmission is done. If a data is written to the USART_DATA register while no transmission is ongoing, the TBE bit will be cleared and set soon, because the data will be transferred to the transmit shift register immediately.

If a frame is transmitted and the TBE bit is asserted, the TC bit of the USART_STAT0 register will be set. An interrupt is generated if the corresponding interrupt enable bit (TCIE) is set in the USART_CTL0 register.

The USART transmit procedure is shown in ***Figure 19-3. USART transmit procedure***. The software can follow this flow:

1. Set the UEN bit in USART_CTL0 to enable the USART.
2. Write the WL bit in USART_CTL0 to set the data bits length.
3. Set the STB[1:0] bits in USART_CTL1 to configure the number of stop bits.
4. Enable DMA (DENT bit) in USART_CTL2 if multibuffer communication is selected.
5. Set the baud rate in USART_BAUD.
6. Set the TEN bit in USART_CTL0.
7. Wait for the TBE being asserted.
8. Write data into the USART_DATA register.
9. Repeat step7-8 for each data, if DMA is not enabled.
10. Wait until TC=1 to finish.

Figure 19-3. USART transmit procedure



It is necessary to wait for the TC bit asserted before disabling the USART or entering the power saving mode. This bit can be cleared by a software sequence: reading the USART_STAT0 register and then writing the USART_DATA register. If the multibuffer communication is selected (DENT=1), this bit can also be cleared by writing 0 to it directly.

19.3.4. USART receiver

After power on, the USART receiver can be enabled by the following procedure:

1. Write the WL bit in USART_CTL0 to set the data bits length.
2. Set the STB[1:0] bits in USART_CTL1.
3. Enable DMA (DENR bit) in USART_CTL2 if multibuffer communication is selected.
4. Set the baud rate in USART_BAUD.
5. Set the UEN bit in USART_CTL0 to enable the USART.

6. Set the REN bit in USART_CTL0.

After being enabled, the receiver receives a bit stream after a valid start pulse has been detected. Detection on noisy error, parity error, frame error and overrun error is performed during the reception of a frame.

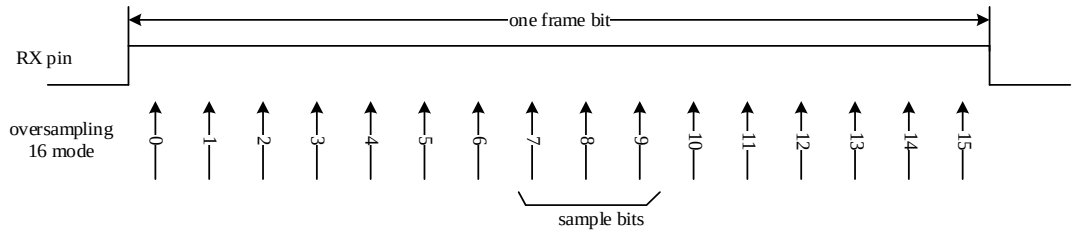
When a frame is received, the RBNE bit in USART_STAT0 is asserted, an interrupt is generated if the corresponding interrupt enable bit (RBNEIE) is set in the USART_CTL0 register. The status bits of the received are stored in the USART_STAT0 register.

The software can get the received data by reading the USART_DATA register directly, or through DMA. The RBNE status is cleared by a read operation on the USART_DATA register, whatever it is performed by software directly, or through DMA.

The REN bit should not be disabled when reception is ongoing, or the current frame will be lost.

By default, the receiver gets three samples to evaluate the value of a frame bit. While in the oversampling 16 mode, the 7th, 8th, and 9th samples are used. If two or more samples of a frame bit is 0, the frame bit is confirmed as a 0, else 1. If the three samples of any bit in a frame are not the same, whatever it is a start bit, data bit, parity bit or stop bit, a noisy error (NERR) status will be generated for the frame. An interrupt is generated, if the receive DMA is enabled and the ERRIE bit in USART_CTL2 register is set.

Figure 19-4. Oversampling method of a receive frame bit



If the parity check function is enabled by setting the PCEN bit in the USART_CTL0 register, the receiver calculates the expected parity value while receiving a frame. The received parity bit will be compared with this expected value. If they are not the same, the parity error (PERR) bit in USART_STAT0 register will be set. An interrupt is generated, if the PERRIE bit in USART_CTL0 register is set.

If the RX pin is evaluated as 0 during a stop bit, the frame error (FERR) bit in USART_STAT0 register will be set. An interrupt is generated, if the receive DMA is enabled and the ERRIE bit in USART_CTL2 register is set.

When a frame is received, if the RBNE bit is not cleared yet, the last frame will not be stored in the receive data buffer. The overrun error (ORERR) bit in USART_STAT0 register will be set. An interrupt is generated, if the receive DMA is enabled and the ERRIE bit in USART_CTL2 register is set, or if the RBNEIE is set.

The RBNE, NERR, PERR, FERR and ORERR flags of a reception are always set at the same time. If the receive DMA is not enabled, software can check NERR, PERR, FERR and ORERR

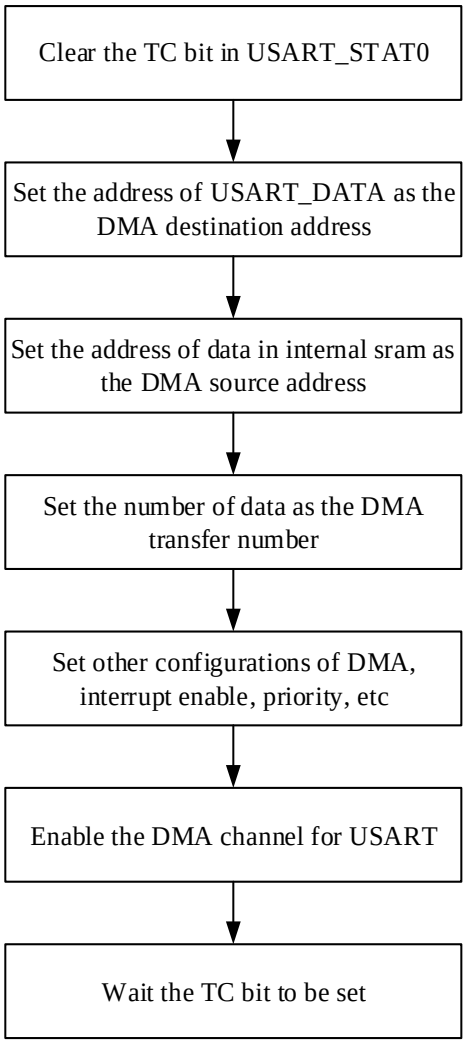
flags when serving the RBNE interrupt.

19.3.5. Use DMA for data buffer access

To reduce the burden of the processor, DMA can be used to access the transmitting and receiving data buffer. The DENT bit in USART_CTL2 is used to enable the DMA transmission, and the DENR bit in USART_CTL2 is used to enable the DMA reception.

When DMA is used for USART transmission, DMA transfers data from internal sram to the transmit data buffer of the USART. The configuration step is shown in ***Figure 19-5. Configuration step when using DMA for USART transmission***.

Figure 19-5. Configuration step when using DMA for USART transmission

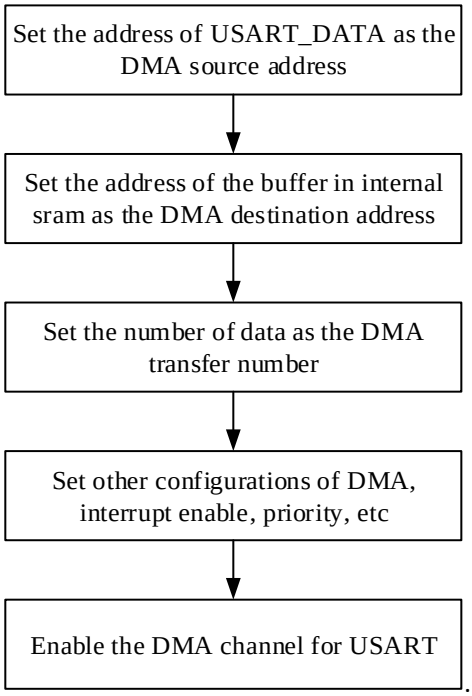


After all of the data frames are transmitted, the TC bit in USART_STAT0 is set. An interrupt occurs if the TCIE bit in USART_CTL0 is set.

When DMA is used for USART reception, DMA transfers data from the receive data buffer of the USART to the internal sram. The configuration step is shown in ***Figure 19-6. Configuration step when using DMA for USART reception***. If the ERRIE bit in USART_CTL2 is set, interrupts can be generated by the error status bits (FERR, ORERR and

NERR) in USART_STAT0.

Figure 19-6. Configuration step when using DMA for USART reception

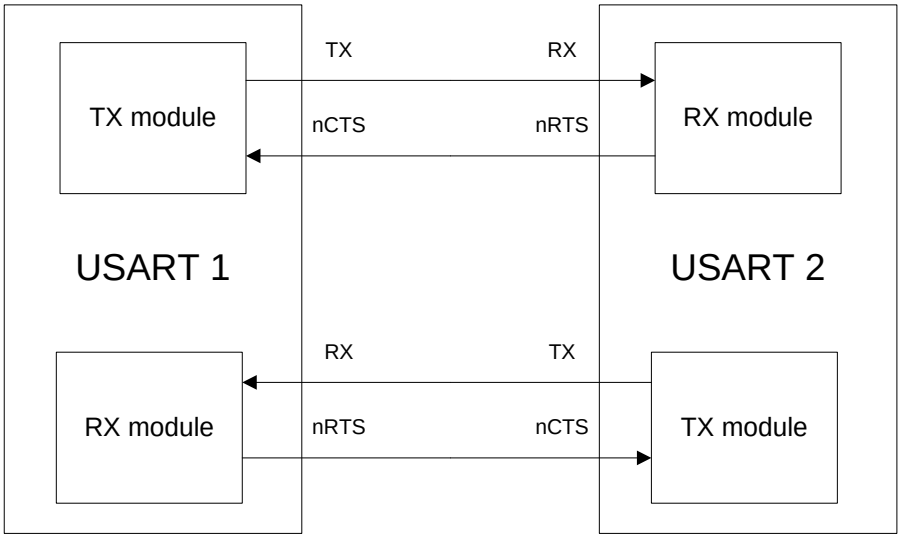


When the number of the data received by USART reaches the DMA transfer number, an end of transfer interrupt can be generated in the DMA module.

19.3.6. Hardware flow control

The hardware flow control function is realized by the nCTS and nRTS pins. The RTS flow control is enabled by writing ‘1’ to the RTSEN bit in USART_CTL2 and the CTS flow control is enabled by writing ‘1’ to the CTSEN bit in USART_CTL2.

Figure 19-7. Hardware flow control between two USARTs



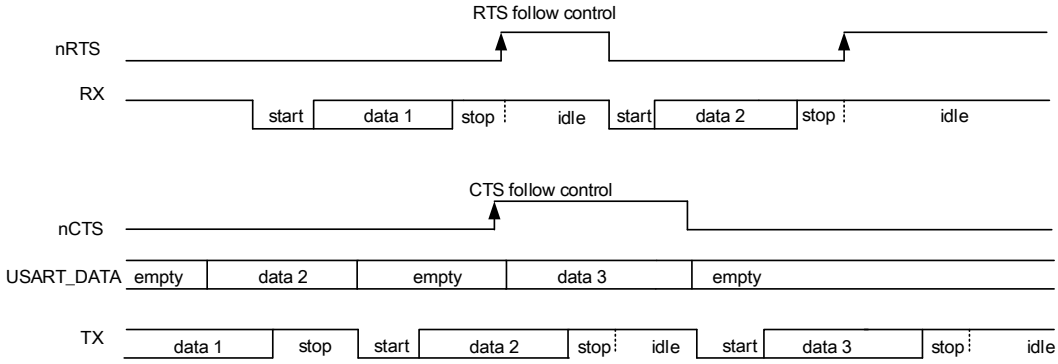
RTS flow control

The USART receiver outputs the nRTS, which reflects the status of the receive buffer. When data frame is received, the nRTS signal goes high to prevent the transmitter from sending next frame. The nRTS signal keeps high when the receive buffer is full, and can be cleared by reading the USART_DATA register.

CTS flow control

The USART transmitter monitors the nCTS input pin to decide if a data frame can be transmitted. If the TBE bit in USART_STAT0 is '0' and the nCTS signal is low, the transmitter transmits the data frame. When the nCTS signal goes high during a transmission, the transmitter stops after the current transmission is accomplished.

Figure 19-8. Hardware flow control



If the CTS flow control is enabled, the CTSF bit in USART_STAT0 is set when the nCTS pin toggles. An interrupt is generated if the CTSIE bit in USART_CTL2 is set.

19.3.7. Multi-processor communication

In multiprocessor communication, several USARTs are connected as a network. It will be a big burden for a device to monitor all of the messages on the RX pin. To reduce the burden of a device, software can put an USART module into a mute mode by setting the RWU bit in USART_CTL0 register.

If a USART is in mute mode, all of the receive status bits cannot be set. Software can wake up the USART by resetting the RWU bit.

The USART can also be wake up by hardware in one of the two methods: idle frame method and address match method.

The idle frame wake up method is selected by default. When an idle frame is detected on the RX pin, the hardware clears the RWU bit and exits the mute mode. When wake up at an idle frame, the IDLEF bit in USART_STAT0 is not set.

When the WM bit in USART_CTL0 register is set, the MSB bit of a frame is detected as the

address flag. If the address flag is high, the frame is treated as an address frame. If the address flag is low, the frame is treated as a data frame. If the LSB 4 bits of an address frame are the same as the ADDR[3:0] bits in the USART_CTL1 register, the hardware clears the RWU bit and exits the mute mode. The RBNE bit is set for the frame that wakes up the USART. The status bits are available in the USART_STAT0 register. If the LSB 4 bits of an address frame differs from the ADDR[3:0] bits in the USART_CTL1 register, the hardware sets the RWU bit and enters mute mode automatically. In this situation, the RBNE bit is not set.

If the address match method is selected, the receiver does not check the parity value of an address frame by default. If the PCEN bit in USART_CTL0 is set, the MSB bit will be checked as the parity bit, and the bit preceding the MSB bit is detected as the address flag.

19.3.8. LIN mode

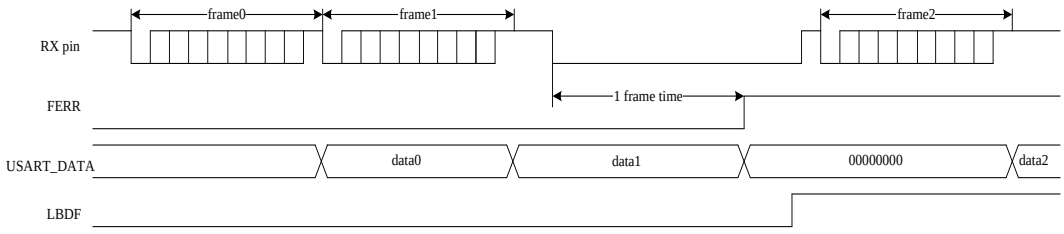
The local interconnection network mode is enabled by setting the LMEN bit in USART_CTL1. The CKEN, STB[1:0] bits in USART_CTL1 and the SCEN, HDEN, IREN bits in USART_CTL2 should be reset in LIN mode.

When transmitting a normal data frame, the transmission procedure is the same as the normal USART mode.The data bits length can only be 8. When the SBKCMD bit in USART_CTL0 is set, the USART transmits continuous 13 ‘0’ bits, following by 1 stop bit.

The break detection function is totally independent from the normal USART receiver. So a break frame can be detected during the idle state or during a frame. The expected length of a break frame can be selected by LBLEN in USART_CTL1. When the RX pin is detected at low state for a time that is equal to or longer than the expected break frame length (10 bits when LBLEN=0, or 11 bits when LBLEN=1), the LBDF in USART_STAT0 is set. An interrupt occurs if the LBDIE bit in USART_CTL1 is set.

As shown in ***Figure 19-9. Break frame occurs during idle state***, if a break frame occurs during the idle state on the RX pin, the USART receiver will receive an all ‘0’ frame, with an asserted FERR status.

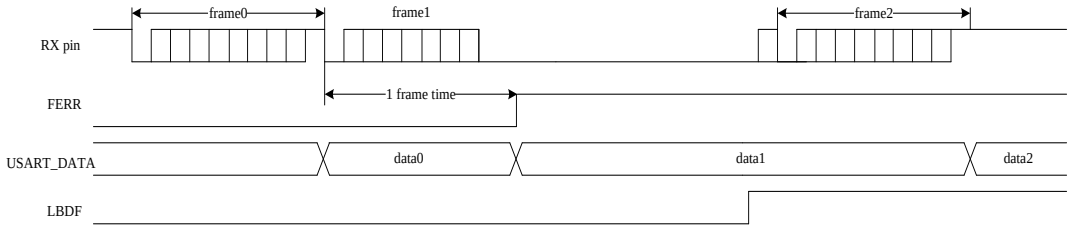
Figure 19-9. Break frame occurs during idle state



As shown in ***Figure 19-10. Break frame occurs during a frame***, if a break frame occurs

during a frame on the RX pin, the FERR status will be asserted for the current frame.

Figure 19-10. Break frame occurs during a frame



19.3.9. Synchronous mode

The USART can be used for full-duplex synchronous serial communications only in master mode, by setting the CKEN bit in USART_CTL1. The LMEN bit in USART_CTL1 and SCEN, HDEN, IREN bits in USART_CTL2 should be reset in synchronous mode. The CK pin is the synchronous USART transmitter clock output, and can be only activated when the TEN bit is enabled. No clock pulse will be sent through the CK pin during the start bit and stop bit transmission. The CLEN bit in USART_CTL1 can be used to determine whether the clock is output or not during the last (address flag) bit transmission. The CPH bit in USART_CTL1 can be used to determine whether data is captured on the first or the second clock edge. The CPL bit in USART_CTL1 can be used to configure the clock polarity in the USART synchronous idle state.

The CPL, CPH and CLEN bits in USART_CTL1 determine the waveform on the CK pin. Software can only change them when the USART is disabled (UEN=0).

If the REN bit in USART_CTL0 is set, the receiver works differently from the normal USART reception method. The receiver samples the data on the capture edge of the CK pin without any oversampling.

Figure 19-11. Example of USART in synchronous mode

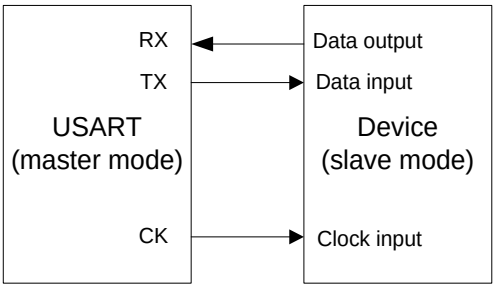


Figure 19-12. 8-bit format USART synchronous waveform (CLEN=1)

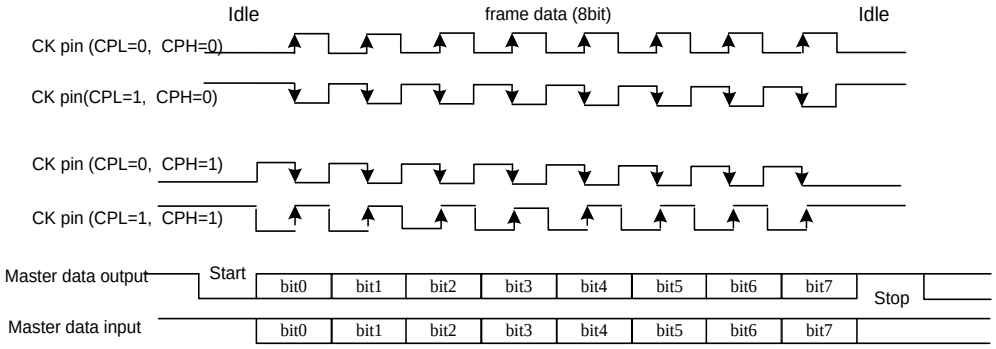
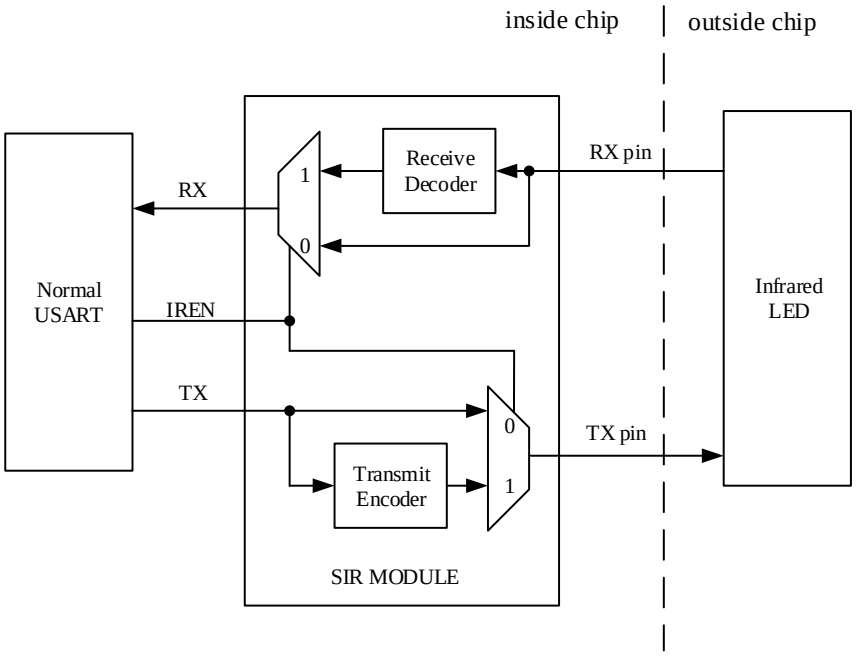


19.3.10. IrDA SIR ENDEC mode

The IrDA mode is enabled by setting the IREN bit in USART_CTL2. The LMEN, STB[1:0], CKEN bits in USART_CTL1 and HDEN, SCEN bits in USART_CTL2 should be reset in IrDA mode.

In IrDA mode, the USART transmission data frame is modulated in the SIR transmit encoder and transmitted to the infrared LED through the TX pin. The SIR receive decoder receives the modulated signal from the infrared LED through the RX pin, and puts the demodulated data frame to the USART receiver. The baud rate should not be larger than 115200 for the encoder.

Figure 19-13. IrDA SIR ENDEC module

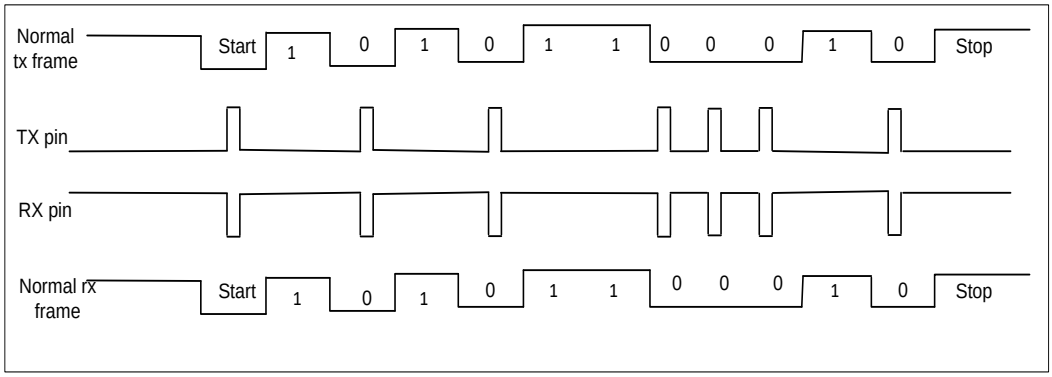


In IrDA mode, the polarity of the TX pin and RX pin is different. The TX pin is usually at low state, while the RX pin is usually at high state. The IrDA pins keep stable to represent the logic ‘1’, while an infrared light pulse on the IrDA pins (a Return to Zero signal) represents the

logic ‘0’. The pulse width should be 3/16 of a bit period. The IrDA could not detect any pulse if the pulse width is less than 1 PSC clock. While it can detect a pulse by chance if the pulse width is greater than 1 but smaller than 2 times PSC clock.

Because the IrDA is a half-duplex protocol, the transmission and the reception should not be carried out at the same time in the IrDA SIR ENDEC block.

Figure 19-14. IrDA data modulation



The SIR submodule can work in low power mode by setting the IRLP bit in USART_CTL2. The transmit encoder is driven by a low speed clock, which is divided from the PCLK. The divide ratio is configured by the PSC[7:0] bits in USART_GP register. The pulse width on the TX pin is 3 cycles of this low speed clock. The receiver decoder works in the same manner as the normal IrDA mode.

19.3.11. Half-duplex communication mode

The half-duplex communication mode is enabled by setting the HDEN bit in USART_CTL2. The LMEN, CKEN bits in USART_CTL1 and SCEN, IREN bits in USART_CTL2 should be reset in half-duplex communication mode.

In the half-duplex mode the receive line is internally connected to the TX pin, and the RX pin is no longer used. The TX pin should be configured as output open drain mode. The software should make sure the transmission and reception process never conflict each other.

19.3.12. Smartcard (ISO7816-3) mode

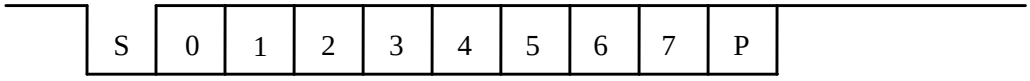
The smartcard mode is an asynchronous mode, which is designed to support the ISO7816-3 protocol. Both the character (T=0) mode and the block (T=1) mode are supported. The smartcard mode is enabled by setting the SCEN bit in USART_CTL2. The LMEN bit in USART_CTL1 and HDEN, IREN bits in USART_CTL2 should be reset in smartcard mode.

A clock is provided to the external smart card through the CK pin after the CKEN bit is set. The clock is divided from the PCLK. The divide ratio is configured by the PSC[4:0] bits in USART_GP register. The CK pin only provides a clock source to the smart card.

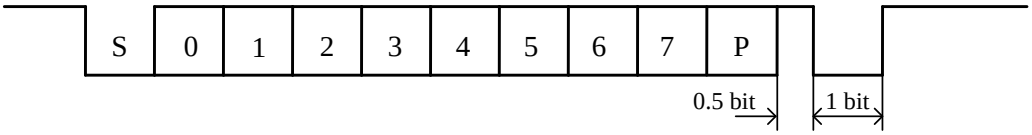
The smartcard mode is a half-duplex communication protocol. When connected to a

smartcard, the TX pin must be configured as open drain and, an external pull-up resistor will be needed, which drives a bidirectional line that is also driven by the smartcard. The data frame consists of 1 start bit, 9 data bits (1 parity bit included) and 1.5 stop bits. The 0.5 stop bit may be configured for a receiver.

Figure 19-15. ISO7816-3 frame format



ISO 7816-3 frame without parity error



ISO 7816-3 frame with parity error

Character (T=0) mode

Comparing to the time in normal operation, the transmission time from transmit shift register to the TX pin is delayed by half baud clock, and the TC flag assertion time is delayed by a guard time that is configured by the GUAT[7:0] bits in USART_GP. In Smartcard mode, the internal guard time counter starts count up after the stop bits of the last data frame, and the GUAT[7:0] bits should be configured as the character guard time (CGT) in ISO7816-3 protocol minus 12. The TC status is forced reset while the guard time counter is counting up. When the counter reaches the programmed value, TC is asserted high.

During USART transmission, if a parity error event is detected, the smartcard may NACK the current frame by pulling down the TX pin during the last 1 bit time of the stop bits. The USART can automatically resend data according to the protocol by SCRTNUM times. An interframe gap of 2.5 bits time will be inserted before the start of a resented frame. At the end of the last repeated character the TC bit is set immediately without gardtime. The USART will stop transmitting and assert the framing error status if it still receives the NACK signal after the programmed number of retries. The USART will not take the NACK signal as the start bit.

During USART reception, if the parity error is detected in the current frame, the TX pin is pulled low during the last 1 bit time of the stop bits. This signal is the NACK signal to smart card. Then a frame error occurs in smart card side. The RBNE/receive DMA request is not activated if the received character is erroneous. According to the protocol, the smart card can resend the data. The USART stops transmitting the NACK and signals the error as a parity error if the received character is still erroneous after the maximum number of retries specified in the SCRTNUM bit field. The NACK signal is enabled by setting the NKEN bit in USART_CTL2.

The idle frame and break frame are not applied for the Smartcard mode.

Block (T=1) mode

In block (T=1) mode, the NKEN bit in the USART_CTL2 register should be cleared to deactivate the NACK transmission.

When requesting a read from the smartcard, the RT[23:0] bits in USART_RT register should be programmed with the BWT (block wait time) - 11 value and RBNEIE must be set. This timeout time is expressed in baudtime units. The RTF bit in USART_STAT1 will be asserted, if no answer is received from the card before the expiration of this period. An interrupt is generated if the RTIE bit in USART_CTL3 is set. The USART generates a RBNE interrupt if the first character is received before the expiration of the RT[23:0] period. If DMA is used to read from the smartcard in block mode, the DMA must be enabled only after the first character is received.

After the first character is received, the RT[23:0] bits should be configured to the CWT (character wait time) - 11 value to enable the automatic check of the maximum interframe gap between two consecutive characters. The RTF bit in USART_STAT1 will be asserted, if the smartcard stops sending characters for the RT[23:0] period.

The USART uses a block length counter, which is reset when the USART is transmitting (TBE=0), to count the number of received characters. The length of the block, which must be programmed to the BL[7:0] bits in the USART_RT register, is received from the smartcard in the third byte of the block (prologue field). The block length counter counts up from 0 to the maximum value of BL+4. The end of the block status (EBF bit in USART_STAT1) is set after the block length counter reaches the maximum value. An interrupt is generated if the EBIE bit in USART_CTL3 is set. The RTF bit may be set in case of an error in the block length.

If DMA is used for reception, this register field must be programmed to the minimum value (0x0) before the start of the block. With this value, the end of the block interrupt occurs after the 4th received character. The block length value can be read from the receive buffer at the third byte.

If DMA is not used for reception, the BL[7:0] bits should be firstly configured with the maximum value 0xFF to avoid generating an EBF status. The real block length value can be reconfigured to the BL[7:0] bits after the third byte is received.

Direct and inverse convention

The smartcard protocol defines two conventions: direct and inverse.

When the directed convention is selected, the LSB of the data frame is transferred first, high state on the TX pin represents logic ‘1’, the parity check mode is even. In this case the MSBF and DINV bits in USART_CTL3 should be reset.

When the inverse convention is selected, the MSB of the data frame is transferred first, high state on the TX pin represents logic ‘0’, the parity check mode is even. In this case the MSBF and DINV bits in USART_CTL3 should be set.

19.3.13. USART interrupts

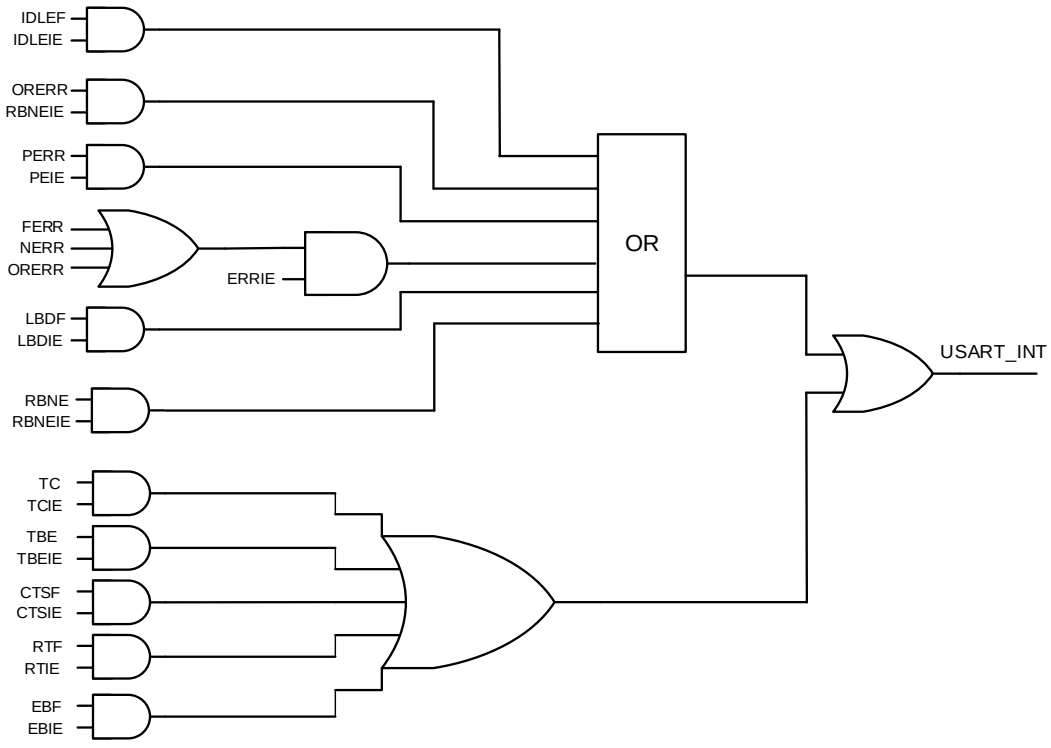
The USART interrupt events and flags are listed in the table below.

Table 19-3. USART interrupt requests

Interrupt event	Event flag	Control register	Enable Control bit
Transmit data buffer empty	TBE	USART_CTL0	TBEIE
CTS toggled flag	CTSF	USART_CTL2	CTSIE
Transmission complete	TC	USART_CTL0	TCIE
Received buff not empty	RBNE	USART_CTL0	RBNEIE
Overrun error	ORERR		
Idle frame	IDLEF	USART_CTL0	IDLEIE
Parity error	PERR	USART_CTL0	PERRIE
Break detected flag in LIN mode	LBDF	USART_CTL1	LBDIE
Receiver timeout	RTF	USART_CTL3	RTIE
End of Block	EBF	USART_CTL3	EBIE
Reception Errors (Noise flag, overrun error, framing error) in DMA reception	NERR or ORERR or FERR	USART_CTL2	ERRIE

All of the interrupt events are logically ORed together before being sent to the interrupt controller, so the USART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine.

Figure 19-16. USART interrupt mapping diagram



19.4. Register definition

USART0 start address: 0x4001 3800

USART1 start address: 0x4000 4400

USART2 start address: 0x4000 4800

USART5 start address: 0x4001 7000

UART3 start address: 0x4000 4C00

UART4 start address: 0x4000 5000

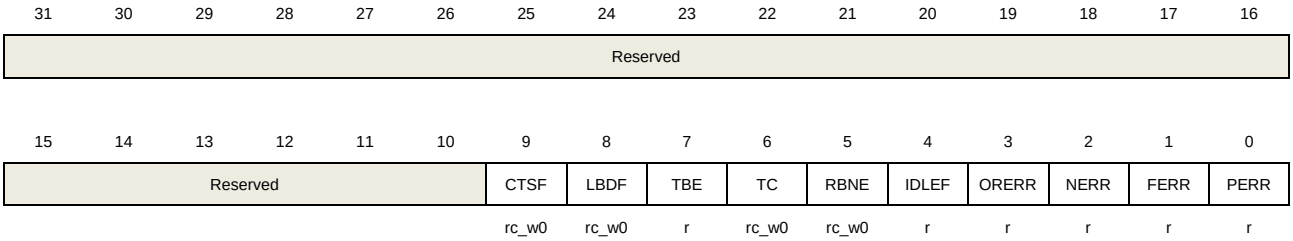
UART6 start address: 0x4000 7800

UART7 start address: 0x4000 7C00

19.4.1. Status register 0 (USART_STAT0)

Address offset: 0x00
Reset value: 0x0000 00C0

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:10	Reserved	Must be kept the reset value
9	CTSF	CTS change flag If CTSEN bit in USART_CTL2 is set, this bit is set by hardware when the nCTS input toggles. An interrupt occurs if the CTSIE bit in USART_CTL2 is set. Software can clear this bit by writing 0 to it. 0: The status of the nCTS line does not change 1: The status of the nCTS line has changed This bit is not available for UART3/4/6/7.
8	LBDF	LIN break detected flag If LMEN bit in USART_CTL1 is set, this bit is set by hardware when LIN break is detected. An interrupt occurs if the LBDIE bit in USART_CTL1 is set. Software can clear this bit by writing 0 to it.

0: The USART does not detect a LIN break
1: The USART has detected a LIN break

7	TBE	Transmit data buffer empty This bit is set after power on or when the transmit data has been transferred to the transmit shift register. An interrupt occurs if the TBEIE bit in USART_CTL0 is set. This bit is cleared when the software writes transmit data to the USART_DATA register. 0: Transmit data buffer is not empty 1: Transmit data buffer is empty
6	TC	Transmission complete This bit is set after power on. If the TBE bit has been set, this bit is set when the transmission of current data is complete. An interrupt occurs if the TCIE bit in USART_CTL0 is set. Software can clear this bit by writing 0 to it. 0: Transmission of current data is not complete 1: Transmission of current data is complete
5	RBNE	Read data buffer not empty This bit is set when the read data buffer is filled with a data frame, which has been received through the receive shift register. An interrupt occurs if the RBNEIE bit in USART_CTL0 is set. Software can clear this bit by writing 0 to it or by reading the USART_DATA register. 0: Read data buffer is empty 1: Read data buffer is not empty
4	IDLEF	IDLE frame detected flag This bit is set when the RX pin has been detected in idle state for a frame time. An interrupt occurs if the IDLEIE bit in USART_CTL0 is set. Software can clear this bit by reading the USART_STAT0 and USART_DATA registers one by one. 0: The USART module does not detect an IDLE frame 1: The USART module has detected an IDLE frame
3	ORERR	Overrun error This bit is set if the RBNE is not cleared and a new data frame is received through the receive shift register. An interrupt occurs if the ERRIE bit in USART_CTL2 is set. Software can clear this bit by reading the USART_STAT0 and USART_DATA registers one by one. 0: The USART does not detect a overrun error 1: The USART has detected a overrun error
2	NERR	Noise error flag This bit is set if the USART detects noise on the RX pin when receiving a frame. An interrupt occurs if the ERRIE bit in USART_CTL2 is set.

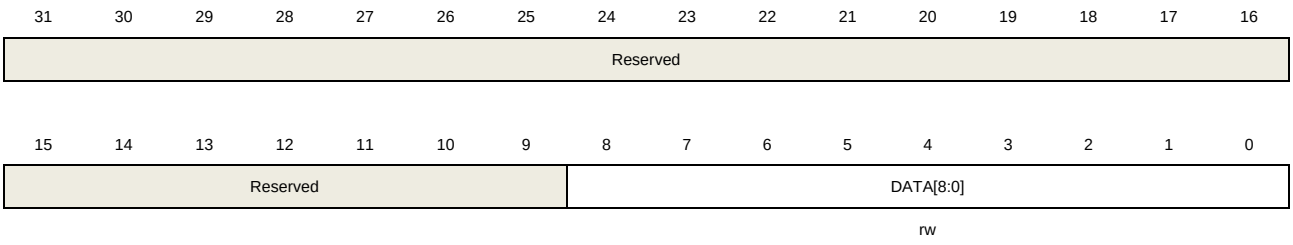
		Software can clear this bit by reading the USART_STAT0 and USART_DATA registers one by one. 0: The USART does not detect a noise error 1: The USART has detected a noise error
1	FERR	Frame error flag This bit is set when the RX pin is detected low during the stop bits of a receive frame. An interrupt occurs if the ERRIE bit in USART_CTL2 is set. Software can clear this bit by reading the USART_STAT0 and USART_DATA registers one by one. 0: The USART does not detect a frame error 1: The USART has detected a frame error
0	PERR	Parity error flag This bit is set when the parity bit of a receive frame does not match the expected parity value. An interrupt occurs if the PERRIE bit in USART_CTL0 is set. Software can clear this bit in the sequence: read the USART_STAT0 register, and then read or write the USART_DATA register. 0: The USART does not detect a parity error 1: The USART has detected a parity error

19.4.2. Data register (USART_DATA)

Offset: 0x04

Reset value: Undefined

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:9	Reserved	Must be kept the reset value
8:0	DATA[8:0]	Transmit or read data value Software can write these bits to update the transmit data or read these bits to get the receive data. If the parity check function is enabled, when transmit data is written to this register, the MSB bit (bit 7 or bit 8 depending on the WL bit in USART_CTL0) will be replaced by the parity bit.

19.4.3. Baud rate register (USART_BAUD)

Address offset: 0x08

Reset value: 0x0000 0000

The software must not write this register when the USART is enabled (UEN=1).

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31:14	Reserved	Must be kept the reset value
13	UEN	USART enable 0: USART disabled 1: USART enabled
12	WL	Word length 0: 8 Data bits 1: 9 Data bits This bit field cannot be written when the USART is enabled (UEN=1).

11	WM	Wakeup method in mute mode 0: wake up by idle frame 1: wake up by address match This bit field cannot be written when the USART is enabled (UEN=1).
10	PCEN	Parity check function enable 0: Parity check function disabled 1: Parity check function enabled This bit field cannot be written when the USART is enabled (UEN=1).
9	PM	Parity mode 0: Even parity 1: Odd parity This bit field cannot be written when the USART is enabled (UEN=1).
8	PERRIE	Parity error interrupt enable. If this bit is set, an interrupt occurs when the PERR bit in USART_STAT0 is set. 0: Parity error interrupt is disabled 1: Parity error interrupt is enabled
7	TBEIE	Transmitter buffer empty interrupt enable If this bit is set, an interrupt occurs when the TBE bit in USART_STAT0 is set. 0: Transmitter buffer empty interrupt is disabled 1: Transmitter buffer empty interrupt is enabled
6	TCIE	Transmission complete interrupt enable If this bit is set, an interrupt occurs when the TC bit in USART_STAT0 is set. 0: Transmission complete interrupt is disabled 1: Transmission complete interrupt is enabled
5	RBNEIE	Read data buffer not empty interrupt and overrun error interrupt enable If this bit is set, an interrupt occurs when the RBNE bit or the ORERR bit in USART_STAT0 is set. 0: Read data register not empty interrupt and overrun error interrupt disabled 1: Read data register not empty interrupt and overrun error interrupt enabled
4	IDLEIE	IDLE line detected interrupt enable If this bit is set, an interrupt occurs when the IDLEF bit in USART_STAT0 is set. 0: IDLE line detected interrupt disabled 1: IDLE line detected interrupt enabled
3	TEN	Transmitter enable 0: Transmitter is disabled 1: Transmitter is enabled
2	REN	Receiver enable 0: Receiver is disabled 1: Receiver is enabled

1	RWU	Receiver wakeup from mute mode. Software can set this bit to make the USART work in mute mode and reset this bit to wake up the USART. In wake up by idle frame mode (WM=0), this bit can be reset by hardware when an idle frame has been detected. In wake up by address match mode (WM=1), this bit can be reset by hardware when the USART receives an address match frame or set by hardware when the USART receives an address mismatch frame. 0: Receiver in active mode 1: Receiver in mute mode
0	SBKCMD	Send break command Software can set this bit to send a break frame. Hardware resets this bit automatically when the break frame has been transmitted. 0: Do not transmit a break frame 1: Transmit a break frame

19.4.5. Control register 1 (USART_CTL1)

Address offset: 0x10

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		1: Smartcard Mode enabled This bit field cannot be written when the USART is enabled (UEN=1). This bit is reserved for UART3/4/6/7.
4	NKEN	NACK enable in Smartcard mode This bit enables the NACK transmission when parity error occurs in smartcard mode. 0: Disable NACK transmission 1: Enable NACK transmission This bit field cannot be written when the USART is enabled (UEN=1). This bit is reserved for UART3/4/6/7.
3	HDEN	Half-duplex enable This bit enables the half-duplex USART mode. 0: Half duplex mode is disabled 1: Half duplex mode is enabled This bit field cannot be written when the USART is enabled (UEN=1).
2	IRLP	IrDA low-power This bit selects low-power mode of IrDA mode. 0: Normal mode 1: Low-power mode This bit field cannot be written when the USART is enabled (UEN=1).
1	IREN	IrDA mode enable This bit enables the IrDA mode of USART. 0: IrDA disabled 1: IrDA enabled This bit field cannot be written when the USART is enabled (UEN=1).
0	ERRIE	Error interrupt enable When DMA request for reception is enabled (DENR=1), if this bit is set, an interrupt occurs when any one of the FERR, ORERR and NERR bits in USART_STAT0 is set. 0: Error interrupt disabled 1: Error interrupt enabled

19.4.7. Guard time and prescaler register (USART_GP)

Address offset: 0x18
Reset value: 0x0000 0000

This bit field cannot be written when the USART is enabled (UEN=1).
This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GUAT[7:0]								PSC[7:0]							
rw								rw							

Bits	Fields	Descriptions
31:16	Reserved	Must be kept the reset value
15:8	GUAT[7:0]	Guard time value in Smartcard mode TC flag assertion time is delayed by GUAT[7:0] baud clock cycles. This bit field cannot be written when the USART is enabled (UEN=1). These bits are not available for UART3/4/6/7.
7:0	PSC[7:0]	When the USART IrDA low-power mode is enabled, these bits specify the division factor that is used to divide the peripheral clock (PCLK1/PCLK2) to generate the low-power frequency. 00000000: Reserved - never program this value 00000001: divides by 1 00000010: divides by 2 ... 11111111: divides by 255 When the USART works in IrDA normal mode, these bits must be set to 00000001. When the USART smartcard mode is enabled, the PSC [4:0] bits specify the division factor that is used to divide the peripheral clock (APB1/APB2) to generate the smartcard clock (CK). The actual division factor is twice as the PSC [4:0] value. 00000: Reserved - never program this value 00001: divides by 2 00010: divides by 4 ... 11111: divides by 62 The PSC [7:5] bits are reserved in smartcard mode. This bit field cannot be written when the USART is enabled (UEN=1).

19.4.8. Control register 3 (USART_CTL3)

Address offset: 0x80

Reset value: 0x0000 0000

This register is not available for UART3/4/6/7.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reserved	MSBF	DINV	TINV	RINV	Reserved	EBIE	RTIE	SCRTNUM[2:0]	RTEN
	rw	rw	rw	rw		rw	rw	rw	rw

Bits	Fields	Descriptions
31:12	Reserved	Must be kept the reset value
11	MSBF	Most significant bit first This bit specifies the sequence of the data bits in transmission and reception. 0: data is transmitted/received with the LSB first 1: data is transmitted/received with the MSB first This bit field cannot be written when the USART is enabled (UEN=1).
10	DINV	Data bit level inversion This bit specifies the polarity of the data bits in transmission and reception. 0: Data bit signal values are not inverted 1: Data bit signal values are inverted This bit field cannot be written when the USART is enabled (UEN=1).
9	TINV	TX pin level inversion This bit specifies the polarity of the TX pin. 0: TX pin signal values are not inverted 1: TX pin signal values are inverted This bit field cannot be written when the USART is enabled (UEN=1).
8	RINV	RX pin level inversion This bit specifies the polarity of the RX pin. 0: RX pin signal values are not inverted 1: RX pin signal values are inverted This bit field cannot be written when the USART is enabled (UEN=1).
7:6	Reserved	Must be kept the reset value
5	EBIE	Interrupt enable bit of end of block event If this bit is set, an interrupt occurs when the EBF bit in USART_STAT1 is set. 0: End of block interrupt is enabled 1: End of block interrupt is disabled
4	RTIE	Interrupt enable bit of receive timeout event If this bit is set, an interrupt occurs when the RTF bit in USART_STAT1 is set. 0: Receive timeout interrupt is enabled 1: Receive timeout interrupt is disabled
3:1	SCRTNUM[2:0]	Smartcard auto-retry number In Smartcard mode, these bits specify the number of retries in transmission and reception. In transmission mode, a frame can be retransmitted by SCRTNUM times. If the frame is NACKed by (SCRTNUM+1) times, the FERR is set. In reception mode, a frame reception can be tried by (SCRTNUM+1) times. If the

		parity bit mismatch event occurs (SCRTNUM+1) times for a frame, the RBNE and PERR bits are set. When these bits are configured as 0x0, there will be no automatic retransmission in transmit mode.
0	RTEN	Receiver timeout enable This bit enables the receive timeout counter of the USART. 0: Receiver timeout function disabled 1: Receiver timeout function enabled

19.4.9. Receiver timeout register (USART_RT)

Address offset: 0x84
Reset value: 0x0000 0000
This register is not available for UART3/4/6/7.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BL[7:0]								RT[23:16]							
rw								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RT[15:0]															
rw															

Bits	Fields	Descriptions
31:24	BL[7:0]	Block Length These bits specify the block length in Smartcard T=1 reception. Its value equals to the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1. This value, which must be programmed only once per received block, can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). The block length counter is reset when TBE=0 in Smartcard mode. In other modes, when REN=0 (receiver disabled), or when the EBF bit of USART_STAT1 is written to 0, the block length counter is reset.

23:0	RT[23:0]	Receiver timeout threshold These bits are used to specify receiver timeout value in terms of number of baud clocks. If Smartcard mode is not enabled, the RTF bit of USART_STAT1 is set if no new start bit is detected longer than RT bits time after the last received character. If Smartcard mode is enabled, the CWT and BWT are implemented by this value. In this case, the timeout measurement is started from the start bit of the last received character. These bits can be written on the fly. The RTF flag will be set if the new value is lower than or equal to the internal timeout counter. These bits must only be programmed once per received character.

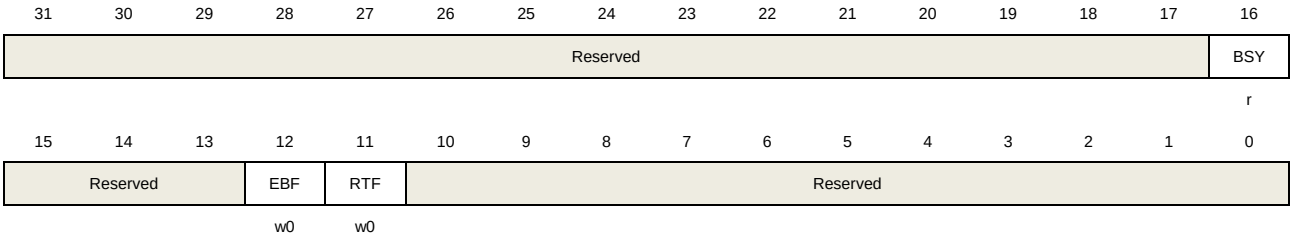
19.4.10. Status register 1 (USART_STAT1)

Address offset: 0x88

Reset value: 0x0000 0000

This register is not available for UART3/4/6/7.

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:17	Reserved	Must be kept the reset value
16	BSY	Busy flag This bit is set when the USART is receiving a data frame. 0: USART reception path is idle 1: USART reception path is working
15:13	Reserved	Must be kept the reset value
12	EBF	End of block flag This bit is set when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4. An interrupt occurs if the EBIE bit in USART_CTL3 is set. Software can clear this bit by writing 0 to it. 0: End of block event not occurs 1: End of block event has occurred
11	RTF	Receiver timeout flag

		This bit is set when the RX pin is in idle state for longer than RT bits time. An interrupt occurs if the RTIE bit in USART_CTL3 is set. Software can clear this bit by writing 0 to it. 0: Receiver timeout event does not occur 1: Receiver timeout event has occurred
10:0	Reserved	Must be kept the reset value

20. Inter-integrated circuit interface (I2C)

20.1. Overview

The I2C (inter-integrated circuit) module provides an I2C interface which is an industry standard two-line serial interface for MCU to communicate with external I2C interface. I2C bus uses two serial lines: a serial data line, SDA, and a serial clock line, SCL.

The I2C interface implements standard I2C protocol with standard-mode and fast-mode as well as CRC calculation and checking, SMBus (system management bus) and PMBus (power management bus). It also supports multi-master I2C bus. The I2C interface provides DMA mode for users to reduce CPU overload.

20.2. Characteristics

- Parallel-bus to I2C-bus protocol converter and interface
- Both master and slave functions with the same interface
- Bi-directional data transfer between master and slave
- Supports 7-bit and 10-bit addressing and general call addressing
- Multi-master capability
- Supports standard-mode (up to 100 kHz) and fast-mode (up to 400 kHz)
- Configurable SCL stretching in slave mode
- Supports DMA mode
- SMBus 2.0 and PMBus compatible
- 2 Interrupts: one for successful byte transmission and the other for error event
- Optional PEC (packet error checking) generation and check

20.3. Function overview

Figure 20-1. I2C module block diagram below provides details on the internal configuration of the I2C interface.

Figure 20-1. I2C module block diagram

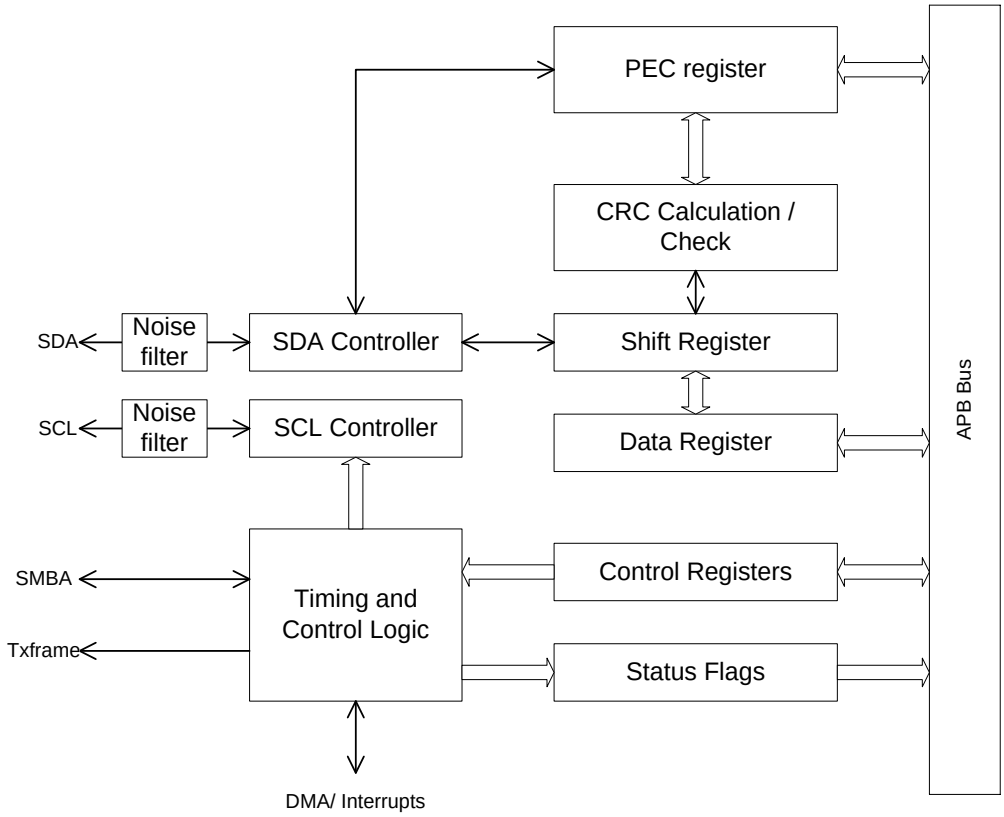


Table 20-1. Definition of I2C-bus terminology (refre to the I2C specification of philips semiconductors)

Term	Description
Transmitter	the device which sends data to the bus
Receiver	the device which receives data from the bus
Master	the device which initiates a transfer, generates clock signals and terminates a transfer
Slave	the device addressed by a master
Multi-master	more than one master can attempt to control the bus at the same time without corrupting the message
Synchronization	procedure to synchronize the clock signals of two or more devices
Arbitration	procedure to ensure that, if more than one master tries to control the bus simultaneously, only one is allowed to do so and the winning master's message is not corrupted

20.3.1. SDA and SCL lines

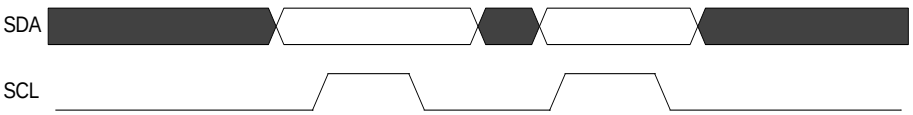
The I2C module has two external lines, the serial data SDA and serial clock SCL lines. The two wires carry information between the devices which connected to the bus.

Both SDA and SCL are bidirectional lines, they are connected to a positive supply voltage via current-source or pull-up resistor. When the bus is free, both lines are HIGH. The output stages of devices connected to the bus must have an open-drain or open-collect to perform the wired-AND function. Data on the I2C-bus can be transferred at rates of up to 100 kbit/s in the standard-mode and up to 400 kbit/s in the fast-mode. Due to the variety of different technology devices (CMOS, NMOS, bipolar) that can be connected to the I2C-bus, the voltage levels of the logical '0' (LOW) and '1' (HIGH) are not fixed and depend on the associated level of V_{DD}.

20.3.2. Data validation

The data on the SDA line must be stable during the HIGH period of the clock. The HIGH or LOW state of the data line can only change when the clock signal on the SCL line is LOW (see ***Figure 20-2. Data validation***). One clock pulse is generated for each data bit transferred.

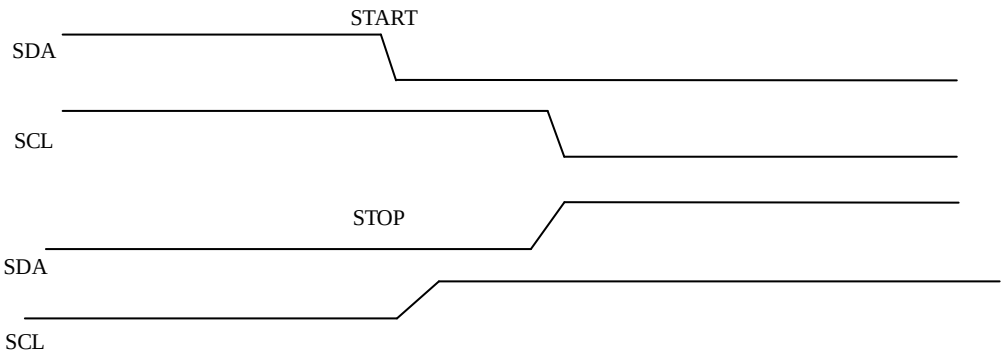
Figure 20-2. Data validation



20.3.3. START and STOP condition

All transactions begin with a START (S) and are terminated by a STOP (P) (see ***Figure 20-3. START and STOP condition***).A HIGH to LOW transition on the SDA line while SCL is HIGH defines a START condition. A LOW to HIGH transition on the SDA line while SCL is HIGH defines a STOP condition.

Figure 20-3. START and STOP condition



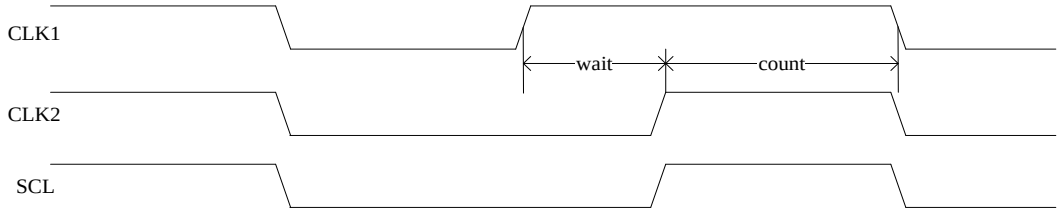
20.3.4. Clock synchronization

Two masters can begin transmitting on a free bus at the same time and there must be a

method for deciding which master takes control of the bus and complete its transmission. This is done by clock synchronization and bus arbitration. In a single master system, clock synchronization and bus arbitration are unnecessary.

Clock synchronization is performed using the wired-AND connection of I2C interfaces to the SCL line. This means that a HIGH to LOW transition on the SCL line causes the masters concerned to start counting off their LOW period and, once a master clock has gone LOW, it holds the SCL line in that state until the clock HIGH state is reached (see ***Figure 20-4. Clock synchronization***). However, if another clock is still within its LOW period, the LOW to HIGH transition of this clock may not change the state of the SCL line. The SCL line is therefore held LOW by the master with the longest LOW period. Masters with shorter LOW periods enter a HIGH wait-state during this time.

Figure 20-4. Clock synchronization



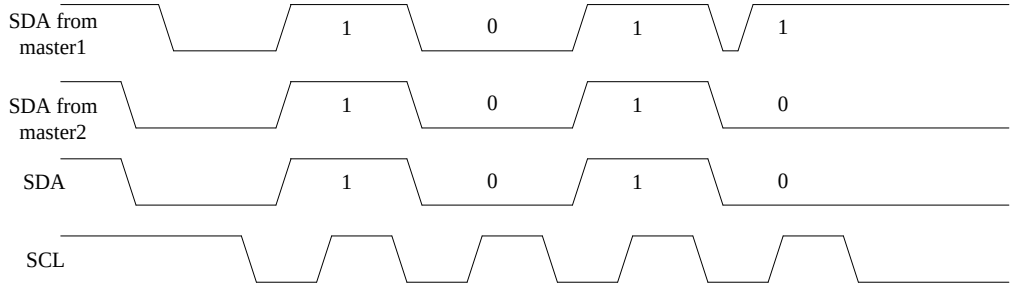
20.3.5. Arbitration

Arbitration, like synchronization, is part of the protocol where more than one master is used in the system. Slaves are not involved in the arbitration procedure.

A master may start a transfer only if the bus is free. Two masters may generate a START condition within the minimum hold time of the START condition which results in a valid START condition on the bus. Arbitration is then required to determine which master will complete its transmission.

Arbitration proceeds bit by bit. During every bit, while SCL is HIGH, each master checks to see whether the SDA level matches what it has sent. This process may take many bits. Two masters can complete an entire transaction without error, as long as the transmissions are identical. The first time a master tries to send a HIGH, but detects that the SDA level is LOW, then the master knows that it has lost the arbitration and turns off its SDA output driver. The other master goes on to complete its transaction.

Figure 20-5. SDA Line arbitration



20.3.6. I2C communication flow

Each I2C device is recognized by a unique address (whether it is a microcontroller, LCD driver, memory or keyboard interface) and can operate as either a transmitter or receiver, depending on the function of the device.

An I2C slave will continue to detect addresses after a START condition on I2C bus and compare the detected address with its slave address which is programmable by software. Once the two addresses match, the I2C slave will send an ACK to the I2C bus and response to the following command on I2C bus: transmitting or receiving the desired data. Additionally, if General Call is enabled by software, the I2C slave always responses to a General Call Address (0x00). The I2C block supports both 7-bit and 10-bit address modes.

An I2C master always initiates or ends a transfer using START or STOP condition and it's also responsible for SCL clock generation.

Figure 20-6. I2C communication flow with 7-bit address

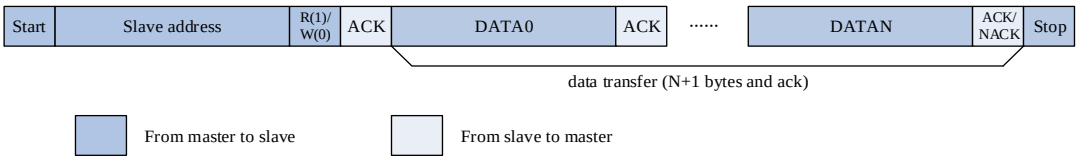


Figure 20-7. I2C communication flow with 10-bit address (Master Transmit)

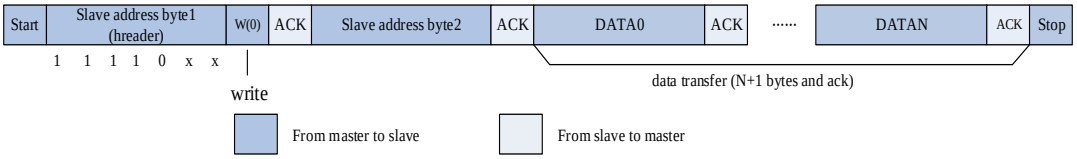

Figure 20-8. I2C communication flow with 10-bit address (Master Receive)

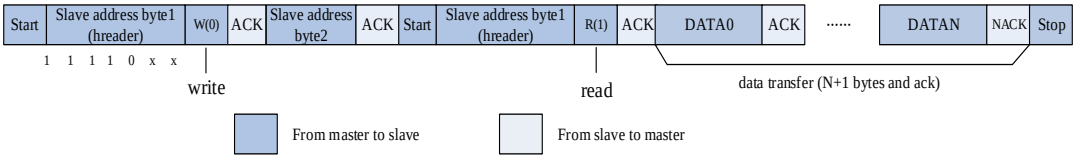


20.3.7. Programming model

An I2C device such as LCD driver may only be a receiver, whereas a memory can both receive and transmit data. In addition to transmitters and receivers, devices can also be considered as masters or slaves when performing data transfers. A master is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time,any device addressed is considered a slave.

An I2C device is able to transmit or receive data whether it's a master or a slave, thus, there're 4 operation modes for an I2C device:

- Master Transmitter
- Master Receiver

- Slave Transmitter
- Slave Receiver

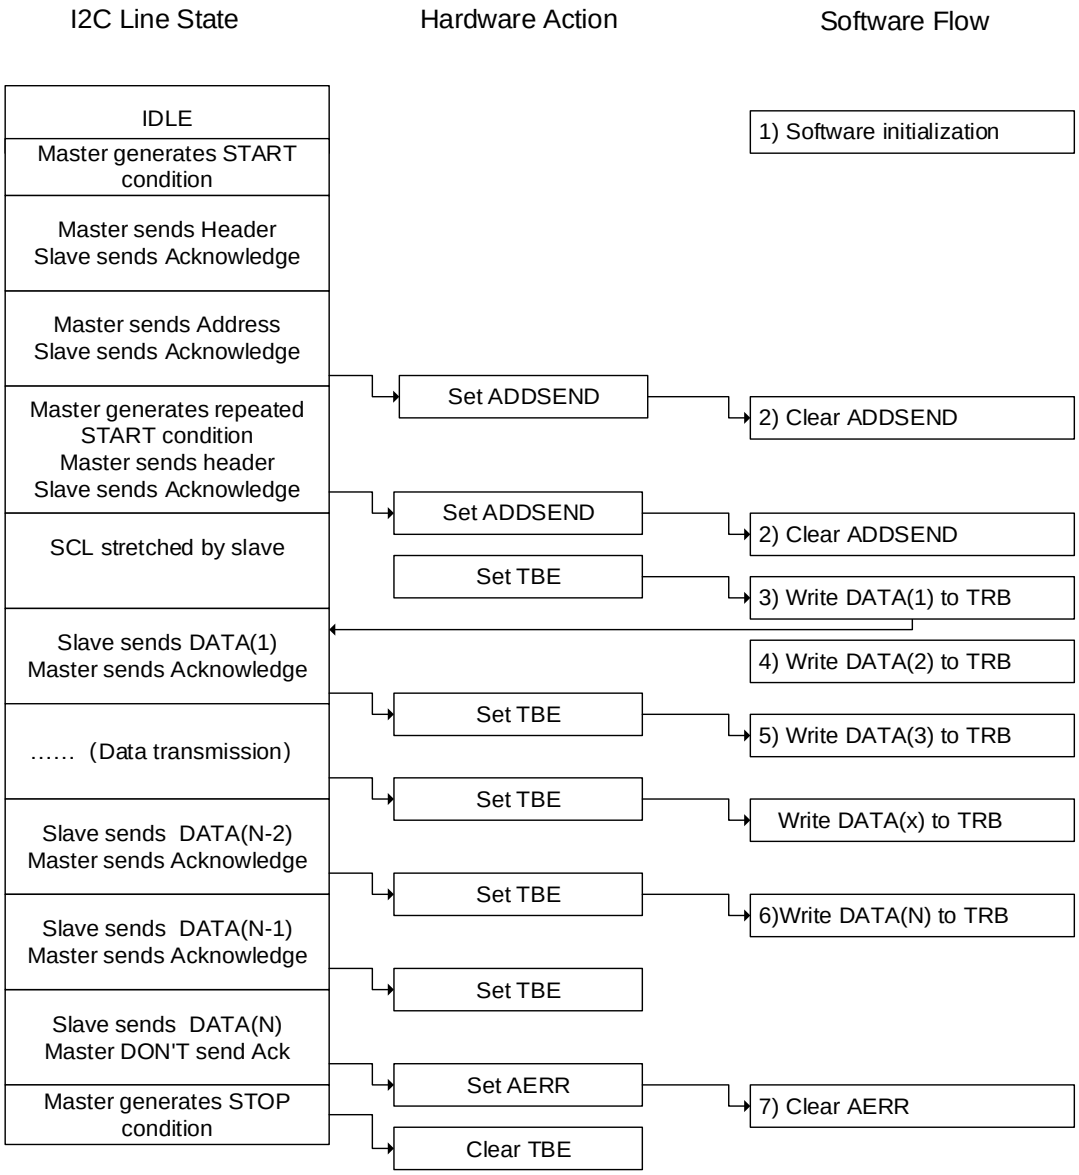
I2C block supports all of the four I2C modes. After system reset, it works in slave mode. If it's programmed by software and finished sending a START condition on I2C bus, it changes into master mode. The I2C changes back to slave mode after it's programmed by software and finished sending a STOP condition on I2C bus.

Programming model in slave transmitting mode

As is shown in ***Figure 20-9. Programming model for slave transmitting***, the following software procedure should be followed if users wish to make transaction in slave transmitter mode:

1. First of all, software should enable I2C peripheral clock as well as configure clock related registers in I2C_CTL1 to make sure correct I2C timing. After enabled and configured, I2C operates in its default slave state and waits for START condition followed by address on I2C bus.
2. After receiving a START condition followed by a matched address, either in 7-bit format or in 10-bit format, the I2C hardware sets the ADDSEND bit in I2C_STAT0 register, which should be monitored by software either by polling or interrupt. After that software should read I2C_STAT0 and then I2C_STAT1 to clear ADDSEND bit. If 10-bit addressing format is selected, the I2C master should then send a repeated START(Sr) condition followed by a header to the I2C bus. The slave sets ADDSEND bit again after it detects the repeated START(Sr) condition and the following header. Software needs to clear the ADDSEND bit again by reading I2C_STAT0 and then I2C_STAT1.
3. Now I2C enters data transmission stage and hardware sets TBE bit because both the shift register and data register I2C_DATA are empty. Once TBE is set, Software should write the first byte of data to I2C_DATA register, TBE is not cleared in this case because the write byte in I2C_DATA is moved to the internal shift register immediately. I2C begins to transmit data to I2C bus as soon as the shift register is not empty.
4. During the first byte's transmission, software can write the second byte to I2C_DATA, at which time the TBE bit is cleared 0, because neither I2C_DATA nor shift register is empty.
5. Any time TBE is set, software can write a byte to I2C_DATA as long as there are still data to be transmitted.
6. During the last second byte's transmission, software write the last data to I2C_DATA to clear the TBE flag and doesn't care TBE anymore. So TBE will be set after the byte's transmission and not cleared until a STOP condition.
7. I2C master doesn't acknowledge to the last byte according to the I2C protocol, so after sending the last byte, I2C slave will wait for the STOP condition on I2C bus and sets AERR (Acknowledge Error) bit to notify software that transmission completes. Software clears AERR bit by writing 0 to it.

Figure 20-9. Programming model for slave transmitting



Programming model in slave receiving mode

As is shown in ***Figure 20-10. Programming model for slave receiving***, the following software procedure should be followed if users wish to make reception in slave receiver mode:

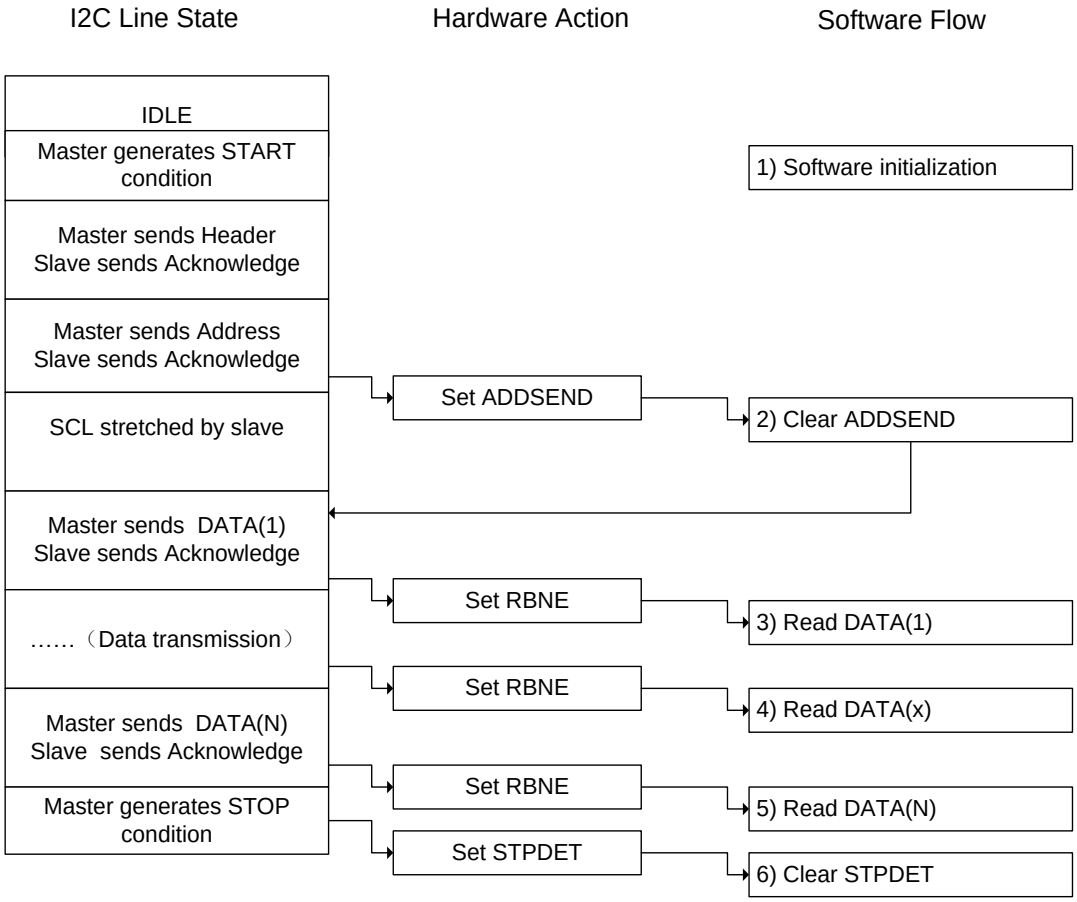
1. First of all, software should enable I2C peripheral clock as well as configure clock related registers in I2C_CTL1 to make sure correct I2C timing. After enabled and configured, I2C operates in its default slave state and waits for START condition followed by address on I2C bus.

2. After receiving a START condition followed by a matched 7-bit or 10-bit address, the I2C hardware sets the ADDSEND bit in I2C status register, which should be monitored by software either by polling or interrupt. After that software should read I2C_STAT0 and then I2C_STAT1 to clear ADDSEND bit. The I2C begins to receive data to I2C bus as

soon as ADDSEND bit is cleared.

3. As soon as the first byte is received, RBNE is set by hardware. Software can now read the first byte from I2C_DATA and RBNE is cleared as well.
4. Any time RBNE is set, software can read a byte from I2C_DATA.
5. After last byte is received, RBNE is set. Software reads the last byte.
6. STPDET bit is set when I2C detects a STOP condition on I2C bus and software reads I2C_STAT0 and then write I2C_CTL0 to clear the STPDET bit.

Figure 20-10. Programming model for slave receiving



Programming model in master transmitting mode

As it shows in ***Figure 20-11. Programming model for master transmitting***, the following software procedure should be followed if users wish to make transaction in master transmitter mode:

1. First of all, software should enable I2C peripheral clock as well as configure clock related registers in I2C_CTL1 to make sure correct I2C timing. After enabled and configured, I2C operates in its default slave state and waits for START condition followed by address on I2C bus.
2. Software set START bit requesting I2C to generate a START condition to I2C bus.

3. After sending a START condition, the I2C hardware sets the SBSEND bit in I2C status register and enters master mode. Now software should clear the SBSEND bit by reading I2C_STAT0 and then writing a 7-bit address or header of a 10-bit address to I2C_DATA. I2C begins to send address or header to I2C bus as soon as SBSEND bit is cleared. If the address sent is a header of 10-bit address, the hardware sets ADD10S END bit after sending header and software should clear the ADD10SEND bit by reading I2C_STAT0 and writing 10-bit lower address to I2C_DATA.

4. After the 7-bit or 10-bit address is sent, the I2C hardware sets the ADDSEND bit and software should clear the ADDSEND bit by reading I2C_STAT0 and then I2C_STAT1.

5. Now I2C enters data transmission stage and hardware sets TBE bit because both the shift register and data register I2C_DATA are empty. Software now write the first byte data to I2C_DATA register, but the TBE is not cleared because the write byte in I2C_DATA is moved to internal shift register immediately. The I2C begins to transmit data to I2C bus as soon as shift register is not empty.

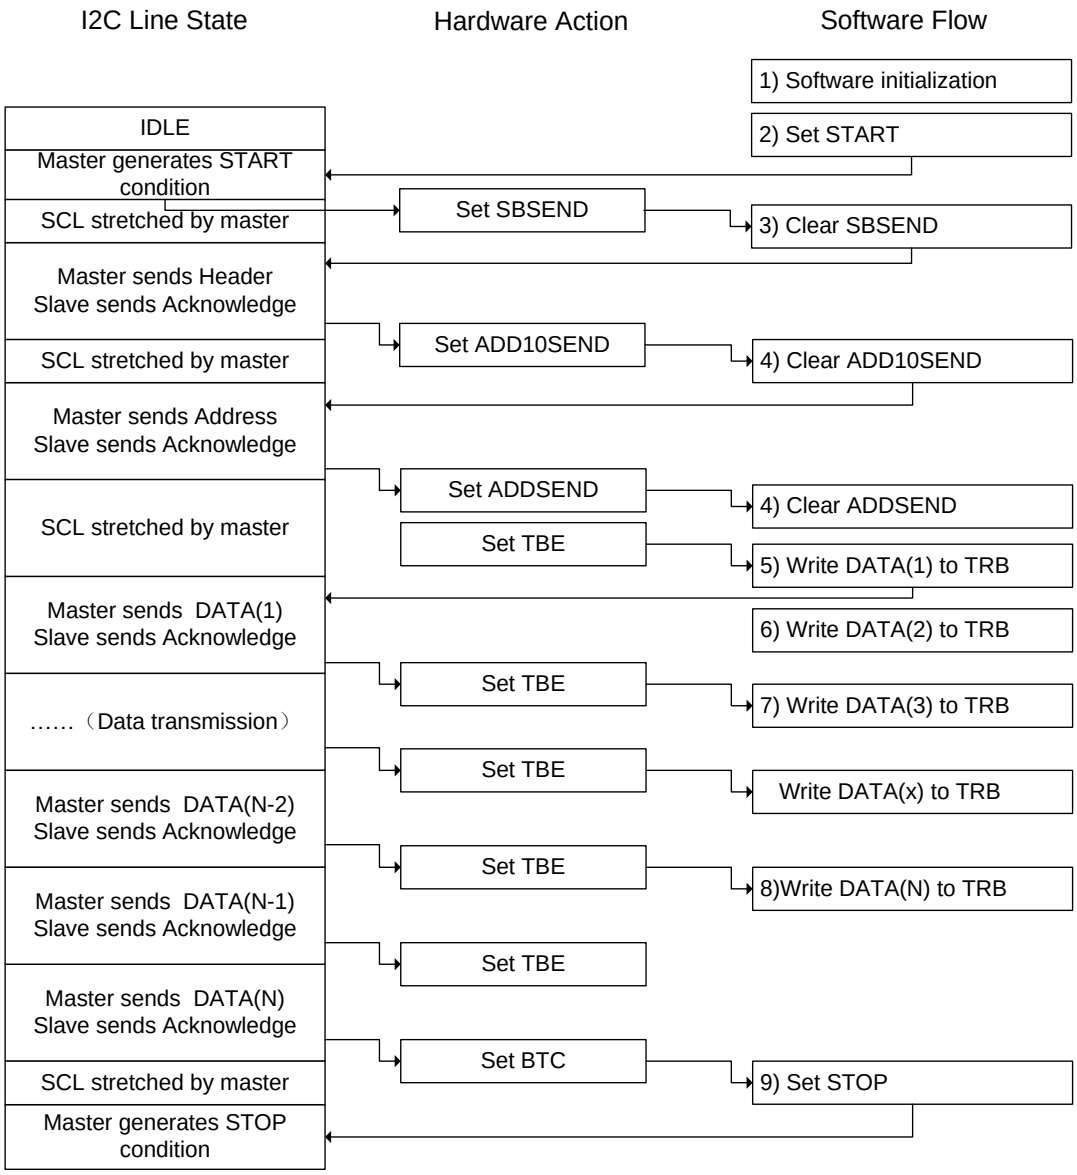
6. During the first byte's transmission, software can write the second byte to I2C_DATA, and this time TBE is cleared because neither I2C_DATA nor shift register is empty.

7. Any time TBE is set, software can write a byte to I2C_DATA as long as there are still data to be transmitted.

8. During the second last byte's transmission, software write the last data to I2C_DATA to clear the TBE flag and doesn't care TBE anymore. So TBE will be asserted after the byte's transmission and not cleared until a STOP condition.

9. After sending the last byte, I2C master sets BTC bit because both shift register and I2C_DATA are empty. Software should program a STOP request now, and the I2C clears both TBE and BTC flags after sending a STOP condition.

Figure 20-11. Programming model for master transmitting



Programming model in master receiving mode

In master receiving mode, a master is responsible for generating NACK for the last byte reception and then sending STOP condition on I2C bus. So, special attention should be paid to ensure the correct ending of data reception. Two solutions for master receiving are provided here for your application: Solution A and B. Solution A requires the software's quick response to I2C events, while Solution B doesn't.

Solution A

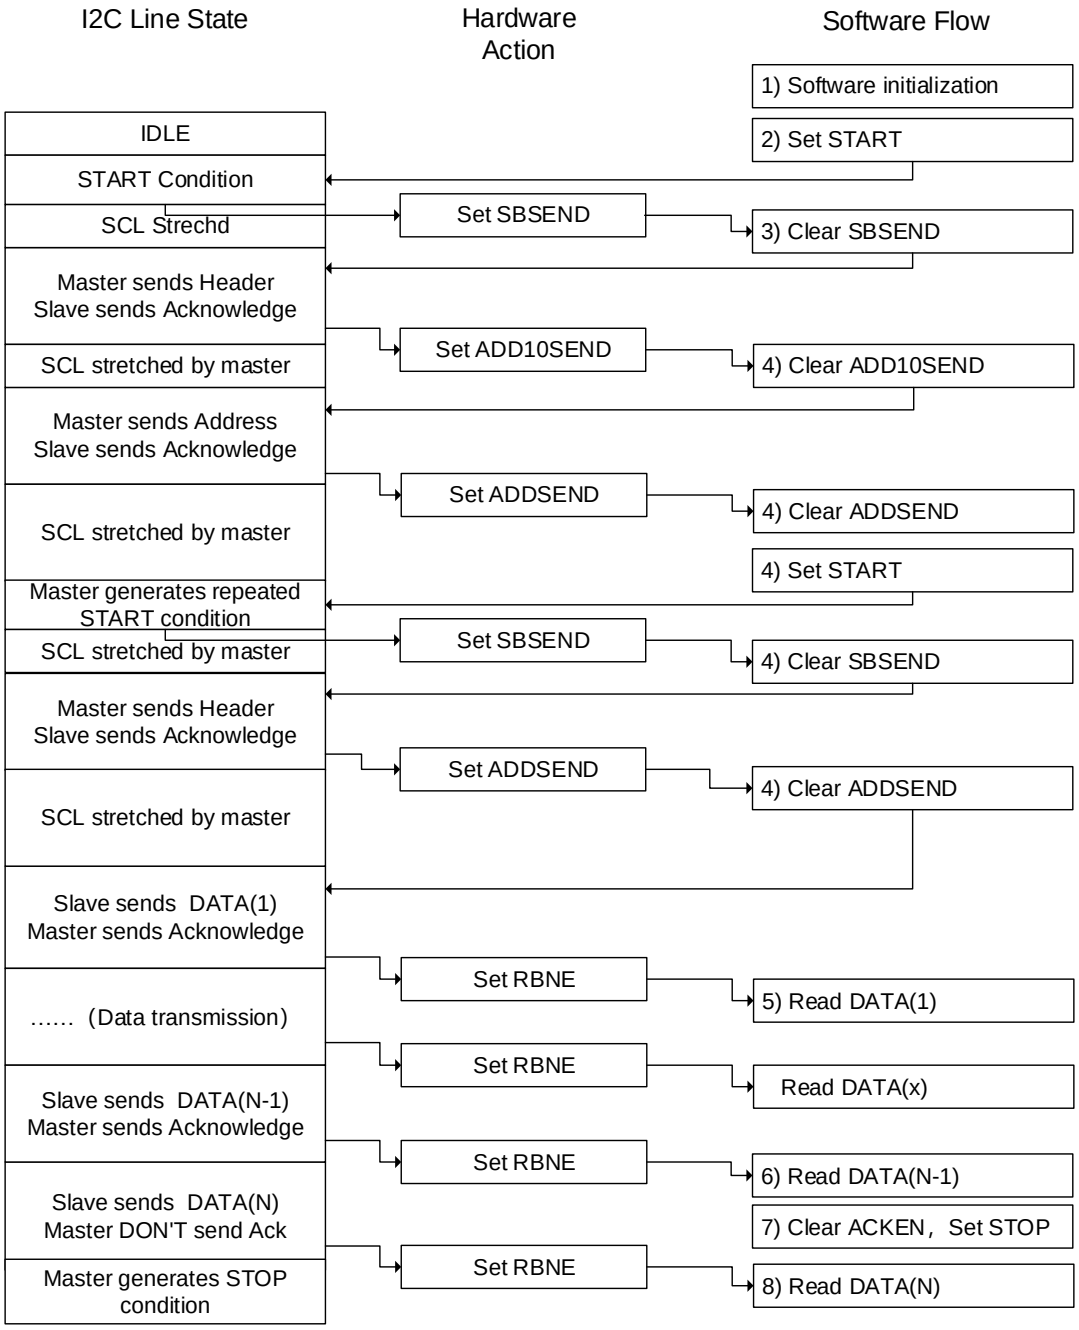
1. First of all, software should enable I2C peripheral clock as well as configure clock related registers in I2C_CTL1 to make sure correct I2C timing. After enabled and configured, I2C operates in its default slave state and waits for START condition followed by address

on I2C bus.

2. Software set START bit requesting I2C to generate a START condition to I2C bus.
3. After sending a START condition, the I2C hardware sets the SBSEND bit in I2C status register and enters master mode. Now software should clear the SBSEND bit by reading I2C_STAT0 and then writing a 7-bit address or header of a 10-bit address to I2C_DATA. I2C begins to send address or header to I2C bus as soon as SBSEND bit is cleared. If the address sent is a header of 10-bit address, the hardware sets ADD10SEND bit after sending header and software should clear the ADD10SEND bit by reading I2C_STAT0 and writing 10-bit lower address to I2C_DATA.
4. After the 7-bit or 10-bit address is sent, the I2C hardware sets the ADDSEND bit and software should clear the ADDSEND bit by reading I2C_STAT0 and then I2C_STAT1. If the address is in 10-bit format, software should then set START bit again to generate a repeated START condition on I2C bus and SBSEND is set after the repeated START is sent. Software should clear the SBSEND bit by reading I2C_STAT0 and writing header to I2C_DATA. Then the header is sent out to I2C bus, and ADDSEND is set again. Software should again clear ADDSEND by reading I2C_STAT0 and then I2C_STAT1.
5. As soon as the first byte is received, RBNE is set by hardware. Software now can read the first byte from I2C_DATA and RBNE is cleared as well.
6. Any time RBNE is set, software can read a byte from I2C_DATA.
7. After the second last byte is received, the software should clear ACKEN bit and set STOP bit. These actions should complete before the end of the last byte's receiving to ensure that NACK is sent for the last byte.
8. After last byte is received, RBNE is set. Software reads the last byte. I2C doesn't send ACK to the last byte and generate a STOP condition after the transmission of the last byte.

Above steps require byte number N>1. If N=1, Step 7 should be performed after Step 4 and completed before the end of the single byte's receiving.

Figure 20-12. Programming model for master receiving using Solution A



Solution B

1. First of all, software should enable I2C peripheral clock as well as configure clock related registers in I2C_CTL1 to make sure correct I2C timing. After enabled and configured, I2C operates in its default slave state and waits for START condition followed by address on I2C bus.

2. Software set START bit requesting I2C to generate a START condition to I2C bus.

3. After sending a START condition, the I2C hardware sets the SBSEND bit in I2C status register and enters master mode. Now software should clear the SBSEND bit by reading I2C_STAT0 and then writing a 7-bit address or header of a 10-bit address toI2C_DATA.

I2C begins to send address or header to I2C bus as soon as SBSEND bit is cleared. If the address sent is a header of 10-bit address, the hardware sets ADD10SEND bit after sending header and software should clear the ADD10SEND bit by reading I2C_STAT0 and writing 10-bit lower address toI2C_DATA.

4. After the 7-bit or 10-bit address is sent, the I2C hardware sets the ADDSEND bit and software should clear the ADDSEND bit by reading I2C_STAT0 and then I2C_STAT1. If the address is in 10-bit format, software should then set STARTbit again to generate a repeated START condition on I2C bus and SBSEND is set after the repeated START is sent out. Software should clear the SBSEND bit by reading I2C_STAT0 and writing header toI2C_DATA. Then the header is sent out to I2C bus, and ADDSEND is set again. Software should again clear ADDSEND by reading I2C_STAT0 and then I2C_STAT1.
5. As soon as the first byte is received, RBNE is set by hardware. Software now can read the first byte from I2C_DATA and RBNE is cleared as well.
6. Any time RBNE is set, software can read a byte from I2C_DATA until the master receives N-3 bytes.

As shown in ***Figure 20-13. Programming model for master receiving using solution B***, the N-2 byte is not read out by software, so after the N-1 byte is received, both BTC and RBNE are asserted. The bus is stretched by master to prevent the reception of the last byte. Then software should clear ACKEN bit.

7. Software reads out N-2 byte, clearing BTC. After this the N-1 byte is moved from shift register to I2C_DATA and bus is released and begins to receive the last byte.
8. After last byte is received, both BTC and RBNE is set again. Software sets STOP bit and master sends out a STOP condition on bus.
9. Software reads the N-1 byte, clearing BTC. After this the last byte is moved from shift register to I2C_DATA.
10. Software reads the last byte, clearing RBNE.

Above steps require that byte number N>2. N=1 or N=2 are similar:

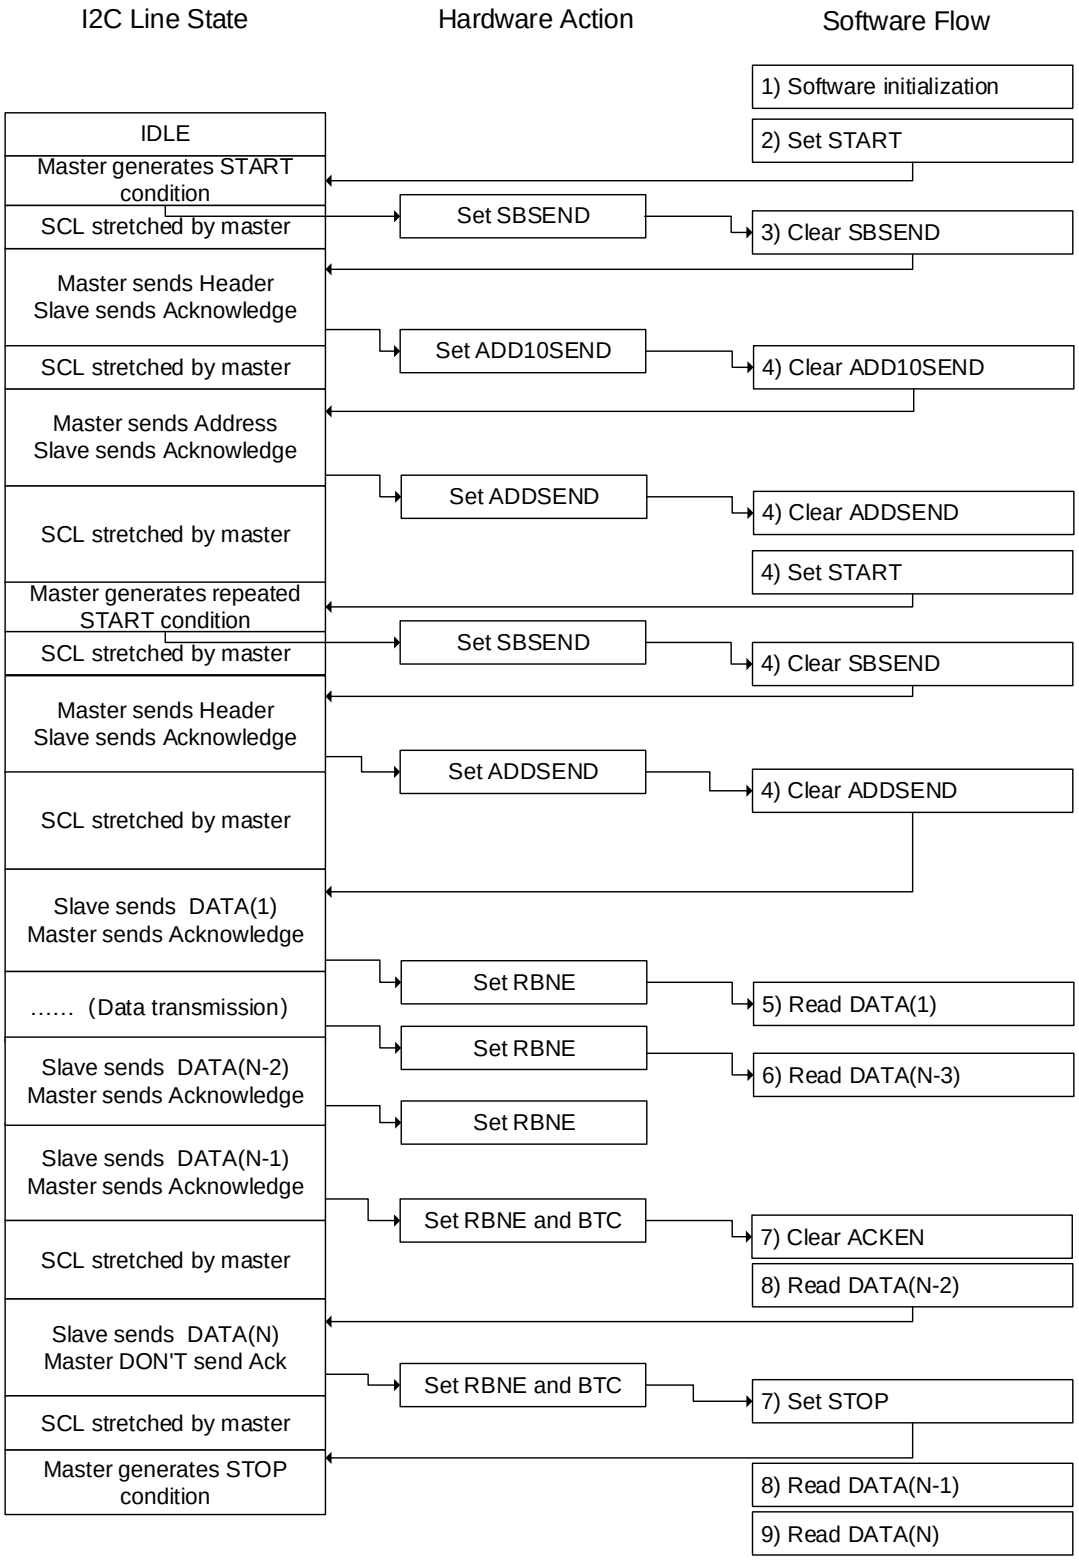
N=1

In Step4, software should reset ACK bit before clearing ADDSEND bit and set STOP bit after clearing ADDSEND bit. Step 5 is the last step when N=1.

N=2

In Step 2, software should set POAP bit before set START bit. In Step 4, software should reset ACKEN bit before clearing ADDSEND bit. In Step 5, software should wait until BTC is set and then set STOP bit and reads I2C_DATA twice.

Figure 20-13. Programming model for master receiving using solution B



20.3.8. Use DMA for data transfer

As is shown in Programming Model, each time TBE or RBNE is asserted, software should write or read a byte, this may cause CPU's high overload. The DMA controller can be used to process TBE and RBNE flag: each time TBE or RBNE is asserted, DMA controller does a read or write operation automatically.

The DMA request is enabled by the DMAON bit in the I2C_CTL1 register. This bit should be set after clearing the ADDSEND status. If the SCL line stretching function is disabled for a slave device, the DMAON bit should be set before the ADDSEND event.

Refer to the specification of the DMA controller for the configuration method of a DMA stream. The DMA controller must be configured and enabled before I2C transfer. When the configured number of byte has been transferred, the DMA controller generates End of Transfer (EOT) interrupt.

When a master receives two or more bytes, the DMALST bit in the I2C_CTL1 register should be set. The I2C master will not send NACK after the last byte. The software can set the STOP bit to generate a stop condition in the ISR of the DMA EOT interrupt.

When a master receives only one byte, the ACKEN bit must be cleared before clearing the ADDSEND status. Software can set the STOP bit to generate a stop condition after clearing the ADDSEND status, or in the ISR of the DMA EOT interrupt.

20.3.9. Packet error checking

There is a CRC-8 calculator in I2C block to perform Packet Error Checking for I2C data. The polynomial of the CRC is x8 + x2 + x + 1 which is compatible with the SMBus protocol. If enabled by setting PECEN bit, the PEC will calculate all the data(including address) transmitted through I2C. I2C is able to send out the PEC value after the last data byte or check the received PEC value with its calculated PEC using the PECTRANS bit. In DMA mode, the I2C will send or check PEC value automatically if PECEN bit is set.

20.3.10. SMBus support

The System Management Bus (abbreviated to SMBus or SMB) is a single-ended simple two-wire bus for the purpose of lightweight communication. Most commonly it is found in computer motherboards for communication with power source for ON/OFF instructions.It is derived from I2C for communication with low-bandwidth devices on a motherboard, especially power related chips such as a laptop's rechargeable battery subsystem (see Smart Battery Data).

SMBus protocol

Each message transaction on SMBus follows the format of one of the defined SMBus protocols. The SMBus protocols are a subset of the data transfer formats defined in the I2C specifications. I2C devices that can be accessed through one of the SMBus protocols are

compatible with the SMBus specifications. I2C devices that do not adhere to these protocols cannot be accessed by standard methods as defined in the SMBus and Advanced Configuration and Power Management Interface (abbreviated to ACPI) specifications.

Address resolution protocol

The SMBus uses I2C hardware and I2C hardware addressing, but adds second-level software for building special systems. Additionally, its specifications include an Address Resolution Protocol that can make dynamic address allocations. Dynamic reconfiguration of the hardware and software allow bus devices to be ‘hot-plugged’ and used immediately, without restarting the system. The devices are recognized automatically and assigned unique addresses. This advantage results in a plug-and-play user interface. In both those protocols there is a very useful distinction made between a System Host and all the other devices in the system that can have the names and functions of masters or slaves.

Time-out feature

SMBus has a time-out feature which resets devices if a communication takes too long. This explains the minimum clock frequency of 10 kHz to prevent locking up the bus. I2C can be a ‘DC’ bus, meaning that a slave device stretches the master clock when performing some routine while the master is accessing it. This will notify to the master that the slave is busy but does not want to lose the communication. The slave device will allow continuation after its task is completed. There is no limit in the I2C bus protocol as to how long this delay can be, whereas for a SMBus system, it would be limited to 35ms. SMBus protocol just assumes that if something takes too long, then it means that there is a problem on the bus and that all devices must reset in order to clear this mode. Slave devices are not allowed to hold the clock low too long.

Packet error checking

SMBus 2.0 and 1.1 allow Packet Error Checking (PEC). In that mode, a PEC (packet error code) byte is appended at the end of each transaction. The byte is calculated as CRC-8 checksum, calculated over the entire message including the address and read/write bit. The polynomial used is x8+x2+x+1 (the CRC-8-ATM HEC algorithm, initialized to zero).

SMBus alert

The SMBus has an extra optional shared interrupt signal called SMBALERT# which can be used by slaves to tell the host to ask its slaves about events of interest. SMBus also defines a less common "Host Notify Protocol", providing similar notifications but passing more data and building on the I2C multi-master mode.

SMBus programming flow

The programming flow for SMBus is similar to normal I2C. In order to use SMBus mode, the application should configure several SMBus specific registers, response to some SMBus

specific flags and implement the upper protocols described in SMBus specification.

1. Before communication, SMBEN bit in I2C_CTL0 should be set and SMBSEL and ARPEN bits should be configured to desired value.
2. In order to support address resolution protocol (ARP) (ARPEN=1), the software should response to HSTSMB flag in SMBus Host Mode (SMBTYPE =1) or DEFSMB flag in SMBus Device Mode, and implement the function of ARP protocol.
3. In order to support SMBus Alert Mode, the software should response to SMBALT flag and implement the related function.

20.3.11. Status, errors and interrupts

There are several status and error flags in I2C, and interrupt may be asserted from these flags by setting some register bits (refer to I2C register for detail).

Table 20-2. Event status flags

Event Flag Name	Description
SBSEND	START condition sent (master)
ADDSEND	Address sent or received
ADD10SEND	Header of 10-bit address sent
STPDET	STOP condition detected
BTC	Byte transmission completed
TBE	I2C_DATA is empty when transmitting
RBNE	I2C_DATA is not empty when receiving

Table 20-3. I2C error flags

I2C Error Name	Description
BERR	Bus error
LOSTARB	Arbitration lost
OUERR	Over-run or under-run when SCL stretch is disabled.
AERR	No acknowledge received
PECERR	CRC value doesn’t match
SMBTO	Bus timeout in SMBus mode
SMBALT	SMBus Alert

20.4. Register definition

I2C0 start address: 0x4000 5400

I2C1 start address: 0x4000 5800

I2C2 start address: 0x4000 C000

20.4.1. Control register 0 (I2C_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRESET	Reserved	SALT	PECTRANS	POAP	ACKEN	STOP	START	DISSTRC	GCEN	PECEN	ARPEN	SMBSEL	Reserved	SMBEN	I2CEN
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw

Bits	Fields	Descriptions
15	SRESET	Software reset I2C, software should wait until the I2C lines are released to reset the I2C 0: I2C is not under reset 1: I2C is under reset
14	Reserved	Must be kept the reset value
13	SALT	SMBus Alert. Issue alert through SMBA pin. Software can set and clear this bit and hardware can clear this bit. 0: Don’t issue alert through SMBA pin 1: Issue alert through SMBA pin
12	PECTRANS	PEC Transfer Software set and clear this bit while hardware clears this bit when PEC is transferred or START/STOP condition detectedor I2CEN=0 0: Don’t transfer PEC value 1: Transfer PEC
11	POAP	Position of ACK and PEC when receiving This bit is set and cleared by software and cleared by hardware when I2CEN=0 0: ACKEN bit specifies whether to send ACK or NACK for the current byte that is being received. PECTRANS bit indicates that the current receiving byte is a PEC byte 1: ACKEN bit specifies whether to send ACK or NACK for the next byte that is to be received, PECTRANS bit indicates the next byte that is to be received is a PEC

		byte
10	ACKEN	Whether or not to send an ACK This bit is set and cleared by software and cleared by hardware when I2CEN=0 0: ACK will not be sent 1: ACK will be sent
9	STOP	Generate a STOP condition on I2C bus This bit is set and cleared by software and set by hardware when SMBUs timeout and cleared by hardware when STOP condition detected. 0: STOP will not be sent 1: STOP will be sent
8	START	Generate a START condition on I2C bus This bit is set and cleared by software and cleared by hardware when START condition detected or I2CEN=0 0: START will not be sent 1: START will be sent
7	DISSTRC	Whether to stretch SCL low when data is not ready in slave mode. This bit is set and cleared by software. 0: SCL Stretching is enabled 1: SCL Stretching is disabled
6	GCEN	Whether or not to response to a General Call (0x00) 0: Slave won't response to a General Call 1: Slave will response to a General Call
5	PECEN	PEC Calculation Switch 0: PEC Calculation off 1: PEC Calculation on
4	ARPEN	ARP protocol in SMBus switch 0: ARP is disabled 1: ARP is enabled
3	SMBSEL	SMBusType Selection 0: Device 1: Host
2	Reserved	Must keep the reset value
1	SMBEN	SMBus/I2C mode switch 0: I2C mode 1: SMBus mode
0	I2CEN	I2C peripheral enable 0: I2C is disabled 1: I2C is enabled

20.4.2. Control register 1 (I2C_CTL1)

Address offset: 0x04

Reset value: 0x0000

This register can be accessed by half-word(16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			DMALST	DMAON	BUFIE	EVIE	ERRIE	Reserved		I2CCLK[5:0]					
			rw	rw	rw	rw	rw			rw					

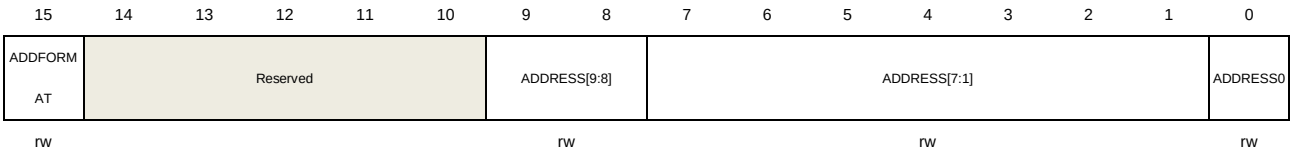
Bits	Fields	Descriptions
15:13	Reserved	Must be kept the reset value
12	DMALST	Flag indicating DMA last transfer 0: Next DMA EOT is not the last transfer 1: Next DMA EOT is the last transfer
11	DMAON	DMA mode switch 0: DMA mode disabled 1: DMA mode enabled
10	BUFIE	Buffer interrupt enable 0: No interrupt asserted when TBE = 1 or RBNE = 1 1: Interrupt asserted when TBE = 1 or RBNE = 1 if EVIE=1
9	EVIE	Event interrupt enable 0: Event interrupt disabled 1: Event interrupt enabled, means that interrupt will be generated when SBSEND, ADDSEND, ADD10SEND, STPDET or BTC flag asserted or TBE=1 or RBNE=1 if BUFIE=1.
8	ERRIE	Error interrupt enable 0: Error interrupt disabled 1: Error interrupt enabled, means that interrupt will be generated when BERR, LOSTARB, AERR, OUERR, PECERR, SMBTO or SMBALT flag asserted.
7:6	Reserved	Must be kept the reset value
5:0	I2CCLK[5:0]	I2C Peripheral clock frequency I2CCLK[5:0]should be the frequency of input APB1 clock in MHz which is at least 2. 000000 - 000001: Not allowed 000010 - 111100: 2 MHz~50MHz 111101 - 111111: Not allowed due to the limitation of APB1 clock **Note:** In I2C standard mode, the frequencies of APB1 must be equal or greater than 2MHz. In I2C fast mode, the frequencies of APB1 must be equal or greater than

8MHz. In I2C fast mode plus, the frequencies of APB1 must be equal or greater than 24MHz.

20.4.3. Slave address register 0 (I2C_SADDR0)

Address offset: 0x08
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

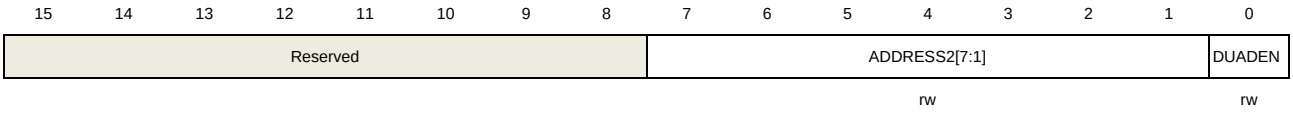


Bits	Fields	Descriptions
15	ADDFORMAT	Address mode for the I2C slave 0: 7-bit Address 1: 10-bit Address
14:10	Reserved	Must be kept the reset value
9:8	ADDRESS[9:8]	Highest two bits of a 10-bit address
7:1	ADDRESS[7:1]	7-bit address or bits 7:1 of a 10-bit address
0	ADDRESS0	Bit 0 of a 10-bit address

20.4.4. Slave address register 1 (I2C_SADDR1)

Address offset: 0x0C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



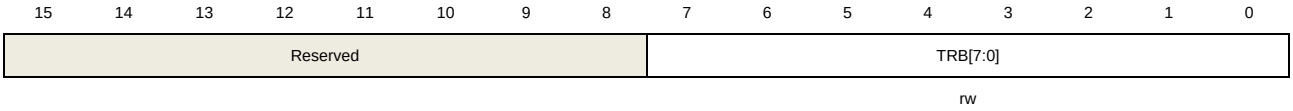
Bits	Fields	Descriptions
15:8	Reserved	Must be kept the reset value
7:1	ADDRESS2[7:1]	Second I2C address for the slave in Dual-Address mode
0	DUADEN	Dual-Address mode switch 0: Dual-Address mode disabled 1: Dual-Address mode enabled

20.4.5. Transfer buffer register (I2C_DATA)

Address offset: 0x10

Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



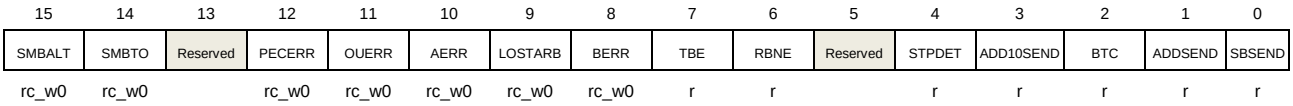
Bits	Fields	Descriptions
15:8	Reserved	Must be kept the reset value
7:0	TRB[7:0]	Transmission or reception data buffer

20.4.6. Transfer status register 0 (I2C_STAT0)

Address offset: 0x14

Reset value: 0x0000

This register can be accessed byhalf-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15	SMBALT	SMBus Alert status This bit is set by hardware and cleared by writing 0. 0: SMBA pin not pulled down (device mode) or no Alert detected (host mode) 1: SMBA pin pulled down (device mode) or Alert detected (host mode)
14	SMBTO	Timeout signal in SMBus mode This bit is set by hardware and cleared by writing 0. 0: No timeout error 1: Timeout event occurs (SCL is low for 25 ms)
13	Reserved	Must keep the reset value
12	PECERR	PEC error when receiving data This bit is set by hardware and cleared by writing 0. 0: Received PEC and calculated PEC match 1: Received PEC and calculated PEC don’t match, I2C will send NACK careless of ACKEN bit.

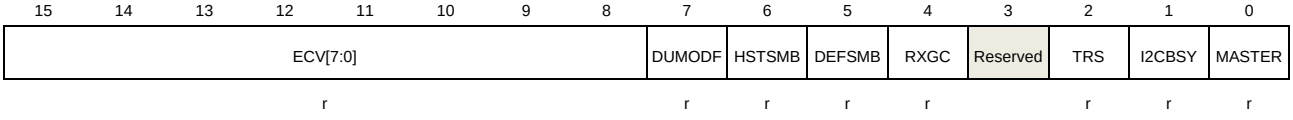
11	OUERR	Over-run or under-run situation occurs in slave mode, when SCL stretching is disabled. In slave receiving mode, if the last byte in I2C_DATA is not read out while the following byte is already received, over-run occurs. In slave transmitting mode, if the current byte is already sent out, while the I2C_DATA is still empty, under-run occurs. This bit is set by hardware and cleared by writing 0. 0: No over-run or under-run occurs 1: Over-run or under-run occurs
10	AERR	Acknowledge Error This bit is set by hardware and cleared by writing 0. 0: No Acknowledge Error 1: Acknowledge Error
9	LOSTARB	Arbitration Lost in master mode This bit is set by hardware and cleared by writing 0. 0: No Arbitration Lost 1: Arbitration Lost occurs and the I2C block changes back to slave mode.
8	BERR	A bus error indicates an unexpected START or STOP condition on I2C bus This bit is set by hardware and cleared by writing 0. 0: No bus error 1: A bus error detected
7	TBE	I2C_DATA is Empty during transmitting This bit is set by hardware after it moves a byte from I2C_DATA to shift register and cleared by writing a byte to I2C_DATA. If both the shift register and I2C_DATA are empty, writing I2C_DATA won't clear TBE (refer to Programming Model for detail). 0:I2C_DATA is not empty 1:I2C_DATA is empty, software can write
6	RBNE	I2C_DATA is not Empty during receiving This bit is set by hardware after it moves a byte from shift register to I2C_DATA and cleared by reading it. If both BTC and RBNE are asserted, reading I2C_DATA won't clear RBNE because the shift register's byte is moved to I2C_DATA immediately. 0: I2C_DATA is empty 1: I2C_DATA is not empty, software can read
5	Reserved	Must be kept the reset value
4	STPDET	STOP condition detected in slave mode This bit is set by hardware and cleared by reading I2C_STAT0 and then writing CTLR1 0: STOP condition not detected in slave mode 1: STOP condition detected in slave mode

3	ADD10SEND	Header of 10-bit address is sent in master mode This bit is set by hardware and cleared by reading I2C_STAT0 and writing I2C_DATA. 0: No header of 10-bit address sent in master mode 1: Header of 10-bit address is sent in master mode
2	BTC	Byte transmission completed. If a byte is already received in shift register but I2C_DATA is still full in receiving mode or a byte is already sent out from shift register but I2C_DATA is still empty in transmitting mode, the BTC flag is asserted if SCL stretching enabled. This bit is set by hardware. This bit can be cleared by 3 ways as follow: 1. Reading I2C_STAT0 followed by reading or writing 2. Hardware clearing: sending the STOP condition or START condition 3. Bit 0 (I2CEN bit) of the I2C_CTL0 is reset. 0: BTC not asserted 1: BTC asserted
1	ADDSEND	Address is sent in master mode or received and matches in slave mode. This bit is set by hardware and cleared by reading I2C_STAT0 and reading I2C_STAT1. 0: No address sent or received 1: Address sent out in master mode or a matched address is received in salve mode
0	SBSEND	START condition sent out in master mode This bit is set by hardware and cleared by reading I2C_STAT0 and writing I2C_DATA 0: No START condition sent 1: START condition sent

20.4.7. Transfer status register 1 (I2C_STAT1)

Address offset: 0x18
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)



Bits	Fields	Descriptions
15:8	ECV[7:0]	Packet Error Checking Value that calculated by hardware when PEC is enabled.
7	DUMODF	Dual Flag in slave mode indicating which address is matched in Dual-Address

		mode This bit is cleared by hardware after a STOP or a START condition or I2CEN=0 0: SADDR0 address matches 1: SADDR1 address matches
6	HSTSMB	SMBus Host Header detected in slave mode This bit is cleared by hardware after a STOP or a START condition or I2CEN=0 0: No SMBus Host Header detected 1: SMBus Host Header detected
5	DEFSMB	Default address of SMBusDevice This bit is cleared by hardware after a STOP or a START condition or I2CEN=0. 0: The default address has not been received 1: The default address has been received for SMBus Device
4	RXGC	General call address (00h) received. This bit is cleared by hardware after a STOP or a START condition or I2CEN=0. 0: No general call address (00h) received 1: General call address (00h) received
3	Reserved	Must be kept the reset value
2	TRS	Whether the I2C is a transmitter or a receiver This bit is cleared by hardware after a STOP or a START condition or I2CEN=0 or LOSTARB=1. 0: Receiver 1: Transmitter
1	I2CBSY	Busy flag This bit is cleared by hardware after a STOP condition 0: No I2C communication. 1: I2C communication active.
0	MASTER	A flag indicating whether I2C block is in master or slave mode. This bit is cleared by hardware after a STOP or a START condition or I2CEN=0 or LOSTARB=1. 0: Slave mode 1: Master mode

20.4.8. Clock configure register (I2C_CKCFG)

Address offset: 0x1C
Reset value: 0x0000

This register can be accessed by half-word (16-bit) or word (32-bit)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FAST	DTCY	Reserved		CLKC[11:0]											

rw rw rw

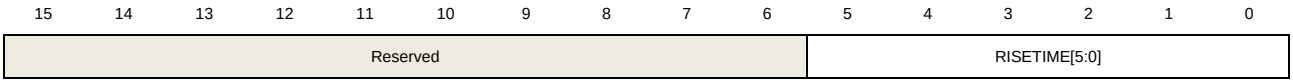
Bits	Fields	Descriptions
15	FAST	I2C speed selection in master mode 0: Standard speed 1: Fast speed
14	DTCY	Duty cycle in fast mode 0:$T_{low}/T_{high} = 2$ 1: $T_{low}/T_{high} = 16/9$
13:12	Reserved	Must be kept the reset value
11:0	CLKC[11:0]	I2C Clock control in master mode In standard speed mode: $T_{high} = T_{low} = CLKC * T_{PCLK1}$ In fast speed mode if DTCY=0: $T_{high} = CLKC * T_{PCLK1}$ ，$T_{low} = 2 * CLKC * T_{PCLK1}$ In fast speed mode if DTCY=1: $T_{high} = 9 * CLKC * T_{PCLK1}$ ，$T_{low} = 16 * CLKC * T_{PCLK1}$

20.4.9. Rise time register (I2C_RT)

Address offset: 0x20

Reset value: 0x0002

This register can be accessed by half-word (16-bit) or word (32-bit)



rw

Bits	Fields	Descriptions
15:6	Reserved	Must be kept the reset value
5:0	RISETIME[5:0]	Maximum rise time in master mode The RISETIME value should be the maximum SCL rise time incremented by 1.

21. Serial peripheral interface/Inter-IC sound (SPI/I2S)

21.1. Overview

The SPI/I2S module can communicate with external devices using the SPI protocol or the I2S audio protocol.

The Serial Peripheral Interface (SPI) provides a SPI protocol of data transmission and reception function in master or slave mode. Both full-duplex and simplex communication modes are supported, with hardware CRC calculation and checking. Quad-SPI master mode is also supported in SPI0.

The inter-IC sound (I2S) supports four audio standards: I2S Phillips standard, MSB justified standard, LSB justified standard, and PCM standard. I2S works at either master or slave mode for transmission and reception.

21.2. Characteristics

21.2.1. SPI characteristics

- Master or slave operation with full-duplex or simplex mode.
- Separate transmit and receive buffer, 16 bits wide.
- Data frame size can be 8 or 16 bits.
- Bit order can be LSB first or MSB first.
- Software and hardware NSS management.
- Hardware CRC calculation, transmission and checking.
- Transmission and reception using DMA.
- Quad-SPI configuration available in master mode (only in SPI0).

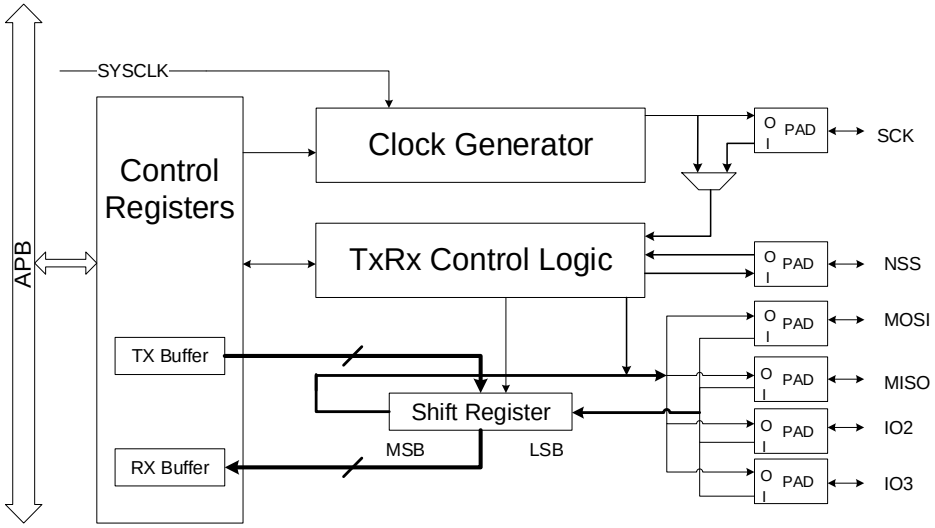
21.2.2. I2S characteristics

- Master or slave operation with transmission or reception mode.
- Four I2S standards supported: Phillips, MSB justified, LSB justified and PCM standard.
- Data length can be 16 bits, 24 bits or 32 bits.
- Channel length can be 16 bits or 32 bits.
- Transmission and reception using a 16 bits wide buffer.
- Audio sample frequency can be 8 kHz to 192 kHz using I2S clock divider.
- Programmable idle state clock polarity.

- Master clock (MCK) can be output.
- Transmission and reception using DMA.

21.3. SPI block diagram

Figure 21-1. Block diagram of SPI



21.4. SPI signal description

21.4.1. Normal configuration (Not Quad-SPI Mode)

Table 21-1. SPI signal description

Pin Name	Direction	Description
SCK	I / O	Master: SPI Clock Output Slave: SPI Clock Input
MISO	I / O	Master: Data reception line Slave: Data transmission line Master with Bidirectional mode: Not used Slave with Bidirectional mode: Data transmission and reception Line.
MOSI	I / O	Master: Data transmission line Slave: Data reception line Master with Bidirectional mode: Data transmission and reception Line. Slave with Bidirectional mode: Not used
NSS	I / O	Software NSS Mode: Not Used

Pin Name	Direction	Description
		Master in Hardware NSS Mode: NSS output (NSSDRV=1) for single master or (NSSDRV=0) for multi-master application. Slave in Hardware NSS Mode: NSS input, as a chip select signal for slave.

21.4.2. Quad-SPI configuration

SPI is in single wire mode by default and enters into Quad-SPI mode after QMOD bit in SPI_QCTL register is set (only available in SPI0). Quad-SPI mode can only work at master mode.

Software is able to drive IO2 and IO3 pins high in normal Non-Quad-SPI mode by using IO23_DRV bit in SPI_QCTL register.

The SPI is connected to external devices through 6 pins in Quad-SPI mode:

Table 21-2. Quad-SPI signal description

Pin Name	Direction	Description
SCK	O	SPI Clock Output
MOSI	I / O	Transmission or Reception Data 0 line
MISO	I / O	Transmission or Reception Data 1 line
IO2	I / O	Transmission or Reception Data 2 line
IO3	I / O	Transmission or Reception Data 3 line
NSS	O	NSS output

21.5. SPI function overview

21.5.1. SPI clock timing and data format

CKPL and CKPH bits in SPI_CTL0 register decide the timing of SPI clock and data signal. The CKPL bit decides the SCK level when idle and CKPH bit decides either first or second clock edge is a valid sampling edge.

Figure 21-2. SPI timing diagram in normal mode

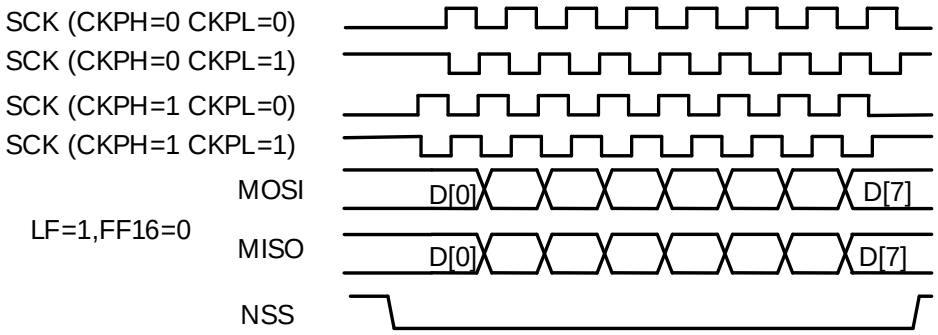


Figure 21-3. SPI timing diagram in Quad-SPI mode (CKPL=1, CKPH=1, LF=0)

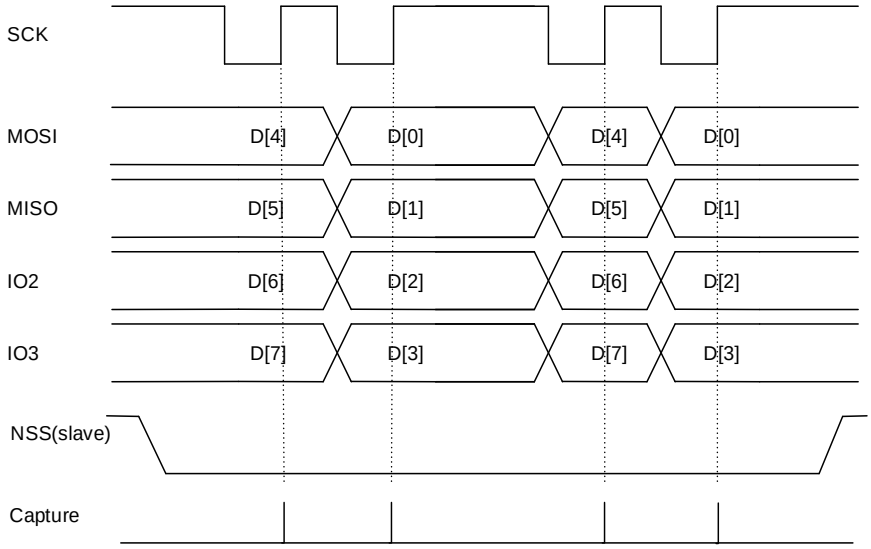

In normal mode, the length of data is configured by the FF16 bit in the SPI_CTL0 register. Data length is 16 bits if FF16=1, otherwise is 8 bits. The data frame length is fixed to 8 bits in Quad-SPI mode.

Data order is configured by LF bit in SPI_CTL0 register, and SPI will first send the LSB if LF=1, or the MSB if LF=0.

21.5.2. NSS function

Slave Mode

When slave mode is configured (MSTMOD=0), SPI gets NSS level from NSS pin in hardware NSS mode (SWNSSEN = 0) or from SWNSS bit in software NSS mode (SWNSSEN = 1) and transmits/receives data only when NSS level is low. In software NSS mode, NSS pin is not used.

Master mode

In master mode (MSTMOD=1) if the application uses multi-master connection, NSS can be configured to hardware input mode (SWNSSEN=0, NSSDRV=0) or software mode (SWNSSEN=1). Then, once the NSS pin (in hardware NSS mode) or the SWNSS bit (in software NSS mode) goes low, the SPI automatically enters to slave mode and triggers a master fault flag CONFERR.

If the application wants to use NSS line to control the SPI slave, NSS should be configured to hardware output mode (SWNSSEN=0, NSSDRV=1). NSS stays high after SPI is enabled and goes low when transmission or reception process begins.

The application may also use a general purpose IO as NSS pin to realize more flexible NSS.

21.5.3. SPI operation modes

Table 21-3. SPI operation modes

Mode	Description	Register Configuration	Data Pin Usage
MFD	Master Full-Duplex	MSTMOD = 1 RO = 0 BDEN = 0 BDOEN: Don't care	MOSI: Transmission MISO: Reception
MTU	Master Transmission with unidirectional connection	MSTMOD = 1 RO = 0 BDEN = 0 BDOEN: Don't care	MOSI: Transmission MISO: Not used
MRU	Master Reception with unidirectional connection	MSTMOD = 1 RO = 1 BDEN = 0 BDOEN: Don't care	MOSI: Not used MISO: Reception
MTB	Master Transmission with bidirectional connection	MSTMOD = 1 RO = 0 BDEN = 1 BDOEN = 1	MOSI: Transmission MISO: Not used
MRB	Master Reception with bidirectional connection	MSTMOD = 1 RO = 0 BDEN = 1 BDOEN = 0	MOSI: Reception MISO: Not used
SFD	Slave Full-Duplex	MSTMOD = 0 RO = 0 BDEN = 0 BDOEN: Don't care	MOSI: Reception MISO: Transmission

Mode	Description	Register Configuration	Data Pin Usage
STU	Slave Transmission with unidirectional connection	MSTMOD = 0 RO = 0 BDEN = 0 BDOEN: Don't care	MOSI: Not used MISO: Transmission
SRU	Slave Reception with unidirectional connection	MSTMOD = 0 RO = 1 BDEN = 0 BDOEN: Don't care	MOSI: Reception MISO: Not used
STB	Slave Transmission with bidirectional connection	MSTMOD = 0 RO = 0 BDEN = 1 BDOEN = 1	MOSI: Not used MISO: Transmission
SRB	Slave Reception with bidirectional connection	MSTMOD = 0 RO = 0 BDEN = 1 BDOEN = 0	MOSI: Not used MISO: Reception

Figure 21-4. A typical Full-duplex connection

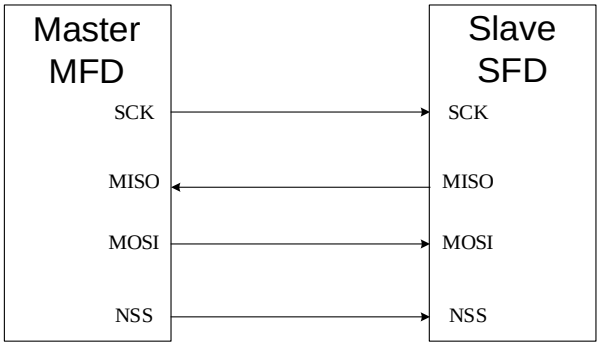

Figure 21-5. A typical simplex connection (Master: Receive, Slave: Transmit)

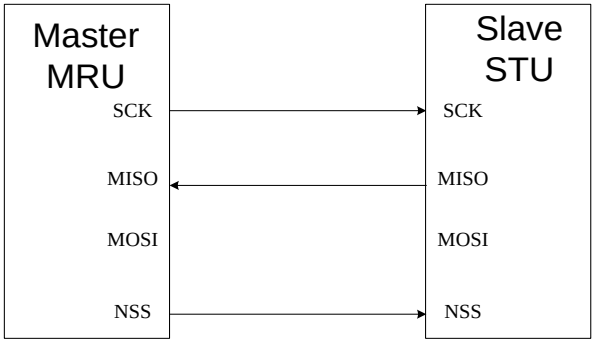

Figure 21-6. A typical simplex connection (Master: Transmit only, Slave: Receive)

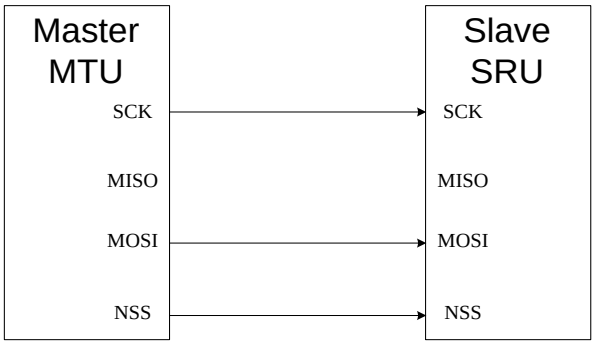

Figure 21-7. A typical bidirectional connection

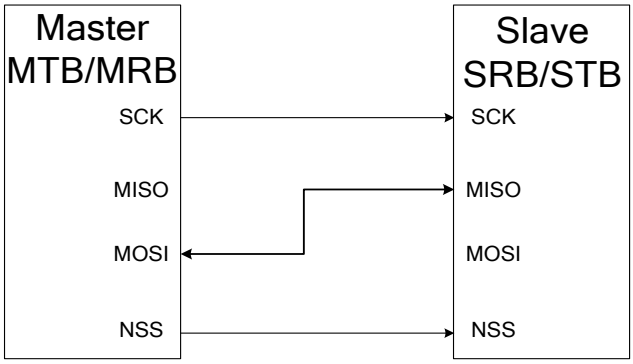


SPI initialization sequence

Before transmitting or receiving data, application should follow the SPI initialization sequence described below:

1. If master mode is used, program the PSC [2:0] bits in SPI_CTL0 register to generate SCK with desired baud rate, otherwise, ignore this step.
2. Program data format (FF16 bit in the SPI_CTL0 register).
3. Program the clock timing register (CKPL and CKPH bits in the SPI_CTL0 register).
4. Program the frame format (LF bit in the SPI_CTL0 register).
5. Program the NSS mode (SWNSSEN and NSSDRV bits in the SPI_CTL0 register) according to the application's demand as described above in ***NSS function*** section.
6. Configure MSTMOD, RO, BDEN and BDOEN depending on the operation modes described above.
7. If Quad-SPI mode is used, set the QMOD bit in SPI_QCTL register. Ignore this step if Quad-SPI mode is not used.
8. Enable the SPI (set the SPIEN bit).

SPI basic transmission and reception sequence

Transmission sequence

After the initialization sequence, the SPI is enabled and stays at idle state. In master mode, the transmission starts when the application writes a data into the transmit buffer. In slave mode the transmission starts when SCK clock signal begins to toggle at SCK pin and NSS level is low, so application should ensure that data is already written into transmit buffer before the transmission starts in slave mode.

When SPI begins to send a data frame, it loads this data frame from the data buffer to the shift register first and then begins to transmit the loaded data frame, TBE (transmit buffer empty) flag is set after the first bit of this frame is transmitted. After TBE flag is set, which means the transmit buffer is empty, the application should write SPI_DATA register again if it has more data to transmit.

In master mode, software should write the next data into SPI_DATA register before the transmission of current data frame is completed if it desires to generate continuous transmission.

Reception sequence

The incoming data will be moved from shift register to the receive buffer after the last valid sample clock and RBNE (receive buffer not empty) will be set also. The application should read SPI_DATA register to get the received data and this will clear the RBNE flag automatically. In MRU and MRB modes, hardware continuously sends clock signal to receive the next data frame, while in full-duplex master mode (MFD), hardware only receives the next data frame when the transmit buffer is not empty.

SPI operation sequence in different modes (Not Quad-SPI)

In full-duplex mode, either MFD or SFD, application should monitor the RBNE and TBE flags and follow the sequences described above.

The transmission mode (MTU, MTB, STU or STB) is similar to full-duplex mode, except that application should ignore the RBNE and OVRE bits and only perform transmission sequence described above.

In master reception mode (MRU or MRB), the behavior is different from full-duplex mode or transmission mode. In MRU or MRB mode, the SPI continuously generates SCK just after SPI is enabled, until the SPI is disabled. So the application should ignore the TBE flag and read out reception buffer in time after the RBNE flag is set, otherwise a data overrun fault will occur.

The slave reception mode (SRU or SRB) is similar to full-duplex mode, except that application should ignore the TBE flag and only perform reception sequence described above.

Quad-SPI mode operation sequence

The Quad-SPI mode is designed to control quad SPI flash.

In order to enter Quad-SPI mode, the software should first verify that the TBE bit is set and TRANS bit is cleared, then set QMOD bit in SPI_QCTL register. In Quad-SPI mode, BDEN, BDOEN, CRCEN, CRCNT, FF16, RO and LF in SPI_CTL0 register should be kept cleared and MSTMOD should be set to ensure that SPI is in master mode. SPIEN, PSC, CKPL and CKPH should be configured as desired.

There are 2 operation modes in Quad-SPI mode: quad write and quad read, decided by QRD bit in SPI_QCTL register.

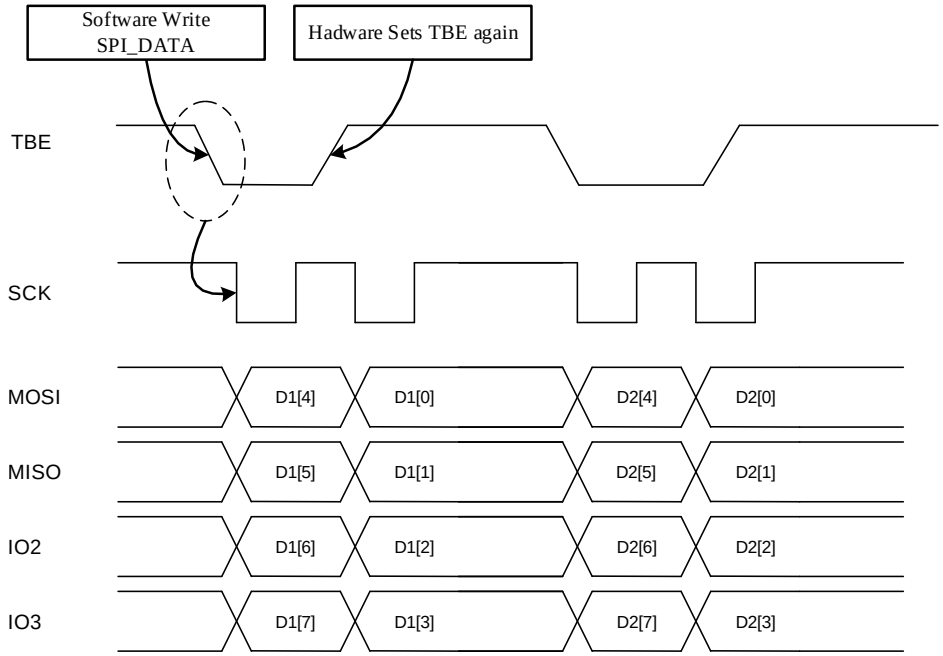
Quad write operation

SPI works in quad write mode when QMOD is set and QRD is cleared in SPI_QCTL register. In this mode, MOSI, MISO, IO2 and IO3 are all used as output pins. SPI begins to generate clock on SCK line and transmit data on MOSI, MISO, IO2 and IO3 as soon as data is written into SPI_DATA (TBE is cleared) and SPIEN is set. Once SPI starts transmission, it always checks TBE status at the end of a frame and stops when condition is not met.

The operation flow for transmitting in quad mode:

1. Configure clock prescaler, clock polarity, phase, etc. in SPI_CTL0 and SPI_CTL1 based on your application requirements.
2. Set QMOD bit in SPI_QCTL register and then enable SPI by setting SPIEN in SPI_CTL0.
3. Write the byte to SPI_DATA register and the TBE will be cleared.
4. Wait until TBE is set by hardware again before writing the next byte.

Figure 21-8. Timing diagram of quad write operation in Quad-SPI mode



Quad read operation

SPI works in quad read mode when QMOD and QRD are both set in SPI_QCTL register. In this mode, MOSI, MISO, IO2 and IO3 are all used as input pins. SPI begins to generate clock on SCK line as soon as a data is written into SPI_DATA (TBE is cleared) and SPIEN is set. Writing data into SPI_DATA is only to generate SCK clocks, so the written data can be any value. Once SPI starts transmission, it always checks SPIEN and TBE status at the end of a frame and stops when condition is not met. So, software should always write dummy data into SPI_DATA to make SPI generate SCK.

The operation flow for receiving in quad mode:

1.Configure clock prescaler, clock polarity, phase, etc. in SPI_CTL0 and SPI_CTL1 register based on your application requirements.

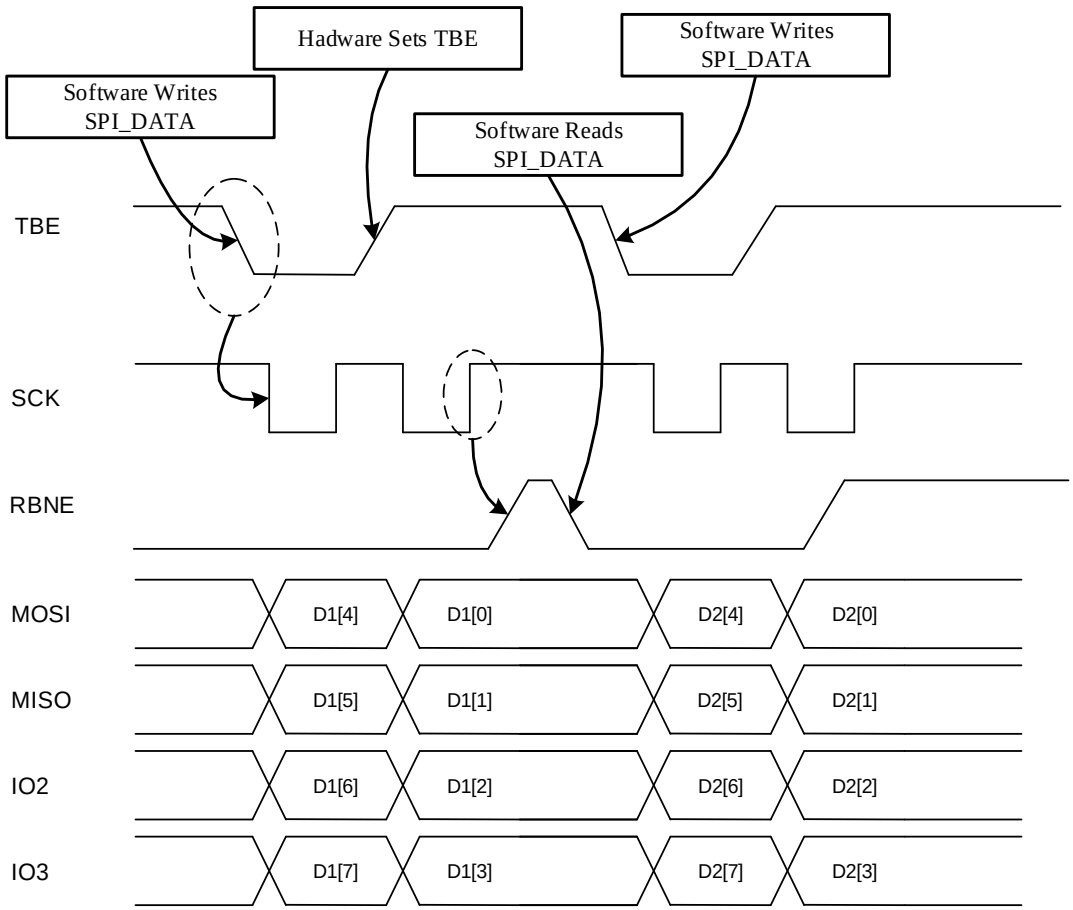
2.Set QMOD and QRD bits in SPI_QCTL register and then enable SPI by setting SPIEN in SPI_CTL0 register.

3.Write an arbitrary byte (for example, 0xFF) to SPI_DATA register.

4.Wait until the RBNE flag is set and read SPI_DATA to get the received byte.

5.Write an arbitrary byte (for example, 0xFF) to SPI_DATA to receive the next byte.

Figure 21-9. Timing diagram of quad read operation in Quad-SPI mode



SPI disabling sequence

Different sequences are used to disable the SPI in different operation modes:

MFD SFD

Wait for the last RBNE flag and then receive the last data. Confirm that TBE=1 and TRANS=0. At last, disable the SPI by clearing SPIEN bit.

MTU MTB STU STB

Write the last data into SPI_DATA and wait until the TBE flag is set and then wait until the TRANS flag is cleared. Disable the SPI by clearing SPIEN bit.

MRU MRB

After getting the second last RBNE flag, read out this data and delay for a SCK clock time and then, disable the SPI by clearing SPIEN bit. Wait until the last RBNE flag is set and read out the last data.

SRU SRB

Application can disable the SPI when it doesn't want to receive data, and then wait until the TRANS=0 to ensure the on-going transfer completes.

Quad-SPI mode

Before leaving quad wire mode or disabling SPI, software should first check that, TBE bit is set and TRANS bit is cleared, then the QMOD bit in SPI_QCTL register and SPIEN bit in SPI_CTL0 register are cleared.

21.5.4. DMA function

The DMA function frees the application from data writing and reading process during transfer, thus improving the system efficiency.

DMA function in SPI is enabled by setting DMATEN and DMAREN bits in SPI_CTL1 register. To use DMA function, application should first correctly configure DMA modules, then configure SPI module according to the initialization sequence, at last enable SPI.

After being enabled, If DMATEN is set, SPI will generate a DMA request each time TBE=1, then DMA will acknowledge to this request and write data into the SPI_DATA register automatically. If DMAREN is set, SPI will generate a DMA request each time RBNE=1, then DMA will acknowledge to this request and read data from the SPI_DATA register automatically.

21.5.5. CRC function

There are two CRC calculators in SPI: one for transmission and the other for reception. The CRC calculation uses the polynomial in SPI_CRCPOLY register.

Application can switch on the CRC function by setting CRCEN bit in SPI_CTL0 register. The CRC calculators continuously calculate CRC for each bit transmitted and received on lines, and the calculated CRC values can be read from SPI_TCRC and SPI_RCRC register.

To transmit the calculated CRC value, application should set the CRCNT bit in SPI_CTL0 register after the last data is written to the transmit buffer. In full-duplex mode (MFD or SFD) the SPI treats the incoming data as a CRC value when it transmits a CRC and will check the received CRC value. In reception mode (MRB, MRU, SRU and SRB), the application should set the CRCNT bit after the second-last data frame is received. When CRC checking fails, the CRCERR flag will be set.

If DMA function is enabled, application doesn't need to operate CRCNT bit and hardware will automatically process the CRC transmitting and checking.

21.6. SPI interrupts

21.6.1. Status flags

- Transmit buffer empty flag (TBE)

This bit is set when the transmit buffer is empty, the software can write the next data to the transmit buffer by writing the SPI_DATA register.

- Receive buffer not empty flag (RBNE)

This bit is set when receive buffer is not empty, which means that one data is received and stored in the receive buffer, and software can read the data by reading the SPI_DATA register.

- SPI Transmitting On-Going flag (TRANS)

TRANS is a status flag to indicate whether the transfer is on-going or not. It is set and cleared by internal hardware and not controlled by software. This flag doesn't generate any interrupt.

21.6.2. Error conditions

- Configuration Fault Error (CONFERR)

CONFERR is an error flag in master mode. In NSS hardware mode and the NSSDRV is not enabled, the CONFERR is set when the NSS pin is pulled low. In NSS software mode, the CONFERR is set when the SWNSS bit is 0. When the CONFERR is set, the SPIEN bit and the MSTMOD bit are cleared by hardware, the SPI is disabled and the device is forced into slave mode.

The SPIEN and MSTMOD bit are write protection until the CONFERR is cleared. The CONFERR bit of the slave cannot be set. In a multi-master configuration, the device can be in slave mode with CONFERR bit set, which means there might have been a multi-master conflict for system control.

- Rx Overrun Error (RXORERR)

The RXORERR bit is set if a data is received when the RBNE is set. That means, the last data has not been read out and the newly incoming data is received. The contents of the receive buffer are not covered by the newly incoming data, so the newly incoming data is missing.

- CRC Error (CRCERR)

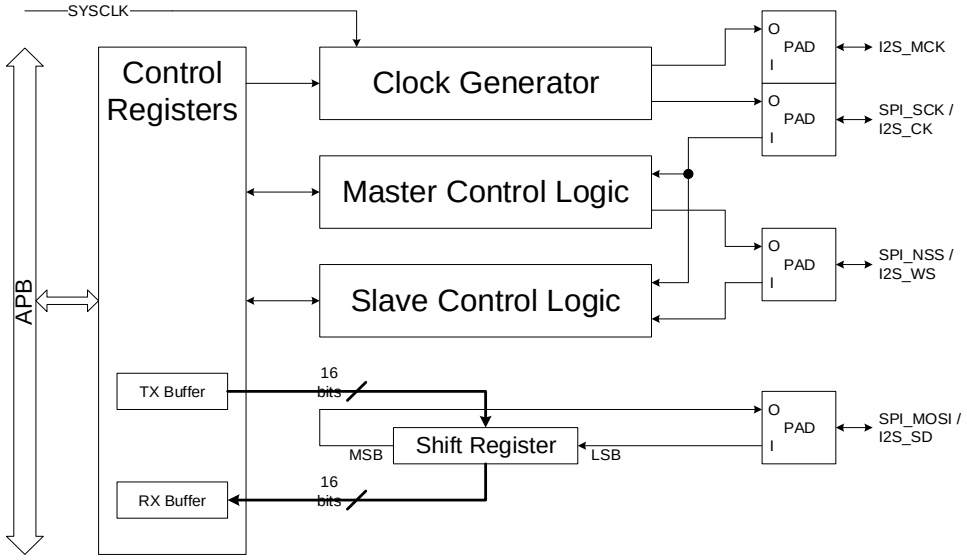
When the CRCEN bit is set, the CRC calculation result of the received data in the SPI_RCRC register is compared with the received CRC value after the last data, the CRCERR is set when they are different.

Table 21-4. SPI interrupt requests

Flag	Description	Clear Method	Interrupt Enable bit
TBE	Transmit buffer empty	Write SPI_DATA register.	TBEIE
RBNE	Receive buffer not empty	Read SPI_DATA register	RBNEIE
CONFERR	Configuration Fault Error	Read or write SPI_STAT register, then write SPI_CTL0 register.	ERRIE
RXORERR	Rx Overrun Error	Read SPI_DATA register, then read SPI_STAT register.	
CRCERR	CRC error	Write 0 to CRCERR bit	

21.7. I2S block diagram

Figure 21-10. Block diagram of I2S



There are five sub modules to support I2S function, including control registers, clock generator, master control logic, slave control logic and shift register. All the user configuration registers are implemented in the control registers module, including the TX buffer and RX buffer. The clock generator is used to produce I2S communication clock in master mode. The master control logic is implemented to generate the I2S_WS signal and control the communication in master mode. The slave control logic is implemented to control the communication in slave mode according to the received I2SCK and I2S_WS. The shift register handles the serial data transmission and reception on I2S_SD.

21.8. I2S signal description

There are four pins on the I2S interface, including I2S_CK, I2S_WS, I2S_SD and I2S_MCK. I2S_CK is the serial clock signal, which shares the same pin with SPI_SCK. I2S_WS is the frame control signal, which shares the same pin with SPI_NSS. I2S_SD is the serial data signal, which shares the same pin with SPI_MOSI. I2S_MCK is the master clock signal. It produces a frequency rate equal to 256 x Fs, and Fs is the audio sampling frequency.

21.9. I2S function overview

21.9.1. I2S audio standards

The I2S audio standard is selected by the I2SSTD bits in the SPI_I2SCTL register. Four audio standards are supported, including I2S Phillips standard, MSB justified standard, LSB justified standard, and PCM standard. All standards except PCM handle audio data time-multiplexed on two channels (the left channel and the right channel). For these standards, the I2S_WS signal indicates the channel side. For PCM standard, the I2S_WS signal indicates frame synchronization information.

The data length and the channel length are configured by the DTLEN bits and CHLEN bit in the SPI_I2SCTL register. Since the channel length must be greater than or equal to the data length, four packet types are available. They are 16-bit data packed in 16-bit frame, 16-bit data packed in 32-bit frame, 24-bit data packed in 32-bit frame, and 32-bit data packed in 32-bit frame. The data buffer for transmission and reception is 16-bit wide. In the case that the data length is 24 bits or 32 bits, two write or read operations to or from the SPI_DATA register are needed to complete a frame. In the case that the data length is 16 bits, only one write or read operation to or from the SPI_DATA register is needed to complete a frame. When using 16-bit data packed in 32-bit frame, 16-bit 0 is inserted by hardware automatically to extend the data to 32-bit format.

For all standards and packet types, the most significant bit (MSB) is always sent first. For all standards based on two channels time-multiplexed, the channel left is always sent first followed by the channel right.

I2S Phillips standard

For I2S Phillips standard, I2S_WS and I2S_SD are updated on the falling edge of I2S_CK. The timing diagrams for each configuration are shown below.

Figure 21-11. I2S Phillips standard timing diagram (DTLEN=00, CHLEN=0, CKPL=0)

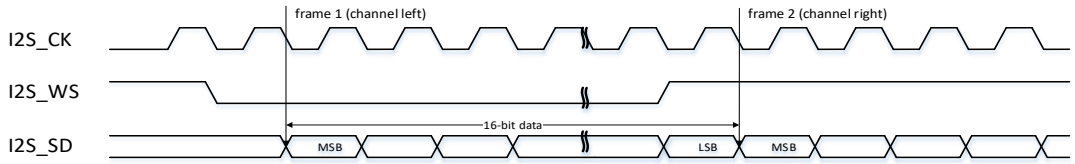


Figure 21-12. I2S Phillips standard timing diagram (DTLEN=00, CHLEN=0, CKPL=1)

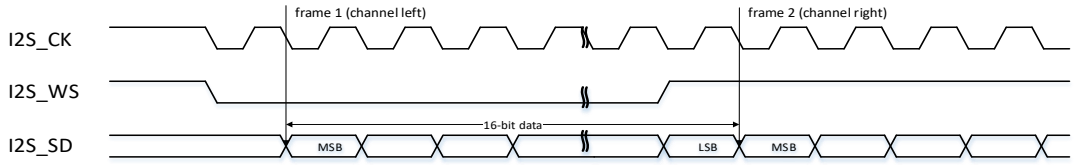

When the packet type is 16-bit data packed in 16-bit frame, only one write or read operation to or from the SPI_DATA register is needed to complete a frame.

Figure 21-13. I2S Phillips standard timing diagram (DTLEN=10, CHLEN=1, CKPL=0)

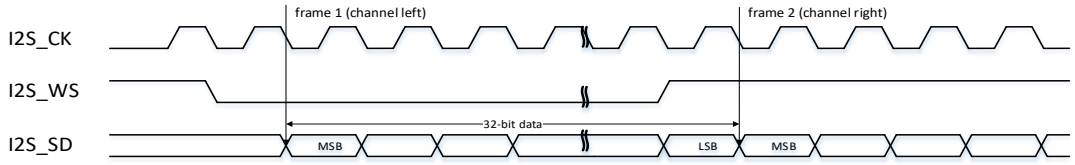

Figure 21-14. I2S Phillips standard timing diagram (DTLEN=10, CHLEN=1, CKPL=1)

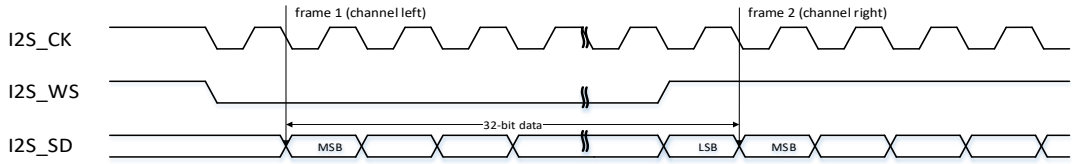

When the packet type is 32-bit data packed in 32-bit frame, two write or read operations to or from the SPI_DATA register are needed to complete a frame. In transmission mode, if a 32-bit data is going to be sent, the first data written to the SPI_DATA register should be the higher 16 bits, and the second one should be the lower 16 bits. In reception mode, if a 32-bit data is received, the first data read from the SPI_DATA register should be higher 16 bits, and the second one should be the lower 16 bits.

Figure 21-15. I2S Phillips standard timing diagram (DTLEN=01, CHLEN=1, CKPL=0)

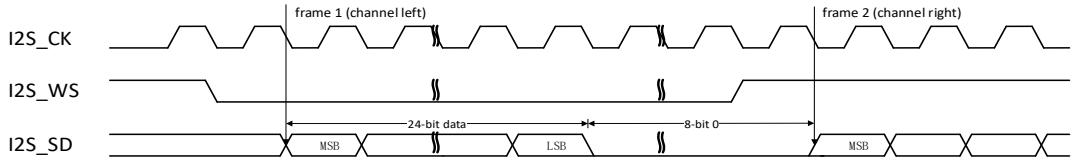

Figure 21-16. I2S Phillips standard timing diagram (DTLEN=01, CHLEN=1, CKPL=1)

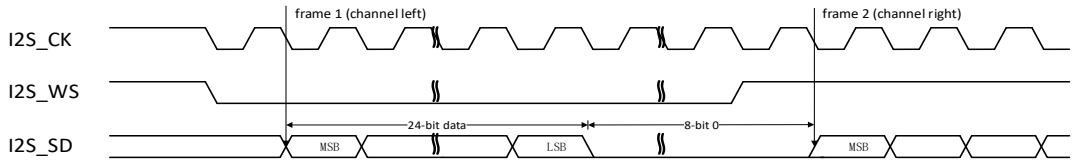

When the packet type is 24-bit data packed in 32-bit frame, two write or read operations to or from the SPI_DATA register are needed to complete a frame. In transmission mode, if a 24-bit data D[23:0] is going to be sent, the first data written to the SPI_DATA register should be the higher 16 bits: D[23:8], and the second one should be a 16-bit data. The higher 8 bits of this 16-bit data should be D[7:0] and the lower 8 bits can be any value. In reception mode, if a 24-bit data D[23:0] is received, the first data read from the SPI_DATA register is D[23:8], and the second one is a 16-bit data. The higher 8 bits of this 16-bit data are D[7:0] and the lower 8 bits are zeros.

Figure 21-17. I2S Phillips standard timing diagram (DTLEN=00, CHLEN=1, CKPL=0)

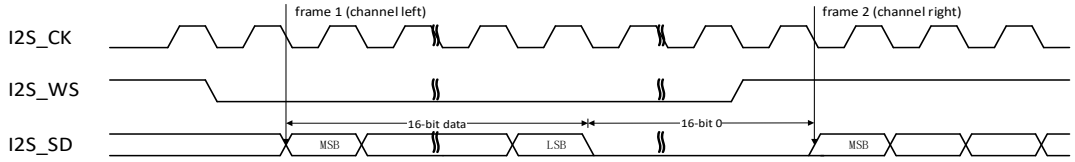

Figure 21-18. I2S Phillips standard timing diagram (DTLEN=00, CHLEN=1, CKPL=1)

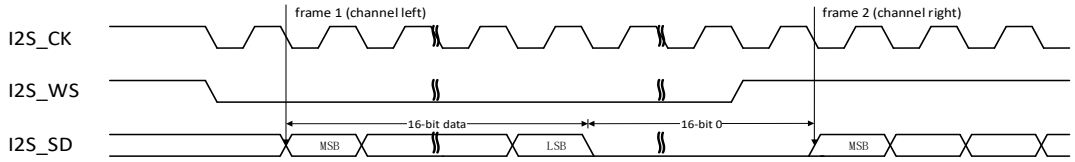

When the packet type is 16-bit data packed in 32-bit frame, only one write or read operation to or from the SPI_DATA register is needed to complete a frame. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

MSB justified standard

For MSB justified standard, I2S_WS and I2S_SD are updated on the falling edge of I2S_CK. The SPI_DATA register is handled in the exactly same way as that for I2S Phillips standard. The timing diagrams for each configuration are shown below.

Figure 21-19. MSB justified standard timing diagram (DTLEN=00, CHLEN=0, CKPL=0)

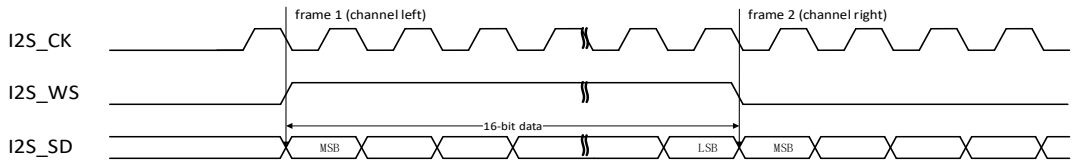

Figure 21-20. MSB justified standard timing diagram (DTLEN=00, CHLEN=0, CKPL=1)

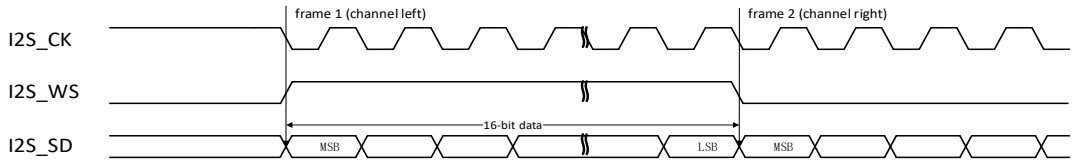

Figure 21-21. MSB justified standard timing diagram (DTLEN=10, CHLEN=1, CKPL=0)

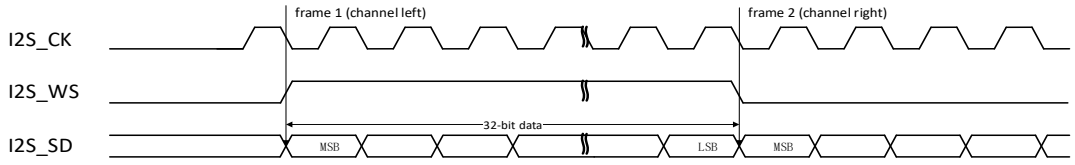

Figure 21-22. MSB justified standard timing diagram (DTLEN=10, CHLEN=1, CKPL=1)

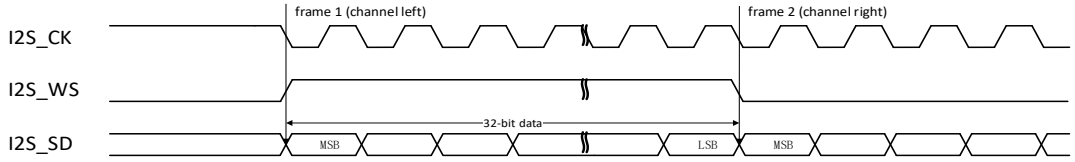

Figure 21-23. MSB justified standard timing diagram (DTLEN=01, CHLEN=1, CKPL=0)

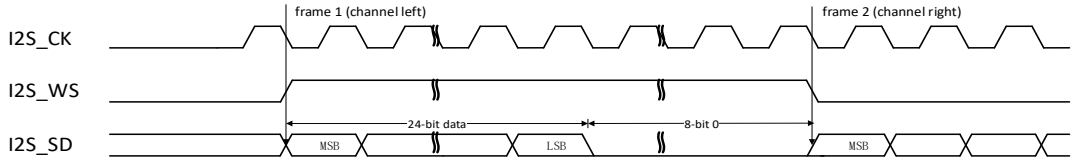

Figure 21-24. MSB justified standard timing diagram (DTLEN=01, CHLEN=1, CKPL=1)

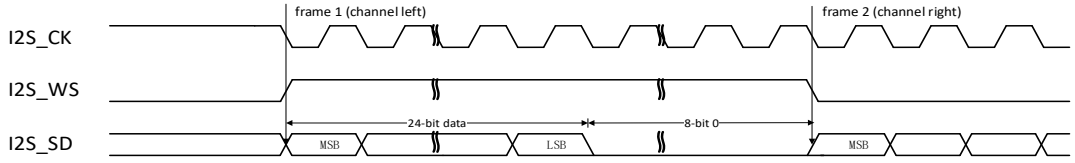

Figure 21-25. MSB justified standard timing diagram (DTLEN=00, CHLEN=1, CKPL=0)

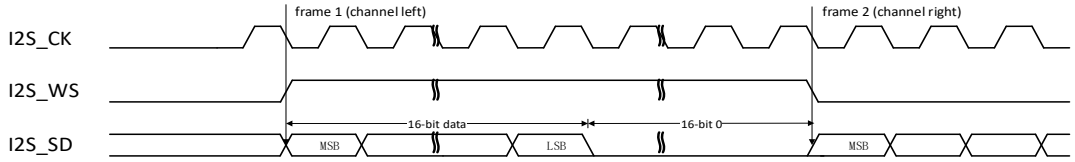

Figure 21-26. MSB justified standard timing diagram (DTLEN=00, CHLEN=1, CKPL=1)

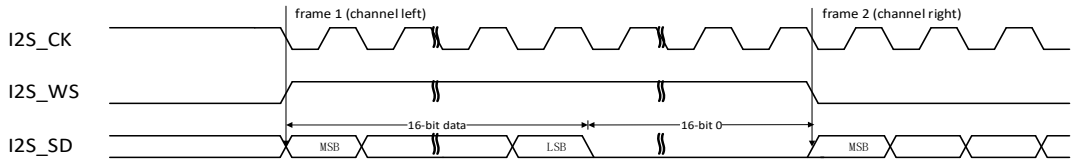

LSB justified standard

For LSB justified standard, I2S_WS and I2S_SD are updated on the falling edge of I2S_CK. In the case that the channel length is equal to the data length, LSB justified standard and MSB justified standard are exactly the same. In the case that the channel length is greater than the data length, the valid data is aligned to LSB for LSB justified standard while the valid data is aligned to MSB for MSB justified standard. The timing diagrams for the cases that the channel length is greater than the data length are shown below.

Figure 21-27. LSB justified standard timing diagram (DTLEN=01, CHLEN=1, CKPL=0)

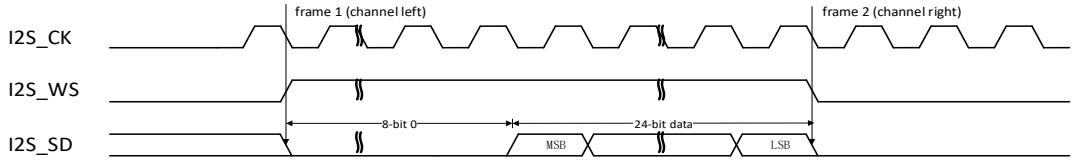

Figure 21-28. LSB justified standard timing diagram (DTLEN=01, CHLEN=1, CKPL=1)

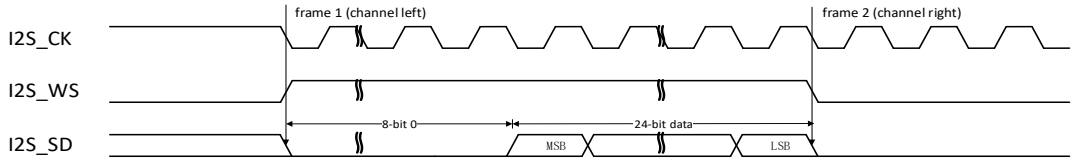

When the packet type is 24-bit data packed in 32-bit frame, two write or read operations to or from the SPI_DATA register are needed to complete a frame. In transmission mode, if a 24-bit data D [23:0] is going to be sent, the first data written to the SPI_DATA register should be a 16-bit data. The higher 8 bits of the 16-bit data can be any value and the lower 8 bits should be D [23:16]. The second data written to the SPI_DATA register should be D [15:0]. In reception mode, if a 24-bit data D [23:0] is received, the first data read from the SPI_DATA register is a 16-bit data. The high 8 bits of this 16-bit data are zeros and the lower 8 bits are D [23:16]. The second data read from the SPI_DATA register is D [15:0].

Figure 21-29. LSB justified standard timing diagram (DTLEN=00, CHLEN=1, CKPL=0)

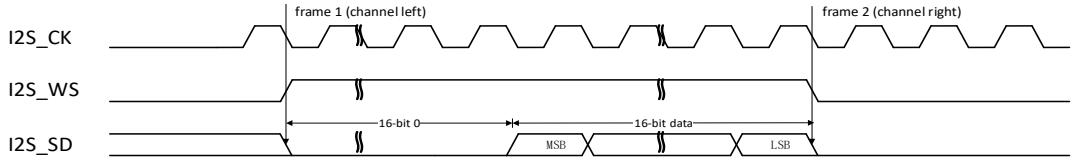

Figure 21-30. LSB justified standard timing diagram (DTLEN=00, CHLEN=1, CKPL=1)

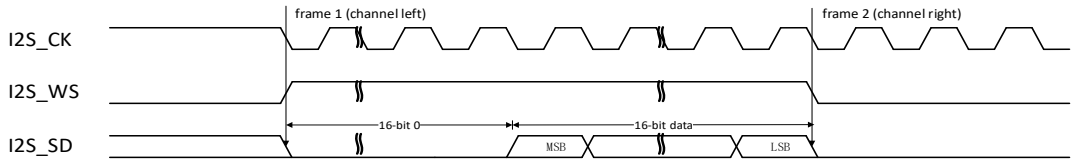

When the packet type is 16-bit data packed in 32-bit frame, only one write or read operation to or from the SPI_DATA register is needed to complete a frame. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

PCM standard

For PCM standard, I2S_WS and I2S_SD are updated on the rising edge of I2S_CK, and the I2S_WS signal indicates frame synchronization information. Both the short frame synchronization mode and the long frame synchronization mode are available and configurable using the PCMSMOD bit in the SPI_I2SCTL register. The SPI_DATA register is handled in the exactly same way as that for I2S Phillips standard. The timing diagrams for each configuration of the short frame synchronization mode are shown below.

Figure 21-31. PCM standard short frame synchronization mode timing diagram (DTLEN=00, CHLEN=0, CKPL=0)

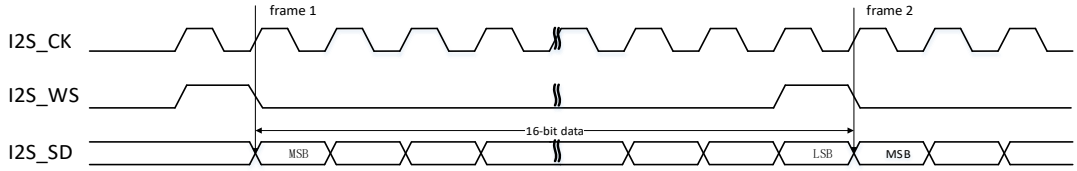

Figure 21-32. PCM standard short frame synchronization mode timing diagram (DTLEN=00, CHLEN=0, CKPL=1)

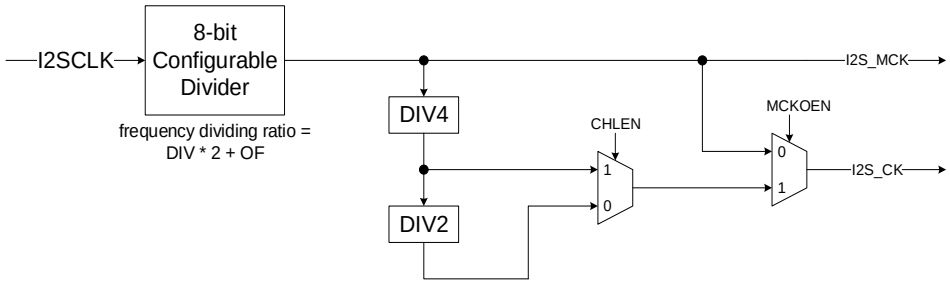
21.9.2. I2S clock

Figure 21-47. Block diagram of I2S clock generator



The block diagram of I2S clock generator is shown as ***Figure 21-47. Block diagram of I2S clock generator***. The I2S interface clocks are configured by the DIV bits, the OF bit, the MCKOEN bit in the SPI_I2SPSC register and the CHLEN bit in the SPI_I2SCTL register. The I2S bitrate can be calculated by the formulas shown in ***Table 21-5. I2S bitrate calculation formulas.***

Table 21-5. I2S bitrate calculation formulas

MCKOEN	CHLEN	Formula
0	0	I2SCLK / (DIV * 2 + OF)
0	1	I2SCLK / (DIV * 2 + OF)
1	0	I2SCLK / (8 * (DIV * 2 + OF))
1	1	I2SCLK / (4 * (DIV * 2 + OF))

The relationship between audio sampling frequency (Fs) and I2S bitrate is defined by the following formula:

Fs = I2S bitrate / (number of bits per channel * number of channels)

So, in order to get the desired audio sampling frequency, the clock generator needs to be configured according to the formulas listed in ***Table 21-6. Audio sampling frequency calculation formulas.***

Table 21-6. Audio sampling frequency calculation formulas

MCKOEN	CHLEN	Formula
0	0	I2SCLK / (32 * (DIV * 2 + OF))
0	1	I2SCLK / (64 * (DIV * 2 + OF))
1	0	I2SCLK / (256 * (DIV * 2 + OF))
1	1	I2SCLK / (256 * (DIV * 2 + OF))

The source of I2S clock can be either from PLLI2S or an external I2S_CKIN pin, and this is programmable in RCU. Software should carefully calculate the factor of I2S and PLLI2S to get the most accurate audio sampling frequency. If PLLI2S cannot meet the application's precision demand, an external precise I2S clock can be imported from I2S_CKIN pin.

21.9.3. Operation

Operation modes

The operation mode is selected by the I2SOPMOD bits in the SPI_I2SCTL register. There are four available operation modes, including master transmission mode, master reception mode, slave transmission mode, and slave reception mode. The direction of I2S interface signals for each operation mode is shown in the ***Table 21-7. Direction of I2S interface signals for each operation mode.***

Table 21-7. Direction of I2S interface signals for each operation mode

Operation mode	I2S_MCK	I2S_CK	I2S_WS	I2S_SD
Master transmission	output or NU(1)	output	output	output
Master reception	output or NU(1)	output	output	input
Slave transmission	input or NU(1)	input	input	output
Slave reception	input or NU(1)	input	input	input

1. NU means the pin is not used by I2S and can be used by other functions.

I2S initialization sequence

I2S initialization sequence contains five steps shown below. In order to initialize I2S working in master mode, all the five steps should be done. In order to initialize I2S working in slave

mode, only step 2, step 3, step 4 and step 5 should be done.

- Step 1: Configure the DIV [7:0] bits, the OF bit, and the MCKOEN bit in the SPI_I2SPSC register, in order to define the I2S bitrate and whether I2S_MCK needs to be provided or not.
- Step 2: Configure the CKPL in the SPI_I2SCTL register, in order to define the idle state clock polarity.
- Step 3: Configure the I2SSEL bit, the I2SSTD [1:0] bits, the PCMSMOD bit, the I2SOPMOD [1:0] bits, the DTLEN [1:0] bits, and the CHLEN bit in the SPI_I2SCTL register, in order to define the I2S feature.
- Step 4: Configure the TBEIE bit, the RBNEIE bit, the ERRIE bit, the DMATEN bit, and the DMAREN bit in the SPI_CTL1 register, in order to select the potential interrupt sources and the DMA capabilities. This step is optional.
- Step 5: Set the I2SEN bit in the SPI_I2SCTL register to enable I2S.

I2S master transmission sequence

The TBE flag is used to control the transmission sequence. As is mentioned before, the TBE flag indicates that the transmit buffer is empty, and an interrupt will be generated if the TBEIE bit in the SPI_CTL1 register is set. At the beginning, the transmit buffer is empty (TBE is high) and no transmission sequence is processing in the shift register. When a half word is written to the SPI_DATA register (TBE goes low), the data is transferred from the transmit buffer to the shift register (TBE goes high) immediately. At the moment, the transmission sequence begins.

The data is parallel loaded into the 16-bit shift register, and shifted out serially to the I2S_SD pin, MSB first. The next data should be written to the SPI_DATA register, when the TBE flag is high. After a write operation to the SPI_DATA register, the TBE flag goes low. When the current transmission finishes, the data in the transmit buffer is loaded into the shift register, and the TBE flag goes back high. Software should write the next audio data into SPI_DATA register before the current data finishes, otherwise, the audio data transmission is not continuous.

For all standards except PCM, the I2SCH flag is used to distinguish the channel side to which the data to transfer belongs. The I2SCH flag is refreshed at the moment when the TBE flag goes high. At the beginning, the I2SCH flag is low, indicating the left channel data should be written to the SPI_DATA register.

In order to switch off I2S, it is mandatory to clear the I2SEN bit after the TBE flag is high and the TRANS flag is low.

I2S master reception sequence

The RBNE flag is used to control the reception sequence. As is mentioned before, the RBNE flag indicates the receive buffer is not empty, and an interrupt will be generated if the RBNEIE

bit in the SPI_CTL1 register is set. The reception sequence begins immediately when the I2SEN bit in the SPI_I2SCTL register is set. At the beginning, the receive buffer is empty (RBNE is low). When a reception sequence finishes, the received data in the shift register is loaded into the receive buffer (RBNE goes high). The data should be read from the SPI_DATA register, when the RBNE flag is high. After a read operation to the SPI_DATA register, the RBNE flag goes low. It is mandatory to read the SPI_DATA register before the end of the next reception. Otherwise, reception overrun error occurs. The RXORERR flag is set and an interrupt may be generated if the ERRIE bit in the SPI_CTL1 register is set. In this case, it is necessary to switch off and then switch on I2S before resuming the communication.

For all standards except PCM, the I2SCH flag is used to distinguish the channel side to which the received data belongs. The I2SCH flag is refreshed at the moment when the RBNE flag goes high.

Different sequences are used to disable the I2S in different standards, data length and channel length. The sequences for each case are described below.

- 16-bit data packed in 32-bit frame in the LSB justified standard (DTLEN = 00, CHLEN = 1, and I2SSTD = 10)
  1. Wait for the second last RBNE
  2. Then wait 17 I2S CK clock (clock on I2S_CK pin) cycles
  3. Clear the I2SEN bit
- 16-bit data packed in 32-bit frame in the audio standards except the LSB justified standard (DTLEN = 00, CHLEN = 1, and I2SSTD is not equal to 10)
  1. Wait for the last RBNE
  2. Then wait one I2S clock cycle
  3. Clear the I2SEN bit
- For all other cases
  1. Wait for the second last RBNE
  2. Then wait one I2S clock cycle
  3. Clear the I2SEN bit

I2S slave transmission sequence

The transmission sequence in slave mode is similar to that in master mode. The difference between them is described below.

In slave mode, the slave has to be enabled before the external master starts the communication. The transmission sequence begins when the external master sends the clock and when the I2S_WS signal requests the transfer of data. The data has to be written to the SPI_DATA register before the master initiates the communication. Software should write the

next audio data into SPI_DATA register before the current data finishe. Otherwise, transmission underrun error occurs. The TXURERR flag is set and an interrupt may be generated if the ERRIE bit in the SPI_CTL1 register is set. In this case, it is mandatory to switch off and switch on I2S to resume the communication. In slave mode, I2SCH is sensitive to the I2S_WS signal coming from the external master.

In order to switch off I2S, it is mandatory to clear the I2SEN bit after the TBE flag is high and the TRANS flag is low.

I2S slave reception sequence

The reception sequence in slave mode is similar to that in master mode. The difference between them is described below.

In slave mode, the slave has to be enabled before the external master starts the communication. The reception sequence begins when the external master sends the clock and when the I2S_WS signal indicates a start of the data transfer. In slave mode, I2SCH is sensitive to the I2S_WS signal coming from the external master.

In order to switch off I2S, it is mandatory to clear the I2SEN bit immediately after receiving the last RBNE.

21.9.4. DMA function

DMA function is the same as SPI mode. The only difference is that the CRC function is not available in I2S mode.

21.10. I2S interrupts

21.10.1. Status flags

There are four status flags implemented in the SPI_STAT register, including TBE, RBNE, TRANS and I2SCH. The user can use them to fully monitor the state of the I2S bus.

- Transmit buffer empty flag (TBE)

This bit is set when the transmit buffer is empty, the software can write the next data to the transmit buffer by writing the SPI_DATA register.

- Receive buffer not empty flag (RBNE)

This bit is set when receive buffer is not empty, which means that one data is received and stored in the receive buffer, and software can read the data by reading the SPI_DATA register.

- I2S Transmitting On-Going flag (TRANS)

TRANS is a status flag to indicate whether the transfer is on-going or not. It is set and cleared by internal hardware and not controlled by software. This flag doesn’t generate any interrupt.

- I2S channel side flag (I2SCH)

This flag indicates the channel side information of the current transfer and has no meaning in PCM mode. It is updated when TBE rises in transmission mode or RBNE rises in reception mode. This flag doesn't generate any interrupt.

21.10.2. Error conditions

There are two error conditions:

- Transmission Underrun Error Flag (TXURERR)

This condition occurs when the transmit buffer is empty when the valid SCK signal starts in slave transmission mode.

- Reception Overrun Error Flag (RXORERR)

This condition occurs when the receive buffer is full and a newly incoming data has been completely received. When overrun occurs, the data in receive buffer is not updated and the newly incoming data is lost.

I2S interrupt events and corresponding enabled bits are summed up in the ***Table 21-8. I2S interrupt***.

Table 21-8. I2S interrupt

Flag Name	Description	Clear Method	Interrupt Enable bit
TBE	Transmit buffer empty	Write SPI_DATA register	TBEIE
RBNE	Receive buffer not empty	Read SPI_DATA register	RBNEIE
TXURERR	Transmission underrun error	Read SPI_STAT register	ERRIE
RXORERR	Reception overrun error	Read SPI_DATA register and then read SPI_STAT register.	

21.11. Register definition

SPI0 start address: 0x4001 3000

SPI1 start address: 0x4000 3800

SPI2 start address: 0x4000 3C00

21.11.1. Control register 0 (SPI_CTL0)

Address offset: 0x00
Reset value: 0x0000

This register has to be accessed by word (32-bit)
This register has no meaning in I2S mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw

Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15	BDEN	Bidirectional enable 0: 2 line unidirectional transmit mode 1: 1 line bidirectional transmit mode. The information transfers between the MOSI pin in master and the MISO pin in slave.
14	BDOEN	Bidirectional Transmit Output Enable When BDEN is set, this bit determines the direction of transfer. 0: Work in receive-only mode 1: Work in transmit-only mode
13	CRCEN	CRC Calculation Enable 0: CRC calculation is disabled 1: CRC calculation is enabled.
12	CRCNT	CRC Next Transfer 0: Next transfer is Data 1: Next transfer is CRC value (TCR) When the transfer is managed by DMA, CRC value is transferred by hardware. This bit should be cleared. In full-duplex or transmit-only mode, set this bit after the last data is written to

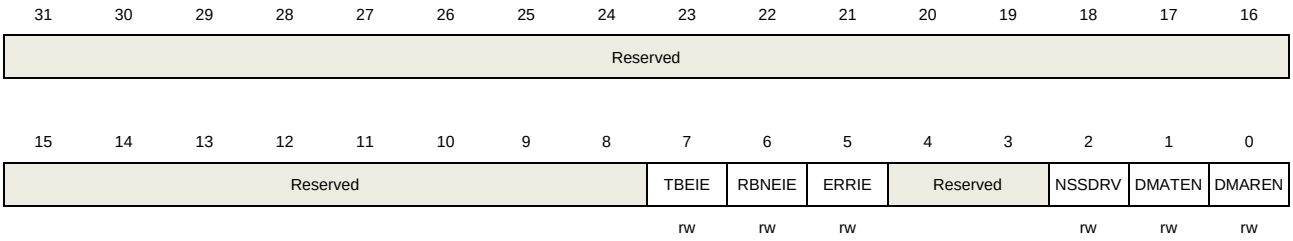
		SPI_DATA register. In receive only mode, set this bit after the second last data is received.
11	FF16	Data frame format 0: 8-bit data frame format 1: 16-bit data frame format
10	RO	Receive only When BDEN is cleared, this bit determines the direction of transfer. 0: Full-duplex 1: Receive-only
9	SWNSSEN	NSS Software Mode Selection 0: NSS hardware mode. The NSS level depends on NSS pin. 1: NSS software mode. The NSS level depends on SWNSS bit.
8	SWNSS	NSS Pin Selection In NSS Software Mode 0: NSS pin is pulled low 1: NSS pin is pulled high This bit has an effect only when the SWNSSEN bit is set.
7	LF	LSB First Mode 0: Transmit MSB first 1: Transmit LSB first
6	SPIEN	SPI Enable 0: SPI peripheral is disabled 1: SPI peripheral is enabled
5:3	PSC[2:0]	Master Clock Prescaler Selection 000: PCLK/2 100: PCLK/32 001: PCLK/4 101: PCLK/64 010: PCLK/8 110: PCLK/128 011: PCLK/16 111: PCLK/256 PCLK means PCLK2 when using SPI0 or PCLK1 when using SPI1 and SPI2.
2	MSTMOD	Master Mode Enable 0: Slave mode 1: Master mode
1	CKPL	Clock Polarity Selection 0: CLK pin is pulled low when SPI is idle 1: CLK pin is pulled high when SPI is idle
0	CKPH	Clock Phase Selection 0: Capture the first data at the first clock transition. 1: Capture the first data at the second clock transition

21.11.2. Control register 1 (SPI_CTL1)

Address offset: 0x04

Reset value: 0x0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value.
7	TBEIE	Transmit Buffer Empty Interrupt Enable 0: TBE interrupt is disabled. 1: TBE interrupt is enabled. An interrupt is generated when the TBE bit is set
6	RBNEIE	Receive Buffer Not Empty Interrupt Enable 0: RBNE interrupt is disabled. 1: RBNE interrupt is enabled. An interrupt is generated when the RBNE bit is set
5	ERRIE	Errors Interrupt Enable. 0: Error interrupt is disabled. 1: Error interrupt is enabled. An interrupt is generated when the CRCERR bit or the CONFERR bit or the RXORERR bit or the TXURERR bit is set.
4:3	Reserved	Must be kept at reset value.
2	NSSDRV	Drive NSS Output 0: NSS output is disabled. 1: NSS output is enabled. If the NSS pin is configured as output, the NSS pin is pulled low in master mode when SPI is enabled. If the NSS pin is configured as input, the NSS pin should be pulled high in master mode, and this bit has no effect.
1	DMATEN	Transmit Buffer DMA Enable 0: Transmit buffer DMA is disabled 1: Transmit buffer DMA is enabled, when the TBE bit in SPI_STAT is set, it will be a DMA request at corresponding DMA channel.
0	DMAREN	Receive Buffer DMA Enable 0: Receive buffer DMA is disabled

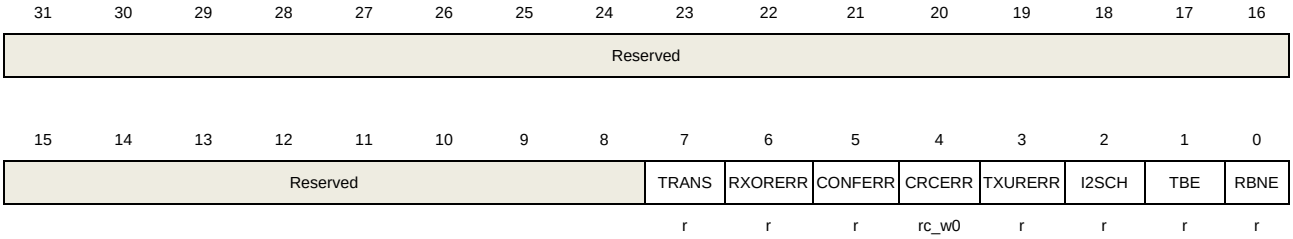
1: Receive buffer DMA is enabled, when the RBNE bit in SPI_STAT is set, it will be a DMA request at corresponding DMA channel.

21.11.3. Status register (SPI_STAT)

Address offset: 0x08

Reset value: 0x0002

This register has to be accessed by word(32-bit).



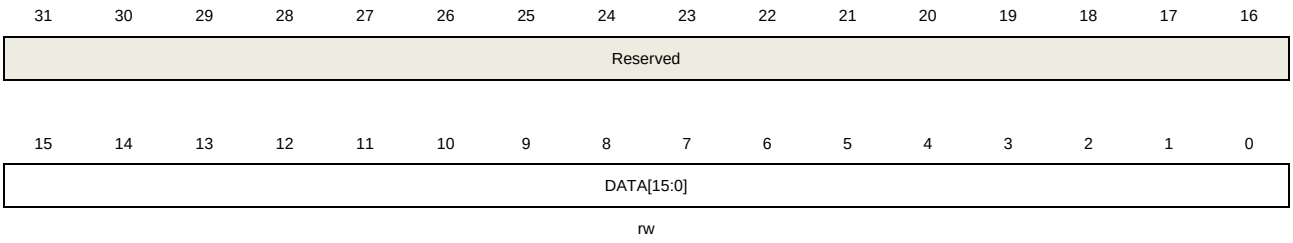
Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value.
7	TRANS	Transmitting On-going Bit 0: SPI or I2S is idle. 1: SPI or I2S is currently transmitting and/or receiving a frame This bit is set and cleared by hardware.
6	RXORERR	Reception Overrun Error Bit 0: No reception overrun error occurs. 1: Reception overrun error occurs. This bit is set by hardware and cleared by a read operation on the SPI_DATA register followed by a read access to the SPI_STAT register.
5	CONFERR	SPI Configuration error Bit 0: No configuration fault occurs 1: Configuration fault occurred. (In master mode, the NSS pin is pulled low in NSS hardware mode or SWNSS bit is low in NSS software mode.) This bit is set by hardware and cleared by a read or write operation on the SPI_STAT register followed by a write access to the SPI_CTL0 register. This bit is not used in I2S mode.
4	CRCERR	SPI CRC Error Bit 0: The SPI_RCRC value is equal to the last received CRC data. 1: The SPI_RCRC value is not equal to the last received CRC data. This bit is set by hardware and is able to be cleared by writing 0. This bit is not used in I2S mode.
3	TXURERR	Transmission underrun error Bit

		0: No transmission underrun error occurs. 1: Transmission underrun error occurs. This bit is set by hardware and cleared by a read operation on the SPI_STAT register. This bit is not used in SPI mode.
2	I2SCH	I2S channel side 0: The next data needs to be transmitted or the data just received belongs to left channel. 1: The next data needs to be transmitted or the data just received belongs to right channel . This bit is set and cleared by hardware. This bit is not used in SPI mode, and has no meaning in the I2S PCM mode.
1	TBE	Transmit Buffer Empty 0: Transmit buffer is not empty 1: Transmit buffer is empty
0	RBNE	Receive Buffer Not Empty 0: Receive buffer is empty 1: Receive buffer is not empty

21.11.4. Data register (SPI_DATA)

Address offset: 0x0C
Reset value: 0x0000

This register has to be accessed by word(32-bit).



Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	DATA[15:0]	Data transfer register. The hardware has two buffers, including transmit buffer and receive buffer. Write data to SPI_DATA will save the data to transmit buffer and read data from SPI_DATA will get the data from receive buffer. When the data frame format is set to 8-bit data, the SPI_DATA [15:8] is forced to 0 and the SPI_DATA [7:0] is used for transmission and reception, transmit buffer and receive buffer are 8-bits. If the Data frame format is set to 16-bit data, the SPI_DATA

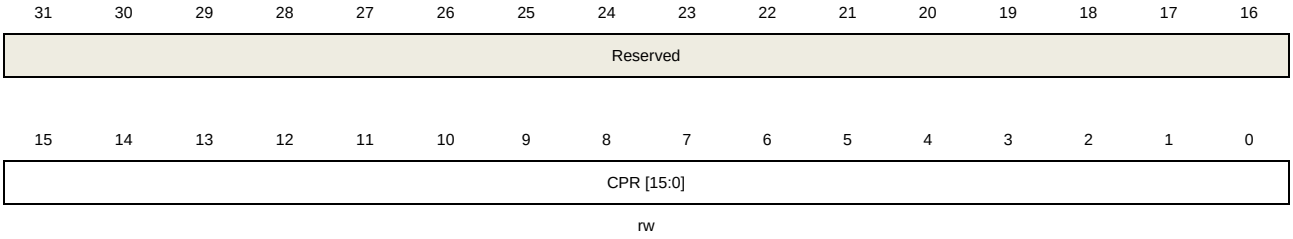
[15:0] is used for transmission and reception, transmit buffer and receive buffer are 16-bit.

21.11.5. CRC polynomial register (SPI_CRCPOLY)

Address offset: 0x10

Reset value: 0x0007

This register has to be accessed by word(32-bit),



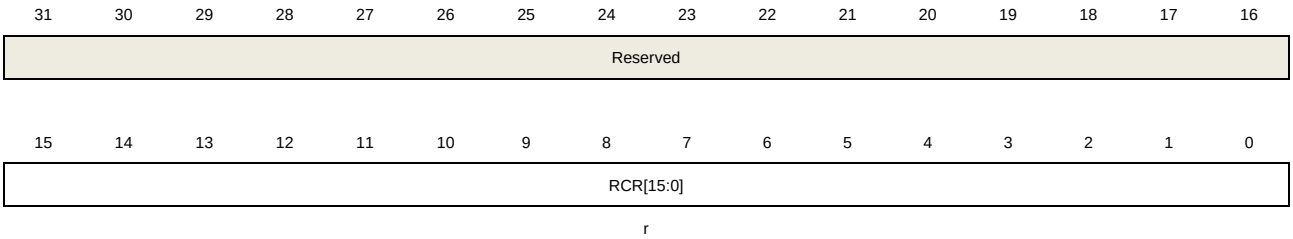
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	CPR[15:0]	CRC polynomial register This register contains the CRC polynomial and it is used for CRC calculation. The default value is 0007h.

21.11.6. RX CRC register (SPI_RCRC)

Address offset: 0x14

Reset value: 0x0000

This register has to be accessed by word(32-bit).



Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	RCR[15:0]	RX CRC register When the CRCEN bit of SPI_CTL0 is set, the hardware computes the CRC value of the received bytes and saves them in RCR register. If the Data frame format is set to 8-bit data, CRC calculation is based on CRC8 standard, and saves the value in

RCR [7:0], when the Data frame format is set to 16-bit data, CRC calculation is based on CRC16 standard, and saves the value in RCR[15:0].

The hardware computes the CRC value after each received bit, when the TRANS is set, a read to this register could return an intermediate value.

This register is reset when the CRCEN bit in SPI_CTL0 register or the SPIxRST bit in RCU reset register is set.

21.11.7. TX CRC register (SPI_TCRC)

Address offset: 0x18

Reset value: 0x0000

This register has to be accessed by word(32-bit).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TCR[15:0]															
r															

Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	TCR[15:0]	TX CRC register When the CRCEN bit of SPI_CTL0 is set, the hardware computes the CRC value of the transmitted bytes and saves them in TCR register. If the Data frame format is set to 8-bit data, CRC calculation is based on CRC8 standard, and saves the value in TCR [7:0], when the Data frame format is set to 16-bit data, CRC calculation is based on CRC16 standard, and saves the value in TCR [15:0]. The hardware computes the CRC value after each transmitted bit, when the TRANS is set, a read to this register could return an intermediate value. The different frame format (LF bit of the SPI_CTL0) will get different CRC value. This register is reset when the CRCEN bit in SPI_CTL0 register or the SPIxRST bit in RCU reset register is set.

21.11.8. I2S control register (SPI_I2SCTL)

Address offset: 0x1C

Reset value: 0x0000

This register has to be accessed by word(32-bit).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

				rw	rw	rw		rw		rw		rw	rw		rw

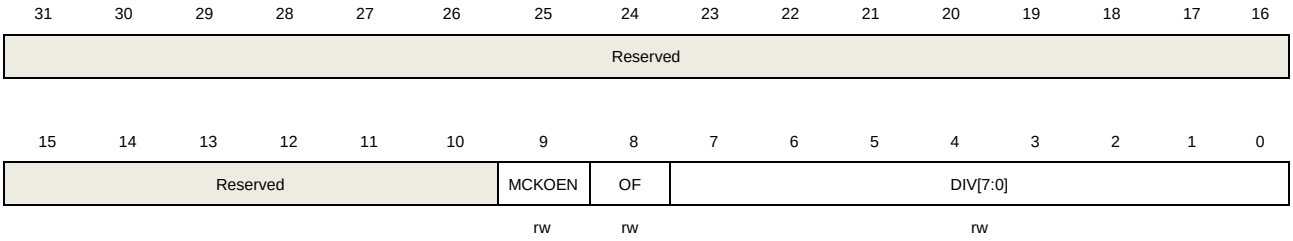
Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11	I2SSEL	I2S mode selection 0: SPI mode 1: I2S mode This bit should be configured when SPI mode or I2S mode is disabled.
10	I2SEN	I2S enable 0: I2S is disabled 1: I2S is enabled This bit is not used in SPI mode.
9:8	I2SOPMOD[1:0]	I2S operation mode 00: Slave transmission mode 01: Slave reception mode 10: Master transmission mode 11: Master reception mode This bit should be configured when I2S mode is disabled. This bit is not used in SPI mode.
7	PCMSMOD	PCM frame synchronization mode 0: Short frame synchronization 1: long frame synchronization This bit has a meaning only when PCM standard is used. This bit should be configured when I2S mode is disabled. This bit is not used in SPI mode.
6	Reserved	Must be kept at reset value
5:4	I2SSTD[1:0]	I2S standard selection 00: I2S Phillips standard 01: MSB justified standard 10: LSB justified standard 11: PCM standard These bits should be configured when I2S mode is disabled. These bits are not used in SPI mode.
3	CKPL	Idle state clock polarity 0: The idle state of I2S_CK is low level 1: The idle state of I2S_CK is high level This bit should be configured when I2S mode is disabled.

		This bit is not used in SPI mode.
2:1	DTLEN[1:0]	Data length 00: 16 bits 01: 24 bits 10: 32 bits 11: Reserved These bits should be configured when I2S mode is disabled. These bits are not used in SPI mode.
0	CHLEN	Channel length 0: 16 bits 1: 32 bits The channel length must be equal to or greater than the data length. This bit should be configured when I2S mode is disabled. This bit is not used in SPI mode.

21.11.9. I2S clock prescaler register (SPI_I2SPSC)

Address offset: 0x20
Reset value: 0x0002

This register has to be accessed by word(32-bit).



Bits	Fields	Descriptions
31:10	Reserved	Must be kept at reset value
9	MCKOEN	I2S_MCK output enable 0: I2S_MCK output is disabled 1: I2S_MCK output is enabled This bit should be configured when I2S mode is disabled. This bit is not used in SPI mode.
8	OF	Odd factor for the prescaler 0: Real divider value is DIV * 2 1: Real divider value is DIV * 2 + 1 This bit should be configured when I2S mode is disabled. This bit is not used in SPI mode.

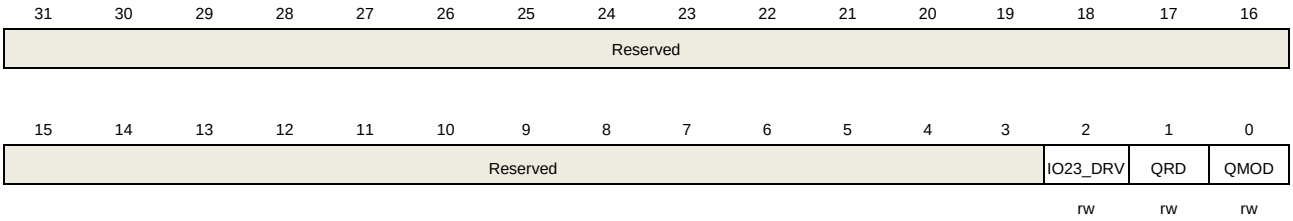
7:0	DIV[7:0]	Dividing factor for the prescaler Real divider value is DIV * 2 + OF. DIV must not be 0. These bits should be configured when I2S mode is disabled. These bits are not used in SPI mode.

21.11.10. Quad-SPI mode control register (SPI_QCTL) of SPI0

Address offset: 0x80

Reset value: 0x0000

This register has to be accessed by word(32-bit).



Bits	Fields	Descriptions
31:3	Reserved	Must be kept at reset value
2	IO23_DRV	Drive IO2 and IO3 enable 0: IO2 and IO3 are not driven in single wire mode 1: IO2 and IO3 are driven to high in single wire mode This bit is only available in SPI0.
1	QRD	Quad-SPI mode read select. 0: SPI is in quad wire write mode 1: SPI is in quad wire read mode This bit should be only be configured when SPI is not busy (TRANS bit cleared) This bit is only available in SPI0.
0	QMOD	Quad-SPI mode enable. 0: SPI is in single wire mode 1: SPI is in Quad-SPI mode This bit should only be configured when SPI is not busy (TRANS bit cleared). This bit is only available in SPI0.

22. Digital camera interface(DCI)

22.1. Overview

DCI is a parallel interface to capture video or picture from a camera. It supports various color space such as YUV/RGB, as well as compression format such as JPEG.

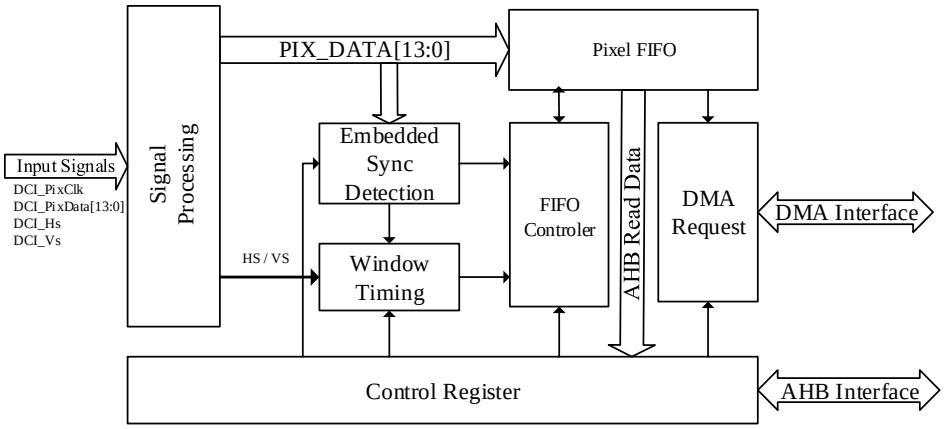
22.2. Characteristics

- Digital video/picture capture
- 8/10/12/14 data width supported
- High transfer efficiency with DMA interface
- Video/picture crop supported
- Various pixel digital encoding formats supported including YCbCr422/RGB565
- JPEG compression format supported
- Hard/embedded synchronous signals supported

22.3. Block diagram

The DCI contains these modules: Signal Processing, Pixel FIFO, FIFO controller, window timing, embedded sync detection, DMA interface and control register.

Figure 22-1. DCI module block diagram



The signal processing module generates useful signals for other internal modules from external input signals. The frequency of HCLK should be 2.5 times higher than DCI_PixClk to ensure the proper operation of signal processing module.

The embedded sync detection module is designed to support embedded synchronization mode. In DCI embedded synchronization mode, video synchronization information is embedded into pixel data and there is no hardware horizontal or vertical synchronization signal (DCI_Hs or DCI_Vs). DCI uses embedded sync detection module to extract synchronization information from pixel data, and then recover horizontal and vertical synchronization signals.

The window timing module performs image cutting function. This module calculates a pixel's position using synchronization signals either from DCI interface or embedded sync detection module and then decides whether this pixel data needs to be received according to the configuration of DCI_CWSPOS and DCI_CWSZ registers.

DCI uses a 4 word (32-bit) FIFO to buffer the received pixel data. If DMA mode is enabled, the DMA interface asserts a DMA request every time the FIFO is not empty. Control register provides register interface between DCI and software.

22.4. Signal description

Table 22-1. PINs used by DCI

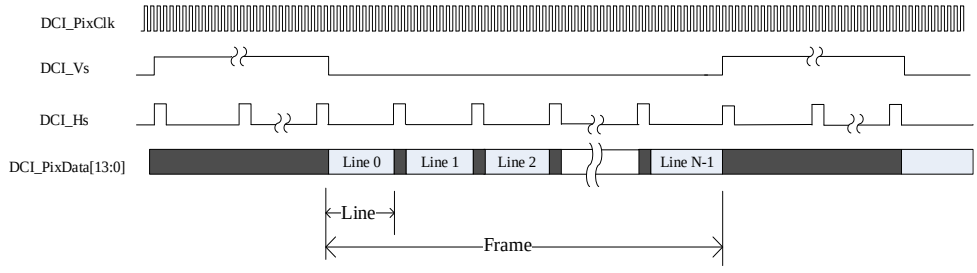
Direction	Name	Width	Description
Input	DCI_PixClk	1	DCI Pixel Clock
Input	DCI_PixData	14	DCI Pixel Data
Input	DCI_Hs	1	DCI Horizontal Synchronization
Input	DCI_Vs	1	DCI Vertical Synchronization

22.5. Function overview

22.5.1. DCI hardware synchronization mode

In DCI hardware synchronization mode (ESM bit in DCI_CTL register is 0), DCI_Hs and DCI_Vs signals are used to indicate the start of a line and a frame. DCI captures pixel data from DCI_PixData[13:0] at rising or falling edge of DCI_PixClk (clock polarity is configured by CKS bit in DCI_CTL).

Figure 22-2. Hardware synchronization mode



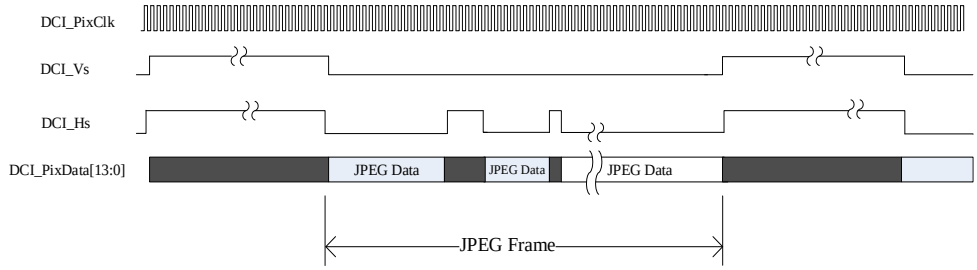
The above figure assumes that the polarities of both DCI_Hs and DCI_Vs are high during

blanking period, so the data on DCI_PixData lines is only valid when both DCI_Hs and DCI_Vs are low.

JPEG mode

DCI supports JPEG video/picture compression format in hardware synchronization mode. In JPEG mode (JM bit in DCI_CTL is set), the DCI_Vs is used to indicate start of a new frame, and DCI_Hs is used as stream data valid signal.

Figure 22-3. Hardware synchronization mode: JPEG format supporting



22.5.2. Embedded synchronization mode

DCI supports embedded synchronization mode. In this mode there are only DCI_PixData and DCI_PixClk signals in DCI interface and the synchronization information is embedded in the pixel data. This mode is enabled by setting ESM bit and clearing JM bit in DCI_CTL register.

In embedded synchronization mode, line and frame synchronization information is encoded into sync code and embedded into the pixel data. There are four kinds of sync code: Line Start(LS), Line End(LE), Frame Start(FS) and Frame End(FE). In this mode the data width is forced to 8 and each sync code is composed by 4-byte sequence: FF-00-00-MN, and MN is defined in DCI_SC register. In embedded synchronization mode, the 0xFF and 0x00 should not appear in pixel data to avoid mistake.

In embedded synchronization mode, DCI starts to detect the sync codes after enabled and recover line/frame synchronization information. For example, DCI starts to capture a new frame if it detects a Frame End code and then a Frame Start Code.

When detecting sync code, it is possible to make DCI compare only a few bits of MN byte in FF_00_00_MN sequence by configuring sync code unmask register (DCI_SCUMSK). DCI will only compare bits unmasked by DCI_SCUMSK register. For example: LS in DCI_SC register is A5 and LSM in DCI_SCUMSK is F0, then DCI will only compare the higher 4 bits for LS sync code and thus, FF-00-00-A6 sequence will also be detected as a LS code.

22.5.3. Capture data using snapshot or continuous capture modes

The DCI supports two capture modes: snapshot and continuous capture. Capture mode is configured by SNAP bit in DCI_CTL register.

After correctly configure, enable DCI and set CAP bit in DCI_CTL register, the DCI begins to detect frame start. It begins to capture data once a frame start is detected. In snapshot

mode(SNAP=1), DCI automatically stops capturing and clears the CAP bit after a whole frame is captured completely, while in continuous mode, DCI prepares to capture the next frame. The DCI capture frequency is defined by FR[1:0] bits in continuous mode. For example, if FR[1:0]=00, DCI captures each frame, and if FR[1:0]=01, DCI only captures every alternate frame.

In continuous mode, software may clear the CAP bit any time when DCI is capturing data, but DCI doesn't stop capture immediately. It always stops after a complete frame ends. Software should read back the CAP bit to know whether the DCI stops effectively.

22.5.4. Window function

DCI supports window function which is able to cut a part of image from the captured frame. Window function is enabled by setting WDEN bit in DCI_CTL register and this function is disabled in JPEG mode.

DCI continuously counts and calculates pixels' horizontal and vertical position during capturing, and compares the position and the values in crop window registers (DCI_CWSPOS and DCI_CWSZ), and then discards those pixels outside the crop window and only pushes pixels inside the window into the pixel FIFO.

If a frame ends when the vertical lines size defined in DCI_CWSZ is not reached yet, the end of frame flag will be triggered and DCI stops the capture.

22.5.5. Pixel formats, data padding and DMA

DCI supports various pixel digital encoding formats including YCbCr422/RGB565. However, DCI only receives these pixel data, pads these pixels into a word and push into a pixel FIFO. DCI doesn't perform any pixel format conversion or data processing and doesn't care about the detail of pixel format.

DCI uses a 32-bits width data buffer to transfer between DCI interface and pixel FIFO. These are two padding method in this module: byte padding and half-word padding, depending on the data width of DCI interface. Data width is configured by DCIF[1:0] in DCI_CTL register. The data width is fixed to 8 in JPEG mode and embedded synchronization mode.

The DMA interface sends DMA request when FIFO is not empty.

Byte padding mode

Byte padding mode is used if data width of DCI interface is 8. In byte padding mode four bytes are filled into the 32-bits width data buffer. In Non-JPEG mode, the DCI pushes the 32-bits buffer's data into the pixel FIFO when the buffer is full or meets the end of a line. In JPEG mode, the DCI pushes the 32-bits buffer's data into the pixel FIFO when the buffer is full or meets the end of a frame.

Table 22-2. Memory view in byte padding mode

D3[7:0]	D2[7:0]	D1[7:0]	D0[7:0]
D7[7:0]	D6[7:0]	D5[7:0]	D4[7:0]

Half-word padding mode

Half-word padding is used if data width of DCI interface is configured into 10/12/14. In this mode each pixel data is extended into 16-bits length by filling zero at higher position, so the 32-bits width data buffer is able to hold two pixel data. DCI pushes the data buffer into pixel FIFO each time the buffer is full or line end.

Table 22-3. Memory view in half-word padding mode

2'b00	D1[13:0]	2'b00	D0[13:0]
2'b00	D3[13:0]	2'b00	D2[13:0]
2'b00	D5[13:0]	2'b00	D4[13:0]
2'b00	D7[13:0]	2'b00	D6[13:0]

22.6. Interrupts

There are several status and error flags in DCI, and interrupts may be asserted from these flags. These status and error flags will assert global DCI interrupt if enabled by corresponding bit in DCI_INTEN. These flags are cleared by writing into DCI_INTC register.

Table 22-4. Status/Error flags

Status Flag Name	Description
ELF	End of Line Flag
EFF	End of Frame Flag
OVRF	FIFO Overrun Flag
VSF	Frame VS Blank Flag
ESEF	Embedded Sync Error Flag

22.7. Register definition

DCI start address: 0x5005 0000

22.7.1. Control register (DCI_CTL)

Address offset: 0x00
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

23. TFT-LCD interface (TLI)

23.1. Overview

The TLI (TFT-LCD Interface) module handles the synchronous LCD interface and provides pixel data, clock and timing signals for passive LCD display. It supports a wide variety of displays with fully programmable timing parameters. A built-in DMA engine continuously move data from system memory to TLI and then, output to an external LCD display. Two separate layers are supported in TLI, as well as layer window and blending function.

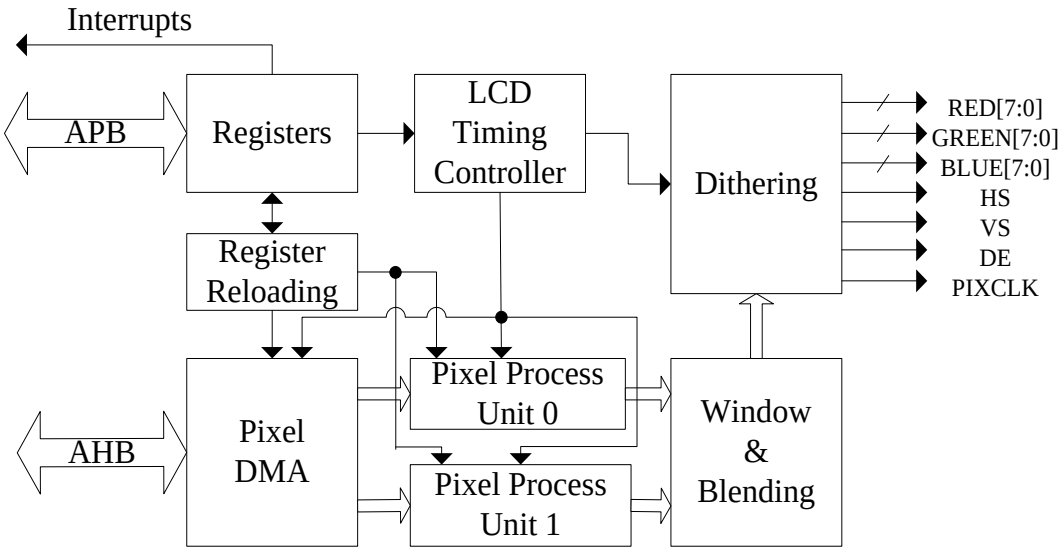
23.2. Characteristics

- Supports up to 24 bits data output per pixel
- Supports up to 800 x 600 resolution
- Timing parameters is fully programmable
- Built-in DMA engine to handle frame data copy
- 2 separate frame layers with window and blending function
- Support various pixel formats: ARGB8888, RGB888, RGB565, etc
- Support CLUT (Color Look-Up-Table) and Color-Keying format
- Dithering operation to low bits of a pixel

23.3. Block diagram

Figure below shows the block diagram of the TLI module. There are three clock domains in TLI. The register works in APB clock and is visited by system APB bus. The Pixel DMA module works in AHB clock and fetches pixel data from system memory using AHB bus. The remaining modules work in TLI clock. The TLI clock is configured by PLLTSEL, PLLTPSC, PLLTMF, PLLTRPSC and TLIPSC, refer to ***PLLT configuration register (RCU_PLLTCFG)*** in RCU module.

Figure 23-1. TLI module block diagram



23.4. Signal description

TLI provides a 24-bit RGB parallel display interface, which is shown in table below.

Table 23-1. Pins of display interface provided by TLI

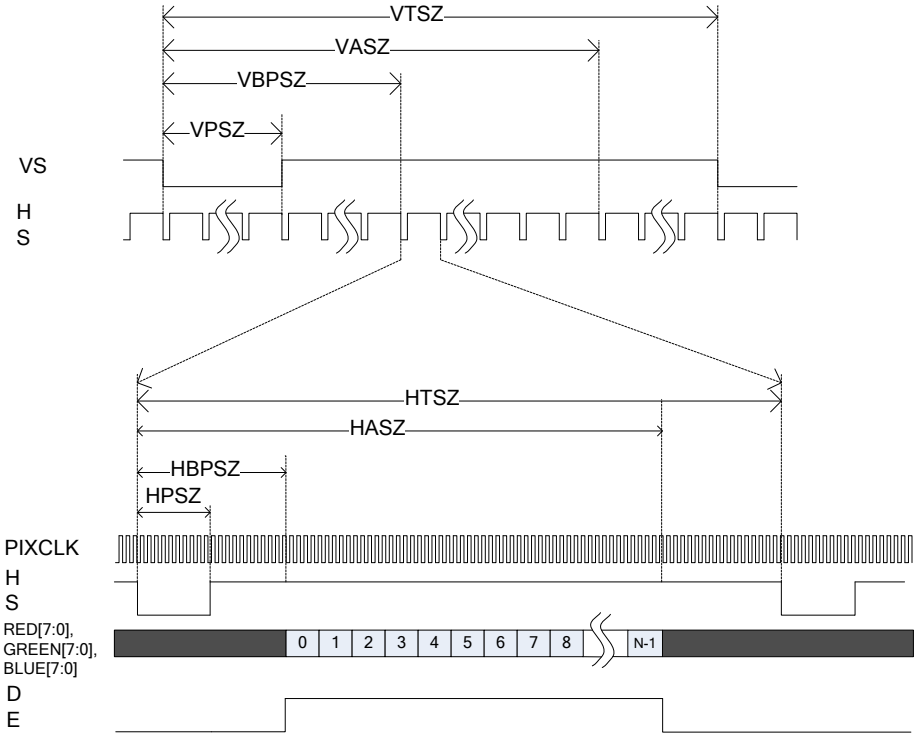
Direction	Name	Width	Description
Output	HS	1	Horizontal Synchronous
Output	VS	1	Vertical Synchronous
Output	DE	1	Data Enable
Output	PIXCLK	1	Pixel Clock
Output	RED[7:0]	8	Pixel Red Data
Output	GREEN[7:0]	8	Pixel Green Data
Output	BLUE[7:0]	8	Pixel Blue Data

23.5. Function overview

23.5.1. LCD display timing

LCD interface is a synchronous data interface with pixel clock, pixel data and horizontal and vertical synchronous signals. The figure below shows the signal timing of HS and VS for a whole frame. The timing parameters are configured in TLI_SPSZ, TLI_BPSZ, TLI_ASZ and TLI_TSZ registers. The timing values in these registers assume that the position of the first point is (0, 0).

Figure 23-2. Display timing diagram



23.5.2. Pixel DMA function

Following the configuration of register module, the Pixel DMA reads pixel data from memory to the pixel buffer in internal PPU (Pixel Process Unit) continuously.

After enabled, the Pixel DMA begins to fetch pixel data from system and push these data into the pixel buffer in PPU as long as the pixel buffer is not full.

TLI supports 2 separate frame layers and each layer has a separate frame buffer address in system. The Pixel DMA has only one AHB access interface, so it will perform round-robin arbitration between the 2 layers during pixels fetching, if both layers are enabled.

FBADD in TLI_LxFBADDR register define the frame buffer address or fetching address of each layer.

FLL in TLI_LxFLLEN defines the line length in bytes of a frame. If the length of a frame line in bytes is N, program FLL with N+3.

There may be some spacing between two frame lines in system memory and the spacing information is defined by STDOFF in TLI_LxFLLEN register. For example if the address of the first pixel in a frame line is M, and the address of the first pixel in the next frame line will be M+STDOFF. If there is no memory spacing between frame lines, just program STDOFF with FLL-3.

FTLN in TLI_LxFTLN register defines the number of lines in a frame.

23.5.3. Pixel formats

The Pixel DMA pushes pixel data into PPU in word format and PPU (Pixel Process Unit) is responsible for converting various pixel formats into an internal ARGB8888 format. TLI supports up to eight pixel formats as shown in the table below. The PPF[2:0] in TLI_LxPPF register defines the pixel format.

ARGB8888 format needs 8-bits data in each channel (Alpha, Red, Green and Blue), while ARGB1555 and ARGB4444 formats have fewer bits than 8 in some channels. PPU converts these formats into ARGB8888 by filling LSBs with MSBs for each channel. When processing RGB888 and RGB565 formats, PPU assumes that Alpha=255 and also fill filling LSBs with MSBs if the channel bit number less than 8.

AL88, AL44 and L8 formats are LUT (Look-Up-Table) formats. In these channels, L is the address of the look-up table. TLI has 2 internal look-up tables: one for each layer. The internal look-up table size is 256x24 bits (256 entries and each entry stores a 24-bits RGB value). When processing LUT format pixel, PPU reads out an entry from the look-up table and uses this entry as the RGB value. Because the address of look-up table is 8-bit, PPU also fill LSBs with MSBs if L channel has bits less than 8. The entries in the look-up tables are uninitialized after reset, so the application should initialize the look-up table with proper value using TLI_LxLUT register before display a look-up table format layer. The TLI_LxLUT is a write-only register and a write operation to this register will write an entry to the look-up table.

Each layer is able to be configured into color keying mode. The register TLI_LxCKEY defines a RGB value. When color keying mode is enabled for a layer, PPU will compare each RGB value of each pixel in this layer with the TLI_LxCKEY and force the pixel's ARGB value to 0 if the value matches.

Table 23-2. Supported pixel formats

PPF[2:0]	Pixel Format
000	ARGB8888
001	RGB888
010	RGB565
011	ARGB1555
100	ARGB4444
111	AL88
101	L8
110	AL44

23.5.4. Layer window and blending function

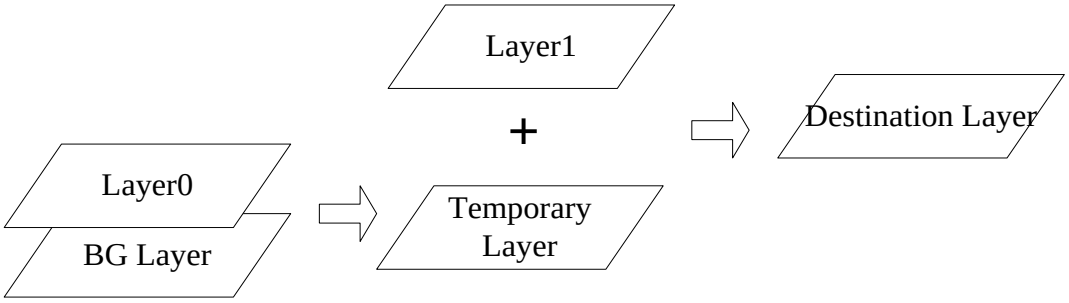
TLI supports window function for each layer and blending function between two layers. TLI first perform window operation to each layer and then blend two layers into a frame.

The window function defines a display window, and each layer has separate window parameters defined by TLI_LxHPOS and TLI_LxVPOS registers. These window parameters

define a window inside the layer. The pixel inside the window will keep its original value, while the pixel outside will be replaced with a default pixel defined in TLI_LxDC register.

The blending units first blends Layer0 and BG Layer into a temporary layer, and then blends Layer1 and the temporary layer into destination layer. BG Layer's ARGB value is defined TLI_BGC register. If a layer is disabled, blending function uses the layer's default color.

Figure 23-3. Block diagram of Blending



Blending formula

The general blending formula is:

$$BC = BF_1 \times C + BF_2 \times C_s \quad (23\text{-}1)$$

- BC is blended color
- BF_1 is alpha calculation Factor 1 of Blending Method
- C is Current layer color
- BF_2 is alpha calculation Factor 2 of Blending Method
- C_s is subjacent layers blended color

The blend factor of current pixel is either normalization Pixel Alpha x normalization Specified Alpha or normalization Specified Alpha which is decided by register configuration.

23.5.5. Layer configuration reload

As is described above, each layer has its own frame buffer, pixel format, window, default color configuration registers and each register has a shadow register. A shadow register shares the same address with the real register. Each time when the application writes to a layer-related register address, the corresponding shadow registers is updated immediately, while the real register will not change until a reload operation and only the real register has effect to the TLI function.

There are two methods for application to trigger a reload operation: request reload and frame blank reload. For request reload mode, then TLI begins to load the shadow registers into real registers immediately after application set RQR bit in TLI_RL register. For frame blank reload

mode, after application set FBR bit in TLI_RL register, the TLI waits for a frame vertical blanking and load the shadow registers. In both modes, hardware automatically clears the RQR or FBR bit after successfully reload.

23.5.6. Dithering function

The dithering module adds a 2-bit pseudo-random value to each pixel channel. This function is able to make the image smoother when 18-bits interface is used to display a 24-bit data. Application may switch on this function using DFEN bit in TLI_CTL register.

23.5.7. Interrupt

There are several status and error flags in TLI, and interrupt may be asserted from these flags. The status flags will assert global interrupt, while the error flags will assert error interrupt.

Table 23-3. Status flags

Status Flag Name	Description
LMF	Line Mark Flag
LCRF	Layer Configuration Reloaded Flag

Table 23-4. Error flags

Error Flag Name	Description
TEF	Transaction Error Flag
FEF	FIFO Error Flag

23.6. Register definition

TLI start address: 0x4001 6800

23.6.1. Synchronous pulse size register (TLI_SPSZ)

Address offset: 0x08
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved				HPSZ[11:0]											
				rw

Bits	Fields	Descriptions
31:28	Reserved	Must keep the reset value
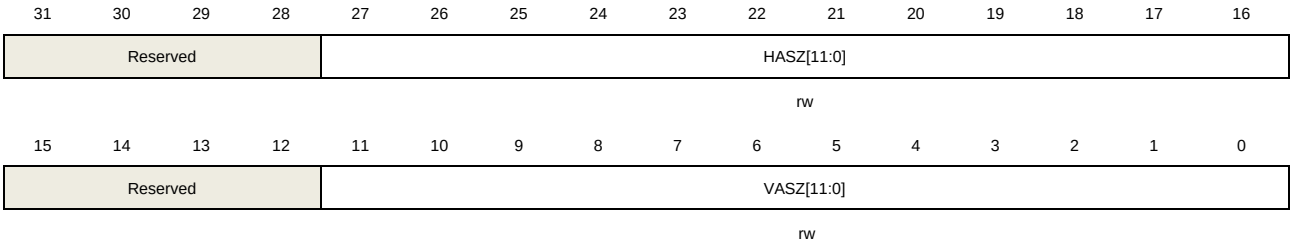
27:16	HBPSZ[11:0]	Size of the horizontal back porch plus synchronous pulse The HBPSZ value should be configured to the pixels number of horizontal back porch and synchronous pulse minus 1.
15:12	Reserved	Must keep the reset value
11:0	VBPSZ[11:0]	Size of the vertical back porch plus synchronous pulse The VBPSZ value should be configured to the pixels number of vertical back porch and synchronous pulse minus 1.

23.6.3. Active size register (TLI_ASZ)

Address offset: 0x10
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:28	Reserved	Must keep the reset value
27:16	HASZ[11:0]	Size of the horizontal active area width plus back porch and synchronous pulse The HASZ value should be configured to the pixels number of horizontal active area width plus back porch and synchronous pulse minus 1.
15:12	Reserved	Must keep the reset value
11:0	VASZ[11:0]	Size of the vertical active area width plus back porch and synchronous pulse The VASZ value should be configured to the pixels number of vertical active area height plus back porch and synchronous pulse minus 1.

23.6.4. Total size register (TLI_TSZ)

Address offset: 0x14
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

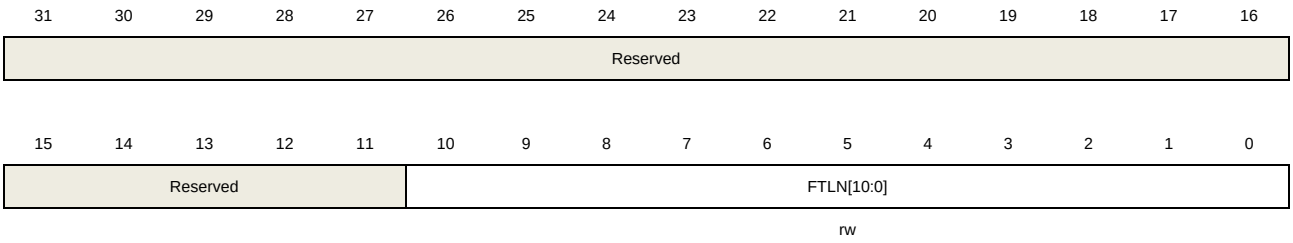
15:14	Reserved	Must keep the reset value
13:0	FLL[13:0]	Frame Line Length This value defines the bytes number of a line plus 3

23.6.24. Layer x frame total line number register (TLI_LxFTLN)

Address offset: 0xB4+0x80*x x=0 or 1
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)

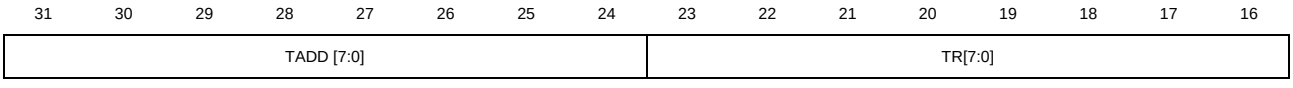


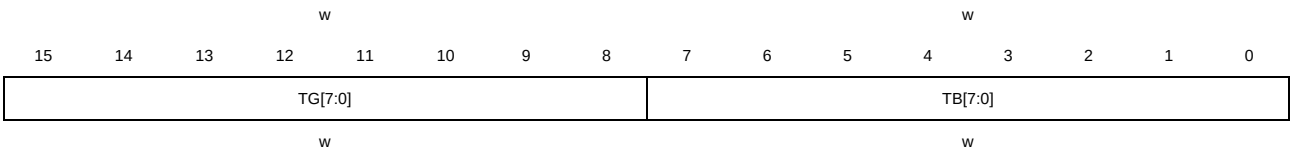
Bits	Fields	Descriptions
31:11	Reserved	Must keep the reset value
10:0	FTLN[10:0]	Frame Total Line Number This value defines the line number in a frame

23.6.25. Layer x look up table register (TLI_LxLUT)

Address offset: 0xC4+0x80*x x=0 or 1
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)





Bits	Fields	Descriptions
31:24	TADD[7:0]	Look Up Table Write Address The entry at this address in LUT will be updated with the value of RED, GREEN and BLUE written
23:16	TR [7:0]	Red Channel of a LUT entry
15:8	TG[7:0]	Green Channel of a LUT entry
7:0	TB [7:0]	Blue Channel of a LUT entry

24. Secure digital input/output interface (SDIO)

24.1. Overview

The secure digital input/output interface (SDIO) defines the SD, SD I/O, MMC and CE-ATA card host interface, which provides command/data transfer between the AHB system bus and SD memory cards, SD I/O cards, Multimedia Card (MMC) and CE-ATA devices.

The supported SD memory card and SD I/O card system specifications are defined in the SD card Association website at ***www.sdcard.org***.

The supported Multimedia Card system specifications are defined through the Multimedia Card Association website at ***www.jedec.org***, published by the JEDEC SOLID STATE TECHNOLOGY ASSOCIATION.

The supported CE-ATA system specifications are defined through the CE-ATA workgroup website at ***www.ce-ata.org***.

24.2. Characteristics

The SDIO features include the following:

- **MMC:** Full support for Multimedia Card System Specification Version 4.2(and previous versions) Card and three different data bus modes: 1-bit (default), 4-bit and 8-bit.
- **SD Card:** Full support for *SD Memory Card Specifications Version 2.0.*
- **SD I/O:** Full support for *SD I/O Card Specification Version 2.0* card and two different data bus modes: 1-bit (default) and 4-bit.
- **CE-ATA:** Full compliance with *CE-ATA digital protocol Version 1.1.*
- 48MHz data transfer frequency and 8-bit data transfer mode.
- Interrupt and DMA request to processor.
- Completion Signal enable and disable feature (CE-ATA).

Note: SDIO supports only one SD, SD I/O, MMC4.2 card or CE-ATA device at any one time and a stack of MMC 4.1 or previous.

24.3. SDIO bus topology

After a power-on reset, the host must initialize the card by a special message-based bus protocol.

Each message is represented by one of the following tokens:

Command: a command is a token which starts an operation. A command is sent from the

host to a card. A command is transferred serially on the CMD line.

Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Data: data can be transferred from the card to the host or vice versa. Data is transferred via the data lines. The number of data lines used for the data transfer can be 1(DAT0), 4(DAT0-DAT3) or 8(DAT0-DAT7).

The structure of commands, responses and data blocks is described in ***Card function*** . One data transfer is a bus operation.

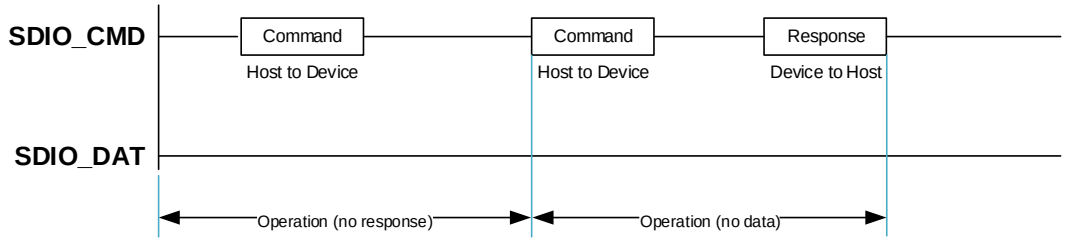
There are different types of operations. Addressed operations always contain a command and a response token. In addition, some operations have a data token; the others transfer their information directly within the command or response structure. In this case no data token is present in an operation. The bits on the DAT0-DAT7 and CMD lines are transferred synchronous to the host clock.

Two types of data transfer commands are defined:

- Stream commands: These commands initiate a continuous data stream; they are terminated only when a stop command follows on the CMD line. This mode reduces the command overhead to an absolute minimum (only MMC supports).
- Block-oriented commands: These commands send a data block successfully by CRC bits. Both read and write operations allow either single or multiple block transmission. A multiple block transmission is terminated when a stop command follows on the CMD line similarly to the sequential read.

The basic transaction on the bus is the command/response transaction (refer to ***Figure 24-1 SDIO "no response" and "no data" operations***). This type of bus transaction transfers their information directly within the command or response structure. In addition, some operations have a data token. Data transfers to/from the Card/Device are done in blocks.

Figure 24-1 SDIO "no response" and "no data" operations



Note that the Multiple Block operation mode is faster than Single Block operation. A multiple block transmission is terminated when a stop command follows on the CMD line. Data transfer can be configured by the host to use single or multiple data lines. ***Figure 24-2. SDIO multiple blocks read operation*** is the multiple block read operation and ***Figure 24-3. SDIO multiple blocks write operation*** is the multiple block write operation. The block write operation uses a simple busy signal of the write operation duration on the data (DAT0) line. CE-ATA device

has an optional busy before it is ready to receive the data.

Figure 24-2. SDIO multiple blocks read operation

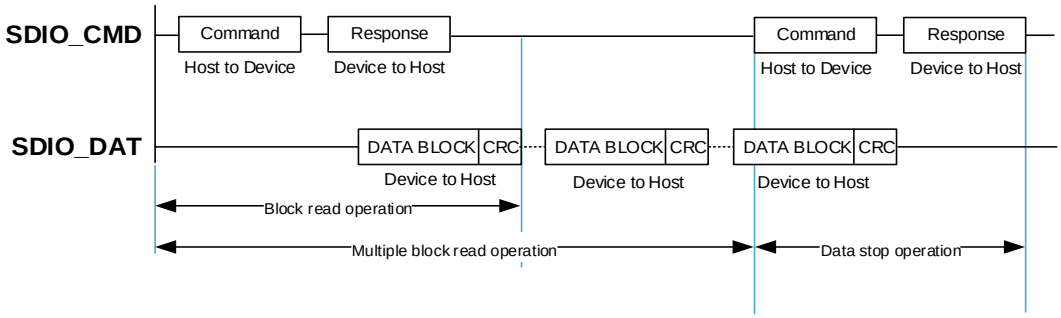


Figure 24-3. SDIO multiple blocks write operation

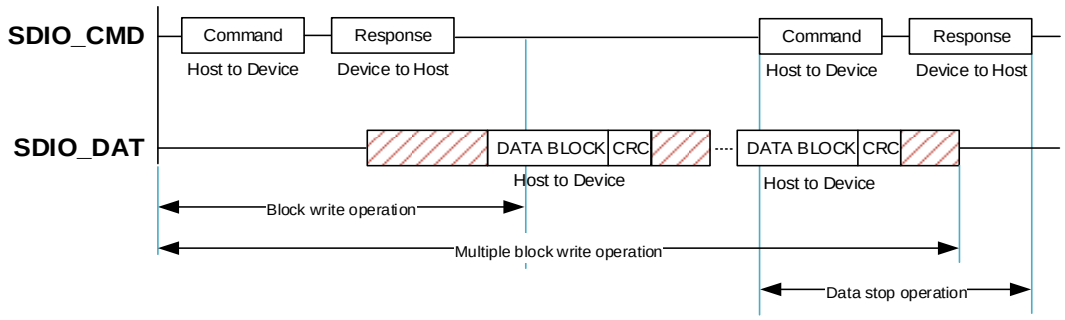

Data transfers to/from SD memory cards, SD I/O cards (both IO only card and combo card) and CE-ATA device are done in data blocks. Data transfers to/from MMC are done in data blocks or streams. ***Figure 24-4. SDIO sequential read operation*** and ***Figure 24-5. SDIO sequential write operation*** are the stream read and write operation.

Figure 24-4. SDIO sequential read operation

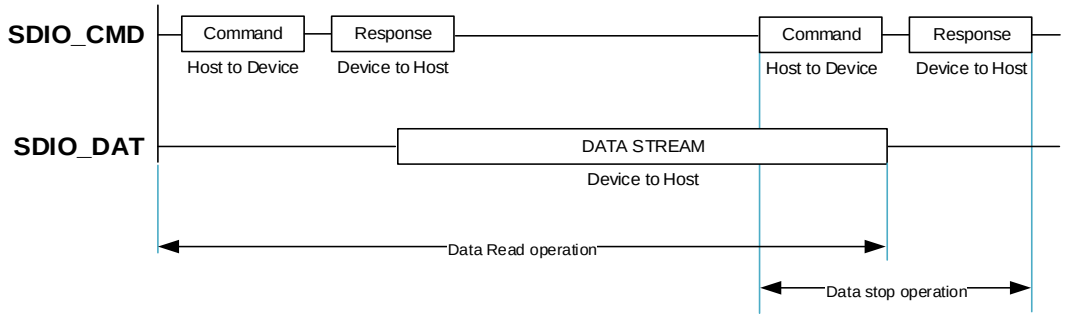

Figure 24-5. SDIO sequential write operation

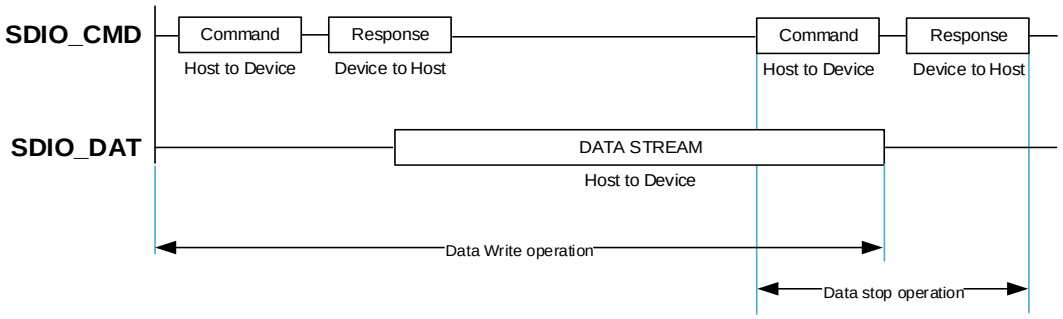
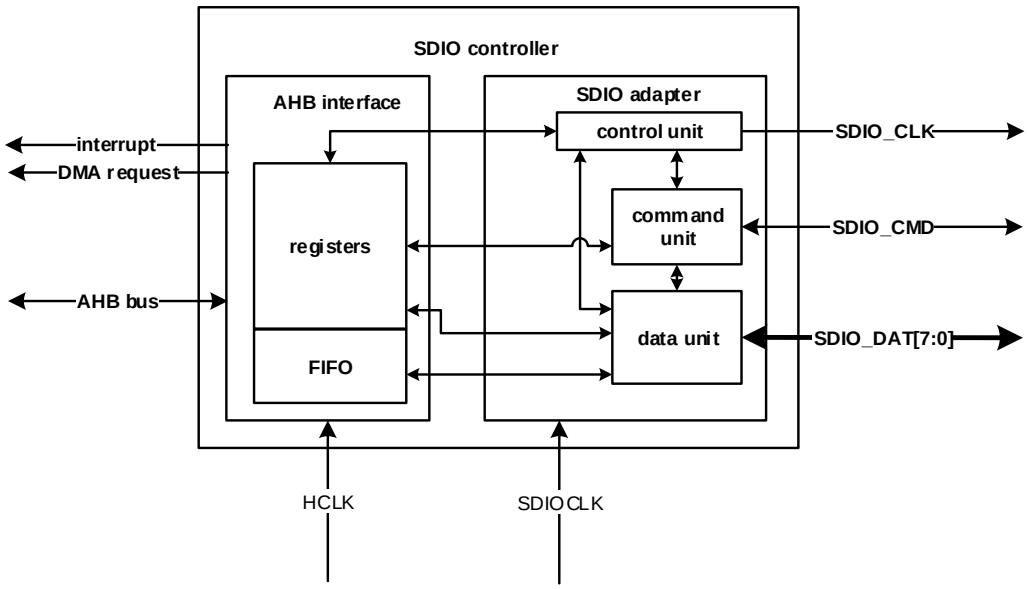


24.4. SDIO function overview

The following figure shows the SDIO structure. There have two main parts:

- The SDIO adapter block consists of control unit which manage clock, command unit which manage command transfer, data unit which manage data transfer.
- The AHB interface block contains access registers by AHB bus, contains FIFO unit which is data FIFO used for data transfer, and generating interrupt and DMA request signals.

Figure 24-6. SDIO block diagram



24.4.1. SDIO adapter

The SDIO adapter contains control unit, command unit and data unit, and generates signals to cards. The signals are descript bellow:

SDIO_CLK: The SDIO_CLK is the clock provided to the card. Each cycle of this signal directs a one bit transfer on the command line (SDIO_CMD) and on all the data lines (SDIO_DAT).

The SDIO_CLK frequency can vary between 0 MHz and 20 MHz for a Multimedia Card V3.31, between 0 and 48 MHz for a Multimedia Card V4.2, or between 0 and 25 MHz for an SD/SD I/O card.

The SDIO uses two clock signals: SDIO adapter clock (SDIOCLK = HCLK) and AHB bus clock (HCLK)

SDIO_CMD: This signal is a bidirectional command channel used for card initialization and transfer of commands. Commands are sent from the SDIO controller to the card and responses are sent from the card to the host. The CMD signal has two operation modes: open-drain for initialization (only for MMC3.31 or previous), and push-pull for command transfer (SD/SD I/O card MMC4.2 use push-pull drivers also for initialization).

SDIO_DAT[7:0]: These are bidirectional data channels. The DAT signals operate in push-pull mode. Only the card or the host is driving these signals at a time. By default, after power up or reset, only DAT0 is used for data transfer. A wider data bus can be configured for data transfer, using either DAT0-DAT3 or DAT0-DAT7 (just for MMC4.2), by the SDIO controller. The SDIO includes internal pull-ups for data lines DAT1-DAT7. Right after entering to the 4-bit mode the card disconnects the internal pull-ups of lines DAT1 and DAT2 (DAT3 internal pull-up is left connected due to the SPI mode CS usage). Correspondingly right after entering to the 8-bit mode the card disconnects the internal pull-ups of lines DAT1, DAT2 and DAT4-DAT7.

Table 24-1. SDIO I/O definitions

Pin function	Direction	Description
SDIO_CLK	O	SD/SD I/O /MMC clock
SDIO_CMD	I/O	Command input/output
SDIO_DAT[7:0]	I/O	Data input/output for data lines DAT[7:0]

The SDIO adapter is an interface to SD, SD I/O, MMC and CE-ATA. It consists of three subunits:

Control unit

The control unit contains the power management functions and the clock management functions for the memory card clock. The power management is controlled by SDIO_PWRCTL register which implements power off or power on. The power saving mode configured by setting CLKPWRSAV bit in SDIO_CLKCTL register, which implements close the SDIO_CLK when the bus is idle. The clock management generates SDIO_CLK to card. The SDIO_CLK is generated by a divider of SDIOCLK when CLKBYP bit in SDIO_CLKCTL register is 0, or directly SDIOCLK when CLKBYP bit in SDIO_CLKCTL register is 1.

The Hardware clock control is enabled by setting HWCLKEN in SDIO_CLKCTL register. This functionality is used to avoid FIFO underrun and overrun errors, hardware control the SDIO_CLK on/off depending on the system bus is very busy or not. When the FIFO cannot receive or transmit data, the host will stop the SDIO_CLK and freeze SDIO state machines to avoid the corresponded error. Only state machines are frozen, the AHB interface is still alive.

So, the FIFO can access by AHB bus.

Command unit

The command unit implements command transfer to the card. The data transfer flow is controlled by Command State Machine (CSM). After a write operation to SDIO_CMDCTL register and CSMEN in SDIO_CMDCTL register is 1, the command transfer starts. It firstly sends a command to the card. The command contains 48 bits send by SDIO_CMD signal which sends 1 bits to card at one SDIO_CLK. The 48 bits command contains 1 bit Start bit, 1 bit Transmission bit, 6 bits command index defined by CMDIDX bits in SDIO_CMDCTL register, 32 bits argument defined in SDIO_CMDAGMT register, 7 bits CRC, and 1 bit end bit. Then receive response from the card if CMDRESP in SDIO_CMDCTL register is not 0b00/0b10. There are short response which have 48 bits or long response which have 136 bits. The response stores in SDIO_RESP0 - SDIO_RESP3 registers. The command unit also generates the command status flags defined in SDIO_STAT register.

Command state machine

CS_Idle	After reset, ready to send command.	
1.CSM enabled and WAITDEND enabled	→	CS_Pend
2.CSM enabled and WAITDEND disabled	→	CS_Send
3.CSM disabled	→	CS_Idle
Note: The state machine remains in the Idle state for at least eight SDIO_CLK periods to meet the N_{CC} and N_{RC} timing constraints. N_{CC} is the minimum delay between two host commands, and N_{RC} is the minimum delay between the host command and the response.		

CS_Pend	Waits for the end of data transfer.	
1.The data transfer complete	→	CS_Send
2.CSM disabled	→	CS_Idle

CS_Send	Sending the command.	
1.The command transmitted has response	→	CS_Wait
2.The command transmitted doesn’t have response	→	CS_Idle
3.CSM disabled	→	CS_Idle

CS_Wait	Wait for the start bit of the response.	
1.Receive the response(detected the start bit)	→	CS_Receive
2.Timeout is reached without receiving the response	→	CS_Idle
3.CSM disabled	→	CS_Idle
Note: The command timeout has a fixed value of 64 SDIO_CLK clock periods.		

CS_Receive	Receive the response and check the CRC.

1.Response Received in CE-ATA mode and interrupt disabled and wait for CE-ATA Command Completion signal enabled	→	CS_Waitcompl
2.Response Received in CE-ATA mode and interrupt disabled and wait for CE-ATA Command Completion signal disabled	→	CS_Pend
3.CSM disabled	→	CS_Idle
4.Response received	→	CS_Idle
5.Command CRC failed	→	CS_Idle

CS_Waitcompl	Wait for the Command Completion signal.	
1.CE-ATA Command Completion signal received	→	CS_Idle
2.CSM disabled	→	CS_Idle
3.Command CRC failed	→	CS_Idle

Data unit

The data unit performs data transfers to and from cards. The data transfer uses SDIO_DAT[7:0] signals when 8-bits data width (BUSMODE bits in SDIO_CLKCTL register is 0b10), use SDIO_DAT[3:0] signals when 4-bits data width (BUSMODE bits in SDIO_CLKCTL register is 0b01), or SDIO_DAT[0] signal when 1-bit data width (BUSMODE bits in SDIO_CLKCTL register is 0b00). The data transfer flow is controlled by Date State Machine (DSM). After a write operation to SDIO_DATACTL register and DATAEN in SDIO_DATACTL register is 1, the data transfer starts. It sends data to card when DATADIR in SDIO_DATACTL register is 0, or receive data from card when DATADIR in SDIO_DATACTL register is 1. The data unit also generates the data status flags defined in SDIO_STAT register.

Data state machine

DS_Idle	The data unit is inactive, waiting for send and receive.	
1.DSM enabled and data transfer direction is from host to card	→	DS_WaitS
2.DSM enabled and data transfer direction is from card to host	→	DS_WaitR
3.DSM enabled and Read Wait Started and SD I/O mode enabled	→	DS_Readwait

DS_WaitS	Wait until the data FIFO empty flag is deasserted or data transfer ended.	
1.Data transfer ended	→	DS_Idle
2.DSM disabled	→	DS_Idle
3.Data FIFO empty flag is deasserted	→	DS_Send

DS_Send	Transmit data to the card.	
1.Data block transmitted	→	DS_Busy
2.DSM disabled	→	DS_Idle
3.Data FIFO underrun error occurs	→	DS_Idle
4. Internal CRC error	→	DS_Idle

DS_Busy	Waits for the CRC status flag.	
1.Receive a positive CRC status	→	DS_WaitS
2.Receive a negative CRC status	→	DS_Idle
3.DSM disabled	→	DS_Idle
4.Timeout occurs	→	DS_Idle
Note: The data timeout programmed in the data timer register (SDIO_DATATO).		

DS_WaitR	Wait for the start bit of the receive data.	
1.Data receive ended	→	DS_Idle
2.DSM disabled	→	DS_Idle
3.Data timeout reached	→	DS_Idle
4.Receives a start bit before timeout	→	DS_Receive
Note: The data timeout programmed in the data timer register (SDIO_DATATO).		

DS_Receive	Receive data from the card and write it to the data FIFO.	
1.Data block received	→	DS_WaitR
2.Data transfer ended	→	DS_WaitR
3.Data FIFO overrun error occurs	→	DS_Idle
4.Data received and Read Wait Started and SD I/O mode enabled	→	DS_Readwait
5.DSM disabled or CRC fails	→	DS_Idle

DS_Readwait	Wait for the read wait stop command.	
1.ReadWait stop enabled	→	DS_WaitR
2.DSM disabled	→	DS_Idle

24.4.2. AHB interface

The AHB interface implements access to SDIO registers, data FIFO and generates interrupt and DMA request. It includes a data FIFO unit, registers unit, and the interrupt / DMA logic.

The interrupt logic generates interrupt when at least one of the selected status flags is high. An interrupt enable register is provided to allow the logic to generate a corresponding interrupt.

The DMA interface provides a method for fast data transfers between the SDIO data FIFO and memory. The following example describes how to implement this method:

1. Complete the card identification process

2. Increase the SDIO_CLK frequency

3. Send CMD7 to select the card and configure the bus width

4. Configure the DMA1 as follows:

Enable DMA1 controller and clear any pending interrupts. Configure the DMA1_Channel3 source address register with the memory base address and DMA1_Channel3 destination address register with the SDIO_FIFO register address. Program DMA1_Channel3 control register (memory increment, not peripheral increment, peripheral and source width is word size, M2M disable).

5. Write block to card as follows:

Write the data size in bytes in the SDIO_DATALEN register. Write the block size in bytes (BLKSZ) in the SDIO_DATACTL register; the host sends data in blocks of size BLKSZ each. Program SDIO_CMDAGMT register with the data address, where data should be written. Program the SDIO command control register (SDIO_CMDCTL): CMDIDX with 24, CMDRESP with 1 (SDIO card host waits for a short response); CSMEN with '1' (enable to send a command). Other fields are their reset value.

When the CMDRECV flag is set, program the SDIO data control register (SDIO_DATACTL): DATAEN with 1 (enable to send data); DATADIR with 0 (from controller to card); TRANSMOD with 0 (block data transfer); DMAEN with 1 (DMA enabled); BLKSZ with 0x9 (512 bytes). Other bits don't care.

Wait for DTBLKEND flag is set. Check that no channels are still enabled by polling the DMA Interrupt Flag register.

It consists the following subunits:

Register unit

The register unit which contains all system registers generates the signals to control the communication between the controller and card.

Data FIFO

The data FIFO unit has a data buffer, used as transmit and receive FIFO. The FIFO contains a 32-bit wide, 32-word deep data buffer. The transmit FIFO is used when write data to card and TXRUN in SDIO_STAT register is 1. The data to be transferred is written to transmit FIFO by AHB bus, the data unit in SDIO adapter read data from transmit FIFO, and then send the data to card. The receive FIFO is used when read data from card and RXRUN in SDIO_STAT register is 1. The data to be transferred is read from the card and then write to receive FIFO. The data in receive FIFO is read to AHB bus when needed. This unit also generates FIFO flags in SDIO_STAT registers.

24.5. Card function overview

24.5.1. Card registers

Within the card interface registers are defined: OCR, CID, CSD, EXT_CSD, RCA, DSR and SCR. These can be accessed only by corresponding commands. The OCR, CID, CSD and SCR registers carry the card/content specific information, while the RCA and DSR registers are configuration registers storing actual configuration parameters. The EXT_CSD register carries both, card specific information and actual configuration parameters. For specific information, please refer to the relevant specifications.

OCR register: The 32-bit operation conditions register (OCR) stores the V_{DD} voltage profile of the card and the access mode indication (MMC). In addition, this register includes a status information bit. This status bit is set if the card power up procedure has been finished. The register is a little different between MMC and SD card. The host can use CMD1 (MMC), ACMD41 (SD memory), CMD5 (SD I/O) to get the content of this register.

CID register: The Card Identification (CID) register is 128 bits wide. It contains the card identification information used during the card identification phase. Every individual Read/Write (RW) card shall have a unique identification number. The host can use CMD2 and CMD10 to get the content of this register.

CSD register: The Card-Specific Data register provides information regarding access to the card contents. The CSD defines the data format, error correction type, maximum data access time, data transfer speed, whether the DSR register can be used, etc. The programmable part of the register can be changed by CMD27. The host can use CMD9 to get the content of this register.

Extended CSD Register: Just MMC4.2 has this register. The Extended CSD register defines the card properties and selected modes. It is 512 bytes long. The most significant 320 bytes are the Properties segment, which defines the card capabilities and cannot be modified by the host. The lower 192 bytes are the Modes segment, which defines the configuration the card is working in. These modes can be changed by the host by means of the SWITCH command. The host can use CMD8 (just MMC supports this command) to get the content of this register.

RCA register: The writable 16-bit relative card address register carries the card address that is published by the card during the card identification. This address is used for the addressed host-card communication after the card identification procedure. The host can use CMD3 to ask the card to publish a new relative address (RCA).

Note: The default value of the RCA register is 0x0001(MMC) or 0x0000(SD/SD I/O). The default value is reserved to set all cards into the Stand-by State with CMD7.

DSR register (Optional): The 16-bit driver stage register can be optionally used to improve the bus performance for extended operating conditions (depending on parameters like bus

length, transfer rate or number of cards). The CSD register carries the information about the DSR register usage. The default value of the DSR register is 0x404. The host can use CMD4 to get the content of this register.

SCR register: Just SD/SD I/O (if has memory port) have this register. In addition to the CSD register, there is another configuration register named SD CARD Configuration Register (SCR), which is only for SD card. SCR provides information on the SD Memory Card's special features that were configured into the given card. The size of SCR register is 64 bits. This register shall be set in the factory by the SD Memory Card manufacturer. The host can use ACMD51 to get the content of this register.

24.5.2. Commands

Commands types

There are four kinds of commands defined to control the Card:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on DAT
- Addressed (point-to-point) data transfer commands (adtc), data transfer on DAT

Command format

All commands have a fixed code length of 48 bits, as show in ***Figure 24-7. Command Token Format***, needing a transmission time of 1.92μs (25 MHz) 0.96μs (50 MHz) and 0.92us (52 MHz).

Figure 24-7. Command Token Format

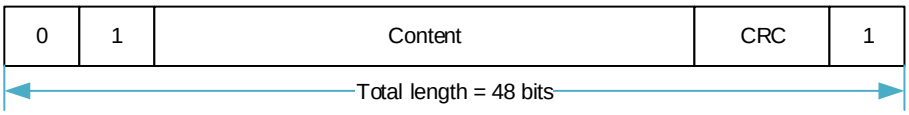


Table 24-2. Command format

Bit position	47	46	[45:40]	[39:8]	[7:1]	0
Width	1	1	6	32	7	1
Value	'0'	'1'	x	x	x	'1'
Description	start bit	transmission bit	command index	argument	CRC7	end bit

A command always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (host = 1). The next 6 bits indicate the index of the command, this value being interpreted as a binary coded number (between 0 and 63). Some commands need an argument (e.g. an address), which is coded by 32 bits. A value denoted by 'x' in the table above indicates this variable is dependent on the command. All commands are protected by

a CRC7. Every command code word is terminated by the end bit (always 1).

Command classes

The command set of the Card system is divided into several classes (See ***Table 24-3. Card command classes (CCCs)***). Each class supports a set of card functionalities. ***Table 24-3. Card command classes (CCCs)*** determines the setting of CCC from the card supported commands.

For SD cards, Class 0, 2, 4, 5 and 8 are mandatory and shall be supported. Class 7 except CMD40 is mandatory for SDHC. The other classes are optional. The supported Card Command Classes (CCC) are coded as a parameter in the card specific data (CSD) register of each card, providing the host with information on how to access the card.

For MMC cards, Class 0 is mandatory and shall be supported. The other classes are either mandatory only for specific card types or optional. By using different classes, several configurations can be chosen (e.g. a block writable card or a stream readable card). The supported Card Command Classes (CCC) are coded as a parameter in the card specific data (CSD) register of each card, providing the host with information on how to access the card.

For CE-ATA device, the device shall support the MMC commands required to achieve the transfer state during device initialization. Other interface configuration settings, such as bus width, may require additional MMC commands also be supported. See the MMC reference. CE-ATA makes use of the following MMC commands: CMD0 - GO_IDLE_STATE, CMD12 - STOP_TRANSMISSION, CMD39 - FAST_IO, CMD60 - RW_MULTIPLE_REGISTER, CMD61 - RW_MULTIPLE_BLOCK. GO_IDLE_STATE (CMD0), STOP_TRANSMISSION (CMD12), and FAST_IO (CMD39) are as defined in the MMC reference. RW_MULTIPLE_REGISTER (CMD60) and RW_MULTIPLE_BLOCK (CMD61) are MMC commands defined by CE-ATA.

ACMD51	M									+			

Note: 1.CMD1, CMD11, CMD14, CMD19, CMD20, CMD23, CMD26, CMD39 and CMD40 are only available for MMC. CMD5, CMD32-34, CMD50, CMD52, CMD53, CMD57 and ACMDx are only available for SD card. CMD60, CMD61 are only available for CE-ATA device.

2. All the ACMDs shall be preceded with APP_CMD command (CMD55).

3. CMD8 has different meaning for MMC and SD memory.

Detailed command description

The following tables describe in detail all bus commands. The responses R1-R7 are defined in ***Responses***. The registers CID, CSD and DSR are described in ***Card registers***. The card shall ignore stuff bits and reserved bits in an argument.

Table 24-4. Basic commands (class 0)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all cards to idle state

Cmd index	type	argument	Response format	Abbreviation	Description
CMD1	bc	[31:0] OCR without busy	R3	SEND_OP_COND	Asks the card, in idle state, to send its Operating Conditions Register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks any card to send the CID numbers on the CMD line (any card that is connected to the host will respond)
CMD3	bcr	[31:0] stuff bits	R6	SEND_RELATIVE_ADDR	Ask the card to publish a new relative address (RCA)
CMD4	bc	[31:16] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards
CMD5	bcr	[31:25]reserved bits [24]S18R [23:0] I/O OCR	R4	IO_SEND_OP_COND	Only for I/O cards. It is similar to the operation of ACMD41 for SD memory cards, used to inquire about the voltage range needed by the I/O card.
CMD6	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Only for MMC. Switches the mode of operation of the selected card or modifies the EXT_CSD registers.
CMD7	ac	[31:16] RCA [15:0] stuff bits	R1b	SELECT/DESELECT_CARD	Command toggles a card between the stand-by and transfer states or between the programming and disconnects states. In both cases the card is selected by its own relative address and gets deselected by any other address; address 0 deselects the card.
CMD8	bcr	[31:12]reserved bits [11:8]supply voltage(VHS) [7:0]check pattern	R7	SEND_IF_COND	Sends SD Memory Card interface condition, which includes host supply voltage information and asks the card whether card supports voltage. Reserved bits shall be set to '0'.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	For MMC only. The card sends its EXT_CSD register as a block of data.

Cmd index	type	argument	Response format	Abbreviation	Description
CMD9	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card identification (CID) on CMD the line.
CMD12	ac	[31:0] stuff bits	R1b	STOP TRANSMISSION	Forces the card to stop transmission
CMD13	ac	[31:16] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	adtc	[31:0] stuff bits	R1	BUSTEST_R	A host reads the reversed bus testing data pattern from a card.
CMD15	ac	[31:16] RCA [15:0] reserved bits	-	GO_INACTIVE_ STATE	Sends an addressed card into the Inactive State. This command is used when the host explicitly wants to deactivate a card.
CMD19	adtc	[31:0] stuff bits	R1	BUSTEST_W	A host sends the bus test data pattern to a card.

Table 24-5. Block-Oriented read commands (class 2)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	In the case of a Standard Capacity SD and MMC, this command sets the block length (in bytes) for all following block commands (read, write, lock). Default is 512 Bytes. Set length is valid for memory access commands only if partial block read operation are allowed in CSD. In the case of a High Capacity SD Memory Card, block length set by CMD16 command does not affect the memory read and write commands. Always 512 Bytes fixed block length is used. In both cases, if block length is

Cmd index	type	argument	Response format	Abbreviation	Description
					set larger than 512Bytes, the card sets the BLOCK_LEN_ERROR bit.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	In the case of a Standard Capacity SD and MMC, this command reads a block of the size selected by the SET_BLOCKLEN command. In the case of a High Capacity Card, block length is fixed 512 Bytes regardless of the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a STOP_TRANSMISSION command. Block length is specified the same as READ_SINGLE_BLOCK command.
Note: The transferred data must not cross a physical block boundary, unless READ_BLK_MISALIGN is set in the CSD register					

Table 24-6. Stream read commands (class 1) and stream write commands (class 3)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.
Note: The transferred data must not cross a physical block boundary, unless READ_BLK_MISALIGN is set in the CSD register					

Table 24-7. Block-Oriented write commands (class 4)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	See description in ***Table 24-5. Block-Oriented read commands (class 2)***.
CMD23	ac	[31:16] set to 0 [15:0] number of blocks	R1	SET_BLOCK_ COUNT	Defines the number of blocks which are going to be transferred in the immediately succeeding multiple block read or write command. If the argument is all 0s, the subsequent read/write operation will be open-ended.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	In the case of a Standard Capacity SD, this command writes a block of the size selected by the SET_BLOCKLEN command. In the case of a SDHC, block length is fixed 512 Bytes regardless of the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE _BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows. Block length is specified the same as WRITE_BLOCK command.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.

Cmd index	type	argument	Response format	Abbreviation	Description
Note: 1.The data transferred shall not cross a physical block boundary unless WRITE_BLK_MISALIGN is set in the CSD. In the case that write partial blocks is not supported, then the block length=default block length (given in CSD). 2. Data address is in byte units in a Standard Capacity SD Memory Card and in block (512 Byte) units in a High Capacity SD Memory Card.					

Table 24-8. Erase commands (class 5)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD32	ac	[31:0] data address	R1	ERASE_WR_BLK_START	Sets the address of the first write block to be erased.(SD)
CMD33	ac	[31:0] data address	R1	ERASE_WR_BLK_END	Sets the address of the last write block of the continuous range to be erased.(SD)
CMD35	ac	[31:0]data address	R1	ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.(MMC)
CMD36	ac	[31:0]data address	R1	ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.(MMC)
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erases all previously selected write blocks.
Note: 1.CMD34 and CMD37 are reserved in order to maintain backwards compatibility with older versions of the MMC. 2. Data address is in byte units in a Standard Capacity SD Memory Card and in block (512 Byte) units in a High Capacity SD Memory Card.					

Table 24-9. Block oriented write protection commands (class 6)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE). A High Capacity SD Memory

Cmd index	type	argument	Response format	Abbreviation	Description
					Card does not support this command.
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
Note: 1. High Capacity SD Memory Card does not support these three commands.					

Table 24-10. Lock card (class 7)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD16	ac	[31:0] block length	R1	SET_BLOCK_LEN	See description in ***Table 24-5. Block-Oriented read commands (class 2)***.
CMD42	adtc	[31:0] Reserved bits (Set all 0)	R1	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command. Reserved bits in the argument and in Lock Card Data Structure shall be set to 0.

Table 24-11. Application-specific commands (class 8)

Cmd index	type	argument	Response format	Abbreviation	Description
ACMD41	bcr	[31]reserved bit [30]HCS [29:24]reserved bits [23:0]V_{DD} Voltage Window(OCR[23:0])	R3	SD_SEND_OP_COND	Sends host capacity support information (HCS) and asks the accessed card to send its operating condition register(OCR) content in the response. HCS is effective when card receives SEND_IF_COND command.

Cmd index	type	argument	Response format	Abbreviation	Description
					CCS bit is assigned to OCR[30].
ACMD42	ac	[31:1] stuff bits [0]set_cd	R1	SET_CLR_CARD_DETECT	Connect[1]/Disconnect[0] the 50K pull-up resistor on CD/DAT3 (pin 1) of the card.
ACMD51	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits. [0] RD/WR	R1	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose/application specific command. The host sets RD/WR=1 for reading data from the card and sets to 0 for writing data to the card.
CMD60	adtc	[31] WR [23:18] Address [7:2] Byte Count Other bits are reserved bits.	R1(read)/ R1b(write)	RW_MULTIPLE_REGISTER	Read or write register in address range.
CMD61	adtc	[31] WR [15:0] Data Unit Count Other bits are reserved bits	R1(read)/ R1b(write)	RW_MULTIPLE_BLOCK	Read or write data block in address range.
Note: 1.ACMDx is Application-specific Commands for SD memory. 2. CMD60, CMD61 are Application-specific Commands for CE-ATA device.					

Table 24-12. I/O mode commands (class 9)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD39	ac	[31:16] RCA [15] register write flag	R4	FAST_IO	Used to write and read 8 bit (register) data fields. The command addresses a card

Cmd index	type	argument	Response format	Abbreviation	Description
		[14:8] register address [7:0] register data			and a register and provides the data for writing if the write flag is set. The R4 response contains data read from the addressed register if the write flag is cleared to 0. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode
CMD52	adtc	[31] R/W Flag [30:28] Function Number [27] RAW Flag [26] Stuff Bits [25:9] Register Address [8] Stuff Bits [7:0] Write Data/Stuff Bits	R5	IO_RW_DIRECT	The IO_RW_DIRECT is the simplest means to access a single register within the total 128K of register space in any I/O function, including the common I/O area (CIA). This command reads or writes 1 byte using only 1 command/response pair. A common use is to initialize registers or monitor status values for I/O functions. This command is the fastest means to read or write single I/O registers, as it requires only a single command/response pair.
CMD53	adtc	[31] R/W Flag [30:28] Function Number [27] Block Mode [26] OP code [25:9] Register Address [8:0] Byte/Block Count		IO_RW_EXTENDED	This command allows the reading or writing of a large number of I/O registers with a single command.
Note: 1.CMD39, CMD40 are only for MMC. 2. CMD52, CMD53 are only for SD I/O card.					

Table 24-13. Switch function commands (class 10)

Cmd index	type	argument	Response format	Abbreviation	Description
CMD6	adtc	[31] Mode 0:Check function 1:Switch function [30:24] reserved [23:20] reserved for function group 6 (0h or Fh) [19:16] reserved for function group 5 (0h or Fh) [15:12] reserved for function group 4 (0h or Fh) [11:8] reserved for function group 3 (0h or Fh) [7:4] function group 2 for command system [3:0] function group 1 for access mode	R1	SWITCH_FUNC	Only for SD memory and SD I/O. Checks switchable function (mode 0) and switch card function (mode 1).

24.5.3. Responses

All responses are sent on the CMD line. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type.

Responses types

There are 7 types of responses show as follows.

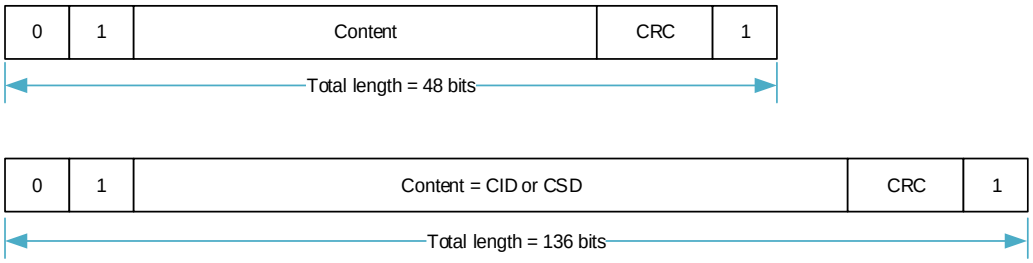
- **R1 / R1b :** normal response command.
- **R2 :** CID, CSD register.
- **R3 :** OCR register.
- **R4 :** Fast I/O.
- **R5 :** Interrupt request.
- **R6 :** Published RCA response.
- **R7 :** Card interface condition.

The SD Memory Card support five types of them, R1 / R1b, R2, R3, R6, R7. And the SD I/O Card and MMC supports additional response types named R4 and R5, but they are not exactly the same for SD I/O Card and MMC.

Responses format

Responses have two formats, as show in ***Figure 24-8. Response Token Format***, all responses are sent on the CMD line. The code length depends on the response type. Except R2 is 136 bits length, others are all 48 bits length.

Figure 24-8. Response Token Format



A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value 'x' in the tables below indicates a variable entry. All responses except for the type R3 are protected by a CRC. Every command code word is terminated by the end bit (always 1).

R1 (normal response command)

Code length is 48 bits. The bits 45:40 indicate the index of the command to be responded to, this value being interpreted as a binary coded number (between 0 and 63). The status of the card is coded in 32 bits. Note that if a data transfer to the card is involved, then a busy signal may appear on the data line after the transmission of each block of data. The host shall check for busy after data block transmission. The card status is described in ***Two status fields of the card***.

Table 24-14. Response R1

Bit position	47	46	[45:40]	[39:8]	[7:1]	0
Width	1	1	6	32	7	1
Value	'0'	'0'	x	x	x	'1'
description	start bit	transmission bit	command index	card status	CRC7	end bit

R1b

R1b is identical to R1 with an optional busy signal transmitted on the data line DAT0. The card may become busy after receiving these commands based on its state prior to the command reception. The Host shall check for busy at the response.

R2 (CID, CSD register)

Code length is 136 bits. The contents of the CID register are sent as a response to the commands CMD2 and CMD10. The contents of the CSD register are sent as a response to CMD9. Only the bits [127..1] of the CID and CSD are transferred, the reserved bit [0] of these

registers is replaced by the end bit of the response.

Table 24-15. Response R2

Bit position	135	134	[133:128]	[127:1]	0
Width	1	1	6	127	1
Value	'0'	'0'	'111111'	x	'1'
description	start bit	transmission bit	reserved	CID or CSD register and internal CRC7	end bit

R3 (OCR register)

Code length is 48 bits. The contents of the OCR register are sent as a response to ACMD41 (SD memory), CMD1 (MMC). The response of different cards may have a little different.

Table 24-16. Response R3

Bit position	47	46	[45:40]	[39:8]	[7:1]	0
Width	1	1	6	32	7	1
Value	'0'	'0'	'111111'	x	'1111111'	'1'
description	start bit	transmission bit	reserved	OCR register	reserved	end bit

R4 (Fast I/O)

For MMC only. Code length is 48 bits. The argument field contains the RCA of the addressed card, the register address to be read out or written to, and its contents. The status bit in the argument is set if the operation was successful.

Table 24-17. Response R4 for MMC

Bit position	47	46	[45:40]	[39:8] Argument field				[7:1]	0
Width	1	1	6	16	1	7	8	7	1
Value	'0'	'0'	'100111'	x	x	x	x	x	'1'
description	start bit	transmission bit	CMD39	RCA [31:16]	status [15]	register address [14:8]	read register contents [7:0]	CRC7	end bit

R4b

For SD I/O only. Code length is 48 bits. The SDIO card receive the CMD5 will respond with a unique SD I/O response R4.

Table 24-18. Response R4 for SD I/O

Bit position	47	46	[45:40]	39	[38:36]	35	[34:32]	31	[30:8]	[7:1]	0
Width	1	1	6	1	3	1	3	1	23	7	1

Value	'0'	'0'	'111111'	x	x	x	'000'	x	x	'1111111'	1
description	start bit	transmission bit	Reserved	C	Number of I/O functions	Memory Present	Stuff Bits	S18A	I/O OCR	Reserved	end bit

R5 (Interrupt request)

For MMC only. Code length is 48 bits. If the response is generated by the host, the RCA field in the argument will be 0x0.

Table 24-19. Response R5 for MMC

Bit position	47	46	[45:40]	[39:8] Argument field		[7:1]	0
Width	1	1	6	16	16	7	1
Value	'0'	'0'	'101000'	x	x	x	'1'
description	start bit	transmission bit	CMD40	RCA [31:16] of winning card or of the host	[15:0] Not defined. May be used for IRQ data	CRC7	end bit

R5b

For SD I/O only. The SDIO card's response to CMD52 and CMD53 is R5. If the communication between the card and host is in the 1-bit or 4-bit SD mode, the response shall be in a 48-bit response (R5).

Table 24-20. Response R5 for SD I/O

Bit position	47	46	[45:40]	[39:24]	[23:16]	[15:8]	[7:1]	0
Width	1	1	6	16	8	8	7	1
Value	'0'	'0'	'11020X'	'0'	x	x	x	'1'
description	start bit	transmission bit	CMD52/53	Stuff Bits	Response Flags	Read or Write Data	CRC7	end bit

R6 (Published RCA response)

Code length is 48 bit. The bits [45:40] indicate the index of the command to be responded to (CMD3). The 16 MSB bits of the argument field are used for the Published RCA number.

Table 24-21. Response R6

Bit position	47	46	[45:40]	[39:8] Argument field		[7:1]	0
Width	1	1	6	16	16	7	1
Value	'0'	'0'	'000011'	x	x	x	'1'
description	start bit	transmission bit	CMD3	New published RCA of the card	card status bits:23,22,19,12:0	CRC7	end bit

R7 (Card interface condition)

For SD memory only. Code length is 48 bits. The card support voltage information is sent by the response of CMD8. Bits 19-16 indicate the voltage range that the card supports. The card that accepted the supplied voltage returns R7 response. In the response, the card echoes back both the voltage range and check pattern set in the argument.

Table 24-22. Response R7

Bit position	47	46	[45:40]	[39:20]	[19:16]	[15:8]	[7:1]	0

description	start bit	transmission bit	CMD8	Reserved bits	Voltage accepted	echo-back of check pattern	CRC7	end bit

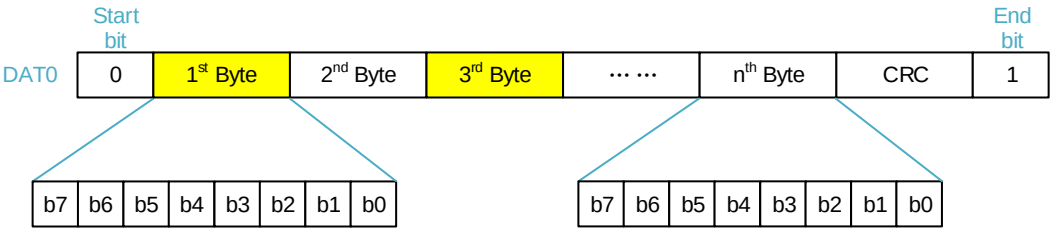
24.5.4. Data packets format

There are 3 data bus mode, 1-bit, 4-bit and 8-bit width. 1-bit mode is mandatory, 4-bit and 8-bit mode is optional. Although using 1-bit mode, DAT3 also need to notify card current working mode is SDIO or SPI, when card reset and initialize.

1-bit data packet format

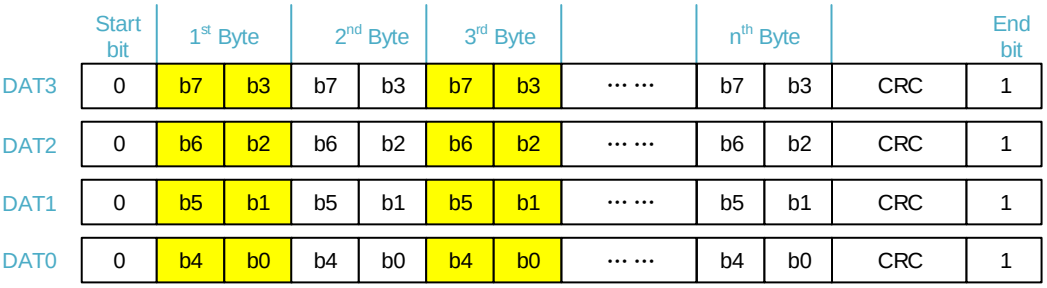
After card reset and initialize, only DAT0 pin is used to transfer data. And other pin can be used freely. ***Figure 24-9. 1-bit data bus width***, ***Figure 24-10. 4-bit data bus width*** and ***Figure 24-11. 8-bit data bus width*** show the data packet format when data bus wide is 1-bit, 4-bit and 8-bit.

Figure 24-9. 1-bit data bus width



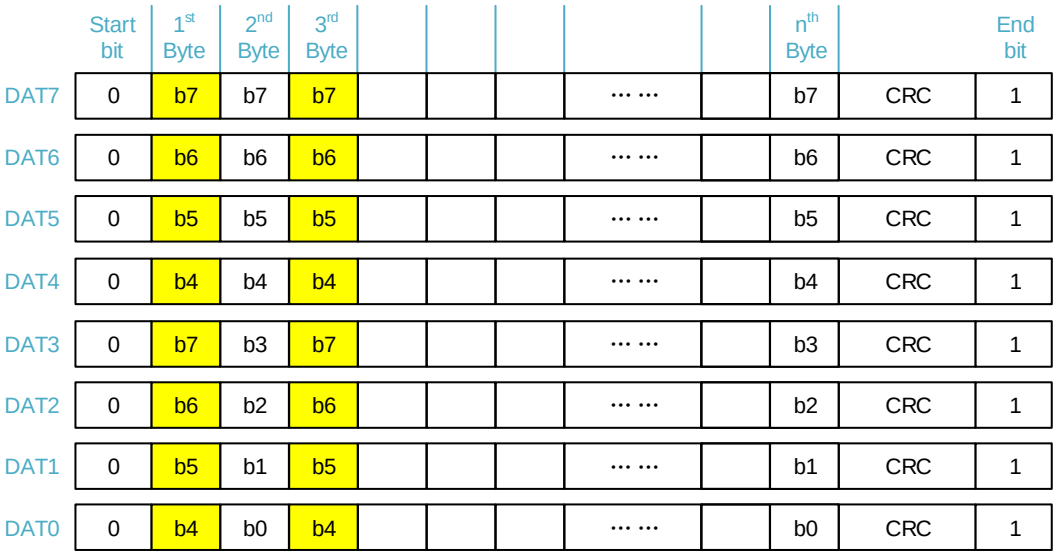
4-bit data packet format

Figure 24-10. 4-bit data bus width



8-bit data packet format

Figure 24-11. 8-bit data bus width



24.5.5. Two status fields of the card

The SD Memory supports two status fields and others just support the first one:

Card Status: Error and state information of a executed command, indicated in the response

SD Status: Extended status field of 512 bits that supports special features of the SD Memory Card and future Application-Specific features.

Card status

The response format R1 contains a 32-bit field named card status. This field is intended to transmit the card's status information (which may be stored in a local status register) to the host. If not specified , the status entries are always related to the previous issued command.

The type and clear condition fields in the table are abbreviated as follows:

Type

•E: Error bit. Send an error condition to the host. These bits are cleared as soon as the response (reporting the error) is sent out.

•S: Status bit. These bits serve as information fields only, and do not alter the execution of the command being responded to. These bits are persistent, they are set and cleared in accordance with the card status.

•R: Exceptions are detected by the card during the command interpretation and validation phase (Response Mode).

•X: Exceptions are detected by the card during command execution phase (Execution Mode).

Clear condition

•A: According to current state of the card.

•B: Always related to the previous command. Reception of a valid command will clear it (with a delay of one command).

•C: Cleared by read

Table 24-23. Card status

Bits	Identifier	Type	Value	Description	Clear Condition
31	OUT_OF_RANGE	ERX	’0’= no error ’1’= error	The command’s argument was out of the allowed range for this card.	C
30	ADDRESS_ERROR	ERX	’0’= no error ’1’= error	A misaligned address which did not match the block length was used in the command.	C
29	BLOCK_LEN_ERROR	ERX	’0’= no error ’1’= error	The transferred block length is not allowed for this card, or the number of transferred bytes does not match the block length.	C
28	ERASE_SEQ_ERROR	ER	’0’= no error ’1’= error	An error in the sequence of erase commands occurred.	C
27	ERASE_PARAM	ERX	’0’= no error ’1’= error	An invalid selection of write-blocks for erase occurred.	C
26	WP_VIOLATION	ERX	’0’= not protected ’1’= protected	Set when the host attempts to write to a protected block or to the temporary or permanent write protected card.	C
25	CARD_IS_LOCKED	SX	‘0’ = card unlocked ‘1’ = card locked	When set, signals that the card is locked by the host	A
24	LOCK_UNLOCK_FAILED	ERX	’0’= no error ’1’= error	Set when a sequence or password error has been detected in lock/unlock card command.	C
23	COM_CRC_ERROR	ER	’0’= no error ’1’= error	The CRC check of the previous command failed.	B
22	ILLEGAL_COMMAND	ER	’0’= no error ’1’= error	Command not legal for the card state.	B
21	CARD_ECC_FAILED	ERX	’0’= success	Card internal ECC was	C

Bits	Identifier	Type	Value	Description	Clear Condition
			’1’= failure	applied but failed to correct the data.	
20	CC_ERROR	ERX	’0’= no error ’1’= error	Internal card controller error.	C
19	ERROR	ERX	’0’= no error ’1’= error	A general or an unknown error occurred during the operation.	C
18	UNDERRUN	ERX	’0’= no error ’1’= error	Only for MMC. The card could not sustain data transfer in stream read mode.	C
17	OVERRUN	ERX	’0’= no error ’1’= error	Only for MMC. The card could not sustain data programming in stream write mode.	C
16	CID/ CSD_OVERWRITE	ERX	’0’= no error ’1’= error	Can be either one of the following errors: - The read only section of the CSD does not match the card content. - An attempt to reverse the copy (set as original) or permanent WP(unprotected) bits was made.	C
15	WP_ERASE_SKIP	ERX	’0’= not protected ’1’= protected	Set when only partial address space was erased due to existing write protected blocks or the temporary or permanent write protected card was erased.	C
14	CARD_ECC_DISABLED	SX	’0’= enabled ’1’= disabled	The command has been executed without using the internal ECC.	A
13	ERASE_RESET	SR	’0’= cleared ’1’= set	An erase sequence was cleared before executing because an out of erase sequence command was received.	C
[12:9]	CURRENT_STATE	SX	0 = idle 1 = ready 2 = identification 3 = stand by	The state of the card when receiving the command. If the command execution causes a state change, it will be	B

Bits	Identifier	Type	Value	Description	Clear Condition
			4 = transfer 5 = send data 6 = receive data 7 = programming 8 = disconnect 9-14 = reserved 15 = reserved for I/O mode	visible to the host in the response to the next command. The four bits are interpreted as a binary coded number between 0 and 15.	
8	READY_FOR_DATA	SX	'0'= not ready '1'= ready	Corresponds to buffer empty signaling on the bus.	A
7	SWITCH_ERROR	EX	'0'= no error '1'= switch error	If set, the card don't switch to the expected mode as requested by the SWITCH command.	B
6	Reserved				
5	APP_CMD	SR	'0'= enabled '1'= disabled	The card will expect ACMD, or an indication that the command has been interpreted as ACMD.	C
4	Reserved				
3	AKE_SEQ_ERROR	ER	'0'= no error '1'= error	Only for SD memory. Error in the sequence of the authentication process.	C
2	Reserved for application specific commands.				
[1:0]	Reserved for manufacturer test mode.				

Note: 18, 17, 7 bits are only for MMC. 14, 3 bits are only for SD memory.

SD status register

The SD Status contains status bits that are related to the SD Memory Card proprietary features and may be used for future application-specific usage. The size of the SD Status is one data block of 512 bits. The content of this register is transmitted to the Host over the DAT bus along with a 16-bit CRC. The SD Status is sent to the host over the DAT bus as a response to ACMD13 (CMD55 followed with CMD13). ACMD13 can be sent to a card only in 'transfer state' (card is selected). The SD Status structure is described below.

The same abbreviation for 'type' and 'clear condition' were used as for the Card Status above.

Table 24-24. SD status

Bits	Identifier	Type	Value	Description	Clear Condition
[511:5	DAT_BUS_WIDTH	SR	'00'= 1 (default)	Shows the currently defined	A

Bits	Identifier	Type	Value	Description	Clear Condition
10]			‘01’= reserved ‘10’= 4 bit width ‘11’= reserved	data bus width that was defined by SET_BUS_WIDTH command	
509	SECURED_MODE	SR	’0’= Not in the mode ’1’= In Secured Mode	Card is in Secured Mode of operation (refer to the “SD Security Specification”).	A
[508:496]	reserved				
[495:480]	SD_CARD_TYPE	SR	The following cards are currently defined: ’0000’= Regular SD RD/WR Card. ’0001’= SD ROM Card '0002'= OTP	In the future, the 8 LSBs will be used to define different variations of an SD Memory Card (Each bit will define different SD Types). The 8 MSBs will be used to define SD Cards that do not comply with current SD Physical Layer Specification.	A
[479:448]	SIZE_OF_PROTECTED_AREA	SR	Size of protected area	(See below)	A
[447:440]	SPEED_CLASS	SR	Speed class of the card	(See below)	A
[439:432]	PERFORMANCE_MOVE	SR	Performance of move indicated by 1 [MB/s] step.	(See below)	A
[431:428]	AU_SIZE	SR	Size of AU	(See below)	A
[427:424]	reserved				
[423:408]	ERASE_SIZE	SR	Number of AUs to be erased at a time	(See below)	A
[407:402]	ERASE_TIMEOUT	SR	Timeout value for erasing areas specified by UNIT_OF_ERASE_AU	(See below)	A
[401:400]	ERASE_OFFSET	SR	Fixed offset value added to erase time.	(See below)	A
[399:3	reserved				

Bits	Identifier	Type	Value	Description	Clear Condition
12]					
[311:0]	reserved for manufacturer				

SIZE_OF_PROTECTED_AREA

Setting this field differs between SDSC and SDHC/SDXC.

In case of SDSC Card, the capacity of protected area is calculated as follows:

Protected Area = SIZE_OF_PROTECTED_AREA_* MULT * BLOCK_LEN.

SIZE_OF_PROTECTED_AREA is specified by the unit in MULT*BLOCK_LEN.

In case of SDHC and SDXC Cards, the capacity of protected area is calculated as follows:

Protected Area = SIZE_OF_PROTECTED_AREA

SIZE_OF_PROTECTED_AREA is specified by the unit in byte.

SPEED_CLASS

This 8-bit field indicates the Speed Class.

00h: Class 0

01h: Class 2

02h: Class 4

03h: Class 6

04h: Class 10

05h–FFh: Reserved

PERFORMANCE_MOVE

This 8-bit field indicates Pm and the value can be set by 1 [MB/sec] step. If the card does not move useing RUs, Pm should be considered as infinity. Setting to FFh means infinity. The minimum value of Pm is defined in ***Table 24-25. Performance move field***.

Table 24-25. Performance move field

PERFORMANCE_MOVE	Value Definition
00h	Sequential Write
01h	1 [MB/sec]
02h	2 [MB/sec]
.....	.....
FEh	254 [MB/sec]
FFh	Infinity

AU_SIZE

This 4-bit field indicates AU Size and the value can be selected from 16 KB.

Table 24-26. AU_SIZE field

AU_SIZE	Value Definition
0h	Not Defined
1h	16 KB
2h	32 KB
3h	64 KB
4h	128 KB
5h	256 KB
6h	512 KB
7h	1 MB
8h	2 MB
9h	4 MB
Ah	8 MB
Bh	12 MB
Ch	16 MB
Dh	24 MB
Eh	32 MB
Fh	64 MB

The maximum AU size, depends on the card capacity, is defined in ***Table 24-26. AU_SIZE field***. The card can set any AU size specified in ***Table 24-27. Maximum AU size*** that is less than or equal to the maximum AU size. The card should set smaller AU size as possible.

Table 24-27. Maximum AU size

Card Capacity	up to 64MB	up to 256MB	up to 512MB	up to 32GB	up to 2TB
Maximum AU Size	512 KB	1 MB	2 MB	4 MB1	64MB

ERASE_SIZE

This 16-bit field indicates N_{ERASE}. When N_{ERASE} of AUs are erased, the timeout value is specified by ERASE_TIMEOUT (Refer to ERASE_TIMEOUT). The host should determine proper number of AUs to be erased in one operation so that the host can indicate progress of erase operation. If this field is set to 0, the erase timeout calculation is not supported.

Table 24-28. Erase size field

ERASE_SIZE	Value Definition
0000h	Erase Time-out Calculation is not supported.
0001h	1 AU
0002h	2 AU
0003h	3 AU
.....	.....
FFFFh	65535 AU

ERASE_TIMEOUT

This 6-bit field indicates the T_{ERASE} and the value indicates erase timeout from offset when multiple AUs are erased as specified by ERASE_SIZE. The range of ERASE_TIMEOUT can be defined as up to 63 seconds and the card manufacturer can choose any combination of ERASE_SIZE and ERASE_TIMEOUT depending on the implementation. Once ERASE_TIMEOUT is determined, it determines the ERASE_SIZE. The host can determine timeout for any number of AU erase by the equation below.

$$\text{Erase timeout of X AU} = \frac{T_{ERASE}}{N_{ERASE}} * X + T_{OFFSET} \quad (24\text{-}1)$$

Table 24-29. Erase timeout field

ERASE_TIMEOUT	Value Definition
00	Erase Time-out Calculation is not supported.
01	1 [sec]
02	2 [sec]
03	3 [sec]
.....	.....
63	63 [sec]

If ERASE_SIZE field is set to 0, this field shall be set to 0.

ERASE_OFFSET

This 2-bit field indicates the T_{OFFSET} and one of four values can be selected. This field is meaningless if ERASE_SIZE and ERASE_TIMEOUT fields are set to 0.

Table 24-30. Erase offset field

ERASE_OFFSET	Value Definition
0h	0 [sec]
1h	1 [sec]
2h	2 [sec]
3h	3 [sec]

24.6. Programming sequence

24.6.1. Card identification

After the host is reset, it enters the card identification mode and looks for new cards on the bus. While in card identification mode the host resets all the cards, validates operation voltage range, identifies cards and asks them to publish Relative Card Address (RCA). This operation is done to each card separately on its own CMD line. All data communication in the Card Identification Mode uses the command line (CMD) only.

During the card identification process, the card shall operate in the clock frequency of the

identification clock rate F_{OD} (400 kHz).

Card reset

The command GO_IDLE_STATE (CMD0) is the software reset command and sets MMC and SD memory card into Idle State regardless of the current card state. The reset command (CMD0) is only used for memory or the memory portion of Combo cards. In order to reset an I/O only card or the I/O portion of a combo card, use CMD52 to write 1 to the RES bit in the CCCR. Cards in Inactive State are not affected by this command.

After power-on by the host, all cards are in Idle State, including the cards that have been in Inactive State before. After power-on or CMD0, all cards' CMD lines are in input mode, waiting for start bit of the next command. The cards are initialized with a default relative card address (RCA) and with a default driver strength with 400 KHz clock frequency.

Operating voltage range validation

At the start of communication between the host and the card, the host may not know the card supported voltage and the card may not know whether it supports the current supplied voltage. To verify the voltage, the following commands are defined in the related specification.

The SEND_OP_COND (CMD1 for MMC), SD_SEND_OP_COND (ACMD41 for SD memory), IO_SEND_OP_COND (CMD5 for SD I/O) command is designed to provide hosts with a mechanism to identify and reject cards which do not match the V_{DD} range desired by the host. This is accomplished by the host sending the required V_{DD} voltage window as the operand of this command. If the card cannot perform data transfer in the specified range it must discard itself from further bus operations and go into Inactive State. Otherwise, the card shall respond sending back its V_{DD} range.

If the card can operate on the supplied voltage, the response echoes back the supply voltage and the check pattern that were set in the command argument.

If the card cannot operate on the supplied voltage, it returns no response and stays in idle state. It is mandatory to issue CMD8 prior to ACMD41 to initialize SDHC Card. Receipt of CMD8 makes the cards realize that the host supports the Physical Layer Version 2.00 and the card can enable new functions.

Card identification process

The card identification process differs in different cards. The card can be of the type MMC, CE-ATA, SD, or SD I/O. All types of SD I/O cards are supported, that is, SDIO_IO_ONLY, SDIO_MEM_ONLY, and SDIO COMBO cards. The identification process sequence includes the following steps:

- Check if the card is connected.
- Identify the card type; SD, MMC(CE-ATA), or SD I/O.

- Send CMD5 first. If a response is received, then the card is SD I/O
- If not, send ACMD41; if a response is received, then the card is SD.
- Otherwise, the card is an MMC or CE-ATA.

■ Initialization the card according to the card type.

Use a clock source with a frequency = F_{OD} (that is, 400 KHz) and use the following command sequence:

- SD card - Send CMD0, ACMD41, CMD2, CMD3.
- SDHC card - send CMD0, CMD8, ACMD41, CMD2, CMD3.
- SD I/O - Send CMD52, CMD0, CMD5, if the card doesn't have memory port, send
- CMD3; otherwise send ACMD41, CMD11 (optional), CMD2, and CMD3.
- MMC/CE-ATA - Send CMD0, CMD1, CMD2, CMD3.

■ Identify the MMC/CE-ATA device.

- CPU should query the byte 504 (S_CMD_SET) of EXT_CSD register by sending CMD8. If bit 4 is set to 1, then the device supports ATA mode.
- If ATA mode is supported, the CPU should select the ATA mode by setting the ATA bit (bit 4) in the EXT_CSD register slice 191(CMD_SET) to activate the ATA command set. The CPU selects the command set using the SWITCH (CMD6) command.
- In the presence of a CE-ATA device, the FAST_IO (CMD39) and RW_MULTIPLE_REGISTER (CMD60) commands will succeed and the returned data will be the CE-ATA reset signature.

24.6.2. No data commands

To send any non-data command, the software needs to program the SDIO_CMDCTL register and the SDIO_CMDAGMT register with appropriate parameters. Using these two registers, the host forms the command and sends it to the command bus. The host reflects the errors in the command response through the error bits of the SDIO_STAT register.

When a response is received the host sets the CMDRECV (CRC check passed) or CCRCERR (CRC check error) bit in the SDIO_STAT register. A short response is copied in SDIO_RESP0, while a long response is copied to all four response registers. The SDIO_RESP3 bit 31 represents the MSB, and the SDIO_RESP0 bit 0 represents the LSB of a long response.

24.6.3. Single block or multiple block write

During block write (CMD24 - 27) one or more blocks of data are transferred from the host to

the card. The block consists of start bits (1 or 4 bits LOW), data block, CRC and end bits(1 or 4 bits HIGH). If the CRC fails, the card indicates the failure on the SDIO_DAT line and the transferred data are discarded and not written, and all further transmitted blocks are ignored.

If the host uses partial blocks whose accumulated length is not block aligned, block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card will detect the block misalignment error before the beginning of the first misaligned block. The card shall set the ADDRESS_ERROR error bit in the status register and ignore all further data transfer at the same time. The write operation will also be aborted if the host tries to write data on a write protected area. In this case, however, the card will set the WP_VIOLATION bit (in the status register).

Programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

Some cards may require long and unpredictable time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT0 line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) at any time, and the card will respond with its status. The status bit READY_FOR_DATA indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing CMD7 (to select a different card) which will displace the card into the Disconnect State and release the DAT line without interrupting the write operation. When reselecting the card, it will reactivate busy indication by pulling DAT to low if programming is still in progress and the write buffer is unavailable.

For SD card. Setting a number of write blocks to be pre-erased (ACMD23) will make a following Multiple Block Write operation faster compared to the same operation without preceding ACMD23. The host will use this command to define how many number of write blocks are going to be send in the next write operation.

Steps involved in a single-block or multiple-block write are:

1. Write the data size in bytes in the SDIO_DATALEN register.
2. Write the block size in bytes (BLKSZ) in the SDIO_DATACTL register; the host sends data in blocks of size BLKSZ.
3. Program SDIO_CMDAGMT register with the data address to which data should be written.
4. Program the SDIO_CMDCTL register. For SD memory and MMC cards, use CMD24 for a single-block write and CMD25 for a multiple-block write. For SD I/O cards, use CMD53 for both single-block and multiple-block transfers. For CE-ATA, first use CMD60 to write the ATA task file, then use CMD61 to write the data. After writing to the CMD register, host starts executing a command, when the command is sent to the bus, the CMDRECV

flag is set.

5. Write data to SDIO_FIFO.
6. Software should look for data error interrupts. If required, software can terminate the data transfer by sending the STOP command (CMD12).
7. When a DTEND interrupt is received, the data transfer is over. For an open-ended block transfer, if the byte count is 0, the software must send the STOP command. If the byte count is not 0, then upon completion of a transfer of a given number of bytes, the host should send the STOP command.

24.6.4. Single block or multiple block read

Block read is block oriented data transfer. The basic unit of data transfer is a block whose maximum size is defined in the CSD (READ_BL_LEN), it is always 512 bytes. If READ_BL_PARTIAL(in the CSD) is set, smaller blocks whose starting and ending address are entirely contained within 512 bytes boundary may be transmitted.

CMD17 (READ_SINGLE_BLOCK) initiates a block read and after completing the transfer, the card returns to the Transfer state. CMD18 (READ_MULTIPLE_BLOCK) starts a transfer of several consecutive blocks. CRC is appended to the end of each block, ensuring data transfer integrity.

Block Length set by CMD16 can be set up to 512 bytes regardless of READ_BL_LEN.

Blocks will be continuously transferred until a STOP_TRANSMISSION command (CMD12) is issued. The stop command has an execution delay due to the serial command transmission. The data transfer stops after the end bit of the stop command.

When the last block of user area is read using CMD18, the host should ignore OUT_OF_RANGE error that may occur even the sequence is correct.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed, the card shall detect a block misalignment at the beginning of the first misaligned block, set the ADDRESS_ERROR error bit in the status register, abort transmission and wait in the Data State for a stop command.

Steps involved in a single block or multiple block read are:

1. Write the data size in bytes in the SDIO_DATALEN register.
2. Write the block size in bytes (BLKSZ) in the SDIO_DATACTL register. The host expects data from the card in blocks of size BLKSZ each.
3. Program the SDIO_CMDAGMT register with the data address of the beginning of a data read.
4. Program the SDIO_CMDCTL. For SD and MMC cards, using CMD17 for a single-block read and CMD18 for a multiple-block read. For SD I/O cards, using CMD53 for both

single-block and multiple-block transfers. For CE-ATA, first using CMD60 to write the ATA task file, then using CMD61 to read the data. After writing to the CMD register, the host starts executing the command, when the command is sent to the bus, the CMDRECV flag is set.

5. Software should look for data error interrupts. If required, software can terminate the data transfer by sending a STOP command.
6. The software should read data from the FIFO and make space in the FIFO for receiving more data.
7. When a DTEND interrupt is received, the software should read the remaining data in the FIFO.

24.6.5. Stream write and stream read (MMC only)

Stream write

Stream write (CMD20) starts the data transfer from the host to the card beginning from the starting address until the host issues a stop command. If partial blocks are allowed (if CSD parameter WRITE_BL_PARTIAL is set) the data stream can start and stop at any address within the card address space, otherwise it shall start and stop only at block boundaries. Since the amount of data to be transferred is not determined in advance, CRC cannot be used.

If the host provides an out of range address as an argument to CMD20, the card will reject the command, remain in Transfer state and respond with the ADDRESS_OUT_OF_RANGE bit set.

Note that the stream write command works only on a 1 bit bus configuration (on DAT0). If CMD20 is issued in other bus configurations, it is regarded as an illegal command.

In order to sustain data transfer in stream mode of the card, the time it takes to receive the data (defined by the bus clock rate) must be less than the time it takes to program it into the main memory field (defined by the card in the CSD register). Therefore, the maximum clock frequency for the stream write operation is given by the following formula:

$$\text{max write frequence} = \min\left(\text{TRAN\_SPEED}, \frac{8*2^{\text{WRITE\_BL\_LEN}}-100*\text{NSAC}}{\text{TAAC}*\text{R2W\_FACTOR}}\right) \quad (24\text{-}2)$$

TRAN_SPEED: Max bus clock frequency.

WRITE_BL_LEN: Max write data block length.

NSAC: Data read access-time 2 in CLK cycles.

TAAC: Data read access-time 1.

R2W_FACTOR: Write speed factor.

All the parameters are defined in CSD register. If the host attempts to use a higher frequency,

the card may not be able to process the data and will stop programming, and while ignoring all further data transfer, wait (in the Receive-data-State) for a stop command. As the host sends CMD12, the card will respond with the TXURE bit set and return to Transfer state

Stream read

There is a stream oriented data transfer controlled by READ_DAT_UNTIL_STOP (CMD11). This command instructs the card to send its data, starting at a specified address, until the host sends a STOP_TRANSMISSION command (CMD12). The stop command has an execution delay due to the serial command transmission. The data transfer stops after the end bit of the stop command.

If the host provides an out of range address as an argument to CMD11, the card will reject the command, remain in Transfer state and respond with the ADDRESS_OUT_OF_RANGE bit set.

Note that the stream read command works only on a 1 bit bus configuration (on DAT0). If CMD11 is issued in other bus configurations, it is regarded as an illegal command.

If the end of the memory range is reached while sending data, and no stop command has been sent yet by the host, the contents of the further transferred payload is undefined. As the host sends CMD12 the card will respond with the ADDRESS_OUT_OF_RANGE bit set and return to Transfer state.

In order to sustain data transfer in stream mode of the card, the time it takes to transmit the data (defined by the bus clock rate) must be less than the time it takes to read it out of the main memory field (defined by the card in the CSD register). Therefore, the maximum clock frequency for stream read operation is given by the following formula:

$$\text{max read frequence} = \min\left(\text{TRAN\_SPEED}, \frac{8*2^{\text{READ\_BL\_LEN}}-100*\text{NSAC}}{\text{TAAC}*\text{R2W\_FACTOR}}\right) \quad (24\text{-}3)$$

TRAN_SPEED: Max bus clock frequency.

READ_BL_LEN: Max read data block length.

NSAC: Data read access-time 2 in CLK cycles.

TAAC: Data read access-time 1.

R2W_FACTOR: Write speed factor.

All the parameters are defined in CSD register. If the host attempts to use a higher frequency, the card may not be able to process the data and will stop programming, and while ignoring all further data transfer, wait (in the Receive-data-State) for a stop command. As the host sends CMD12, the card will respond with the RXORE bit set and return to Transfer state

24.6.6. Erase

The erasable unit of the MMC/SD memory is the “Erase Group”; Erase group is measured in

write blocks which are the basic writable units of the card. The size of the Erase Group is a card specific parameter and defined in the CSD.

The host can erase a contiguous range of Erase Groups. Starting the erase process is a three steps sequence. First the host defines the start address of the range using the ERASE_GROUP_START (CMD35)/ERASE_WR_BLK_START (CMD32) command, next it defines the last address of the range using the ERASE_GROUP_END (CMD36)/ERASE_WR_BLK_END(CMD33) command and finally it starts the erase process by issuing the ERASE (CMD38) command. The address field in the erase commands is an Erase Group address in byte units. The card will ignore all LSB's below the Erase Group size, effectively rounding the address down to the Erase Group boundary.

If an erase command (CMD35, CMD36, and CMD38) is received out of the defined erase sequence, the card shall set the ERASE_SEQ_ERROR bit in the status register and reset the whole sequence.

If the host provides an out of range address as an argument to CMD35 or CMD36, the card will reject the command, respond with the ADDRESS_OUT_OF_RANGE bit set and reset the whole erase sequence.

If an 'non erase' command (neither of CMD35, CMD36, CMD38 or CMD13) is received, the card shall respond with the ERASE_RESET bit set, reset the erase sequence and execute the last command.

If the erase range includes write protected blocks, they shall be left intact and only the non-protected blocks shall be erased. The WP_ERASE_SKIP status bit in the status register shall be set.

As described above for block write, the card will indicate that an erase is in progress by holding DAT0 low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

24.6.7. Bus width selection

After the host has verified the functional pins on the bus it should change the bus width configuration.

For MMC, using the SWITCH command (CMD6).The bus width configuration is changed by writing to the BUS_WIDTH byte in the Modes Segment of the EXT_CSD register (using the SWITCH command to do so). After power-on or software reset, the contents of the BUS_WIDTH byte is 0x00. If the host tries to write an invalid value, the BUS_WIDTH byte is not changed and the SWITCH_ERROR bit is set. This register is write only.

For SD memory, using SET_BUS_WIDTH command (ACMD6) to change the bus width. The default bus width after power up or GO_IDLE_STATE command (CMD0) is 1 bit. SET_BUS_WIDTH (ACMD6) is only valid in a transfer state, which means that the bus width can be changed only after a card is selected by SELECT/DESELECT_CARD (CMD7).

24.6.8. Protection management

In order to allow the host to protect data against erase or write, three methods for the cards are supported in the card:

CSD register for card protection (optional)

The entire card may be write protected by setting the permanent or temporary write protect bits in the CSD. Some cards support write protection of groups of sectors by setting the WP_GRP_ENABLE bit in the CSD. It is defined in units of WP_GRP_SIZE erase groups as specified in the CSD. The SET_WRITE_PROT command sets the write protection of the addressed write protected group, and the CLR_WRITE_PROT command clears the write protection of the addressed write protected group.

The High Capacity SD Memory Card does not support Write Protection and does not respond to write protection commands (CMD28, CMD29 and CMD30).

Write protect switch on the card (SD memory and SD I/O card)

A mechanical sliding tablet on the side of the card will be used by the user to indicate that a given card is write protected or not. If the sliding tablet is positioned in such a way that the window is open it means that the card is write protected. If the window is closed the card is not write protected.

Password card Lock/Unlock Operation

The Password Card Lock/Unlock protection is described in ***Card Lock/Unlock operation***.

24.6.9. Card Lock/Unlock operation

The password protection feature enables the host to lock a card while providing a password, which later will be used for unlocking the card. The password and its size are kept in a 128-bit PWD and 8-bit PWD_LEN registers, respectively. These registers are non-volatile so that a power cycle will not erase them.

Locked cards respond to (and execute) all commands in the basic command class (class 0), ACMD41, CMD16 and lock card command class (class 7). Thus, the host is allowed to reset, initialize, select, query for status, but not to access data on the card. If the password was previously set (the value of PWD_LEN is not 0), the card will be locked automatically after power on.

Similar to the existing CSD register write commands, the lock/unlock command is available in "transfer state" only. This means that it does not include an address argument and the card shall be selected before using it.

The card lock/unlock command has the structure and bus transaction type of a regular single block write command. The transferred data block includes all the required information of the command (password setting mode, PWD itself, card lock/unlock etc.). ***Table 24-31. Lock card data structure*** describes the structure of the command data block.

Table 24-31. Lock card data structure

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0	Reserved(all set to 0)				ERASE	LOCK_UNLOCK	CLR_PWD	SET_PWD
1	PWDS_LEN							
2	Password data(PWD)							
……								
PWDS_LEN+1								

ERASE: 1 Defines Forced Erase Operation. In byte 0, bit 3 will be set to 1 (all other bits shall be 0). All other bytes of this command will be ignored by the card.

LOCK/UNLOCK: 1 = Lock the card. 0 = Unlock the card (note that it is valid to set this bit together with SET_PWD but it is not allowed to set it together with CLR_PWD).

CLR_PWD: 1 = Clear PWD.

SET_PWD: 1 = Set new password to PWD.

PWDS_LEN: Defines the following password(s) length (in bytes). In case of a password change, this field includes the total password length of old and new passwords. The password length is up to 16 bytes. In case of a password change, the total length of the old password and the new password can be up to 32 bytes.

Password data: In case of setting a new password, it contains the new password. In case of a password change, it contains the old password followed by the new password.

Setting the password

- Select a card (CMD7), if not previously selected.
- Define the block length (CMD16), given by the 8-bit card lock/unlock mode, the 8-bit password size (in bytes), and the number of bytes of the new password. In the case that a password replacement is done, then the block size shall consider that both passwords (the old and the new one) are sent with the command.
- Send the Card Lock/Unlock command with the appropriate data block size on the data line including the 16-bit CRC. The data block shall indicate the mode (SET_PWD), the length (PWDS_LEN) and the password itself. In the case that a password replacement is done, then the length value (PWDS_LEN) shall include both passwords (the old and the new one) and the password data field shall include the old password (currently used) followed by the new password. Note that the card shall handle the calculation of the new password length internally by subtracting the old password length from PWDS_LEN field.
- In the case that the sent old password is not correct (not equal in size and content), then the LOCK_UNLOCK_FAILED error bit will be set in the status register and the old password does not change. In the case that the sent old password is correct (equal in size and content), then the given new password and its size will be saved in the PWD and PWD_LEN registers, respectively.

Reset the password

- Select a card (CMD7), if not previously selected.
- Define the block length (CMD16), given by the 8-bit card lock/unlock mode, the 8-bit password size (in bytes), and the number of bytes of the currently used password.
- Send the card lock/unlock command with the appropriate data block size on the data line including the 16-bit CRC. The data block shall indicate the mode CLR_PWD, the length (PWDS_LEN), and the password itself. If the PWD and PWD_LEN content match the sent password and its size, then the content of the PWD register is cleared and PWD_LEN is set to 0. If the password is not correct, then the LOCK_UNLOCK_FAILED error bit will be set in the status register.

Locking a card

- Select a card (CMD7), if not previously selected.
- Define the block length (CMD16), given by the 8-bit card lock/unlock mode, the 8-bit password size (in bytes), and the number of bytes of the currently used password.
- Send the card lock/unlock command with the appropriate data block size on the data line including the 16-bit CRC. The data block shall indicate the mode LOCK, the length (PWDS_LEN) and the password itself.

If the PWD content is equal to the sent password, then the card will be locked and the card-locked status bit will be set in the status register. If the password is not correct, then the LOCK_UNLOCK_FAILED error bit will be set in the status register.

Unlocking the card

- Select a card (CMD7), if not previously selected.
- Define the block length (CMD16), given by the 8-bit card lock/unlock mode, the 8-bit password size (in bytes), and the number of bytes of the currently used password.
- Send the card lock/unlock command with the appropriate data block size on the data line including the 16-bit CRC. The data block shall indicate the mode UNLOCK, the length (PWDS_LEN) and the password itself.

If the PWD content is equal to the sent password, then the card will be unlocked and the card-locked status bit will be cleared in the status register. If the password is not correct, then the LOCK_UNLOCK_FAILED error bit will be set in the status register.

24.7. Specific operations

24.7.1. SD I/O specific operations

The SD I/O only card and SD I/O combo card support these specific operations:

- Read Wait operation

- Suspend/resume operation
- Interrupts

The SD I/O supports these operations only if the SDIO_DATACTL[11] bit is set, except for read suspend that does not need specific hardware implementation.

SD I/O read wait operation

The optional Read Wait (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation allows a host to signal a card that is executing a read multiple (CMD53) operation to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O card. To determine if a card supports the Read Wait protocol, the host shall test SRW capability bit in the Card Capability byte of the CCCR. The timing for Read Wait is based on the Interrupt Period. If a card does not support the Read Wait protocol, the only means a host has to stall (not abort) data in the middle of a read multiple command is to control the SDIO_CLK. The limitation of this method is that with the clock stopped, the host cannot issue any commands, and so cannot perform other operations during the delay time. Read Wait support is mandatory for the card to support suspend/resume. ***Figure 24-12. Read wait control by stopping SDIO_CLK*** and ***Figure 24-13. Read wait operation using SDIO_DAT[2]*** show the Read Wait mode about stop the SDIO_CLK and use SDIO_DAT[2].

Figure 24-12. Read wait control by stopping SDIO_CLK

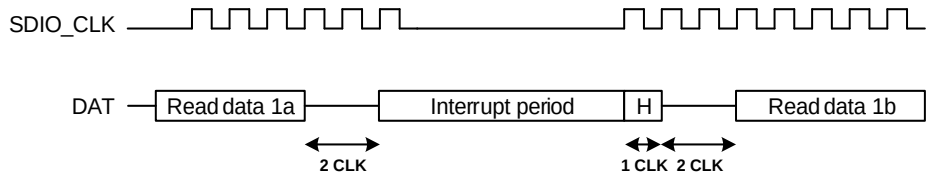


Figure 24-13. Read wait operation using SDIO_DAT[2]

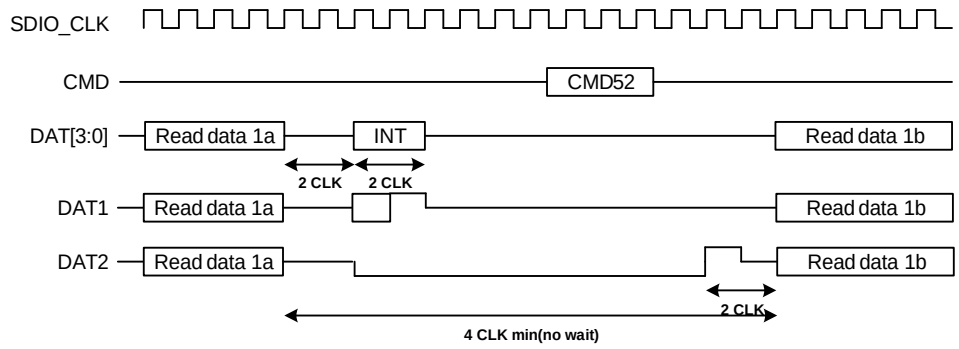


We can start the Read Wait interval before the data block is received: when the data unit is enabled (SDIO_DATACTL[0] bit set), the SD I/O specific operation is enabled (SDIO_DATACTL[11] bit set), Read Wait starts (SDIO_DATACTL[10] = 0 and SDIO_DATACTL[8] = 1) and data direction is from card to SD I/O (SDIO_DATACTL[1] = 1),

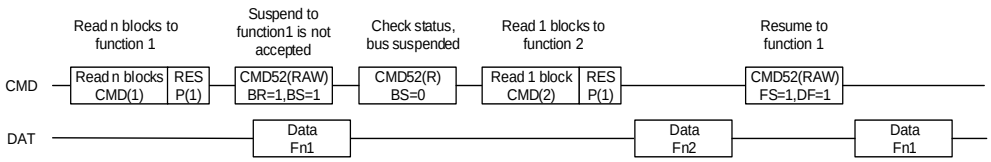
the DSM directly moves from Idle to Read Wait. In Read Wait the DSM drives SDIO_DAT[2] to 0 after 2 SDIO_CLK clock cycles. In this state, when you set the RWSTOP bit (SDIO_DATACTL[9]), the DSM remains in Wait for two more SDIO_CLK clock cycles to drive SDIO_DAT[2] to 1 for one clock cycle. The DSM then starts waiting again until it receives data from the card. The DSM will not start a Read Wait interval while receiving a block even if Read Wait start is set: the Read Wait interval will start after the CRC is received. The RWSTOP bit has to be cleared to start a new Read Wait operation. During the Read Wait interval, the SDIO can detect SD I/O interrupts on SDIO_DAT[1].

SD I/O suspend/resume operation

Within a multi-function SD I/O or a Combo card, there are multiple devices (I/O and memory) that share access to the SD bus. In order to allow the sharing of access to the host among multiple devices, SD I/O and combo cards can implement the optional concept of suspend/resume. If a card supports suspend/resume, the host may temporarily halt a data transfer operation to one function or memory (suspend) in order to free the bus for a higher priority transfer to a different function or memory. Once this higher-priority transfer is completed, the original transfer is re-started where it left off (resume).

Figure 24-14. Function2 read cycle inserted during function1 multiple read cycle shows a condition where the first suspend request is not immediately accepted. The host then checks the status of the request with a read and determines that the bus has now been released (BS=0). At this time, a read to function 2 is started. Once that single block read is completed, the resume is issued to function, causing the data transfer to resume (DF=1).

Figure 24-14. Function2 read cycle inserted during function1 multiple read cycle



When the host sends data to the card, the host can suspend the write operation. The SDIO_CMDCTL[11] bit is set and indicates to the CSM that the current command is a suspend command. The CSM analyzes the response and when the response is received from the card (suspend accepted), it acknowledges the DSM that goes Idle after receiving the CRC token of the current block.

To suspend a read operation, the DSM waits in the WaitR state, when the function to be suspended sends a complete packet just before stopping the data transaction. The application should continue reading receive FIFO until the FIFO is empty, and the DSM goes Idle state automatically.

Interrupts

In order to allow the SD I/O card to interrupt the host, an interrupt function is added to a pin on the SD interface. Pin number 8, which is used as SDIO_DAT[1] when operating in the 4-bit SD mode, is used to signal the card's interrupt to the host. The use of interrupt is optional

for each card or function within a card. The SD I/O interrupt is “level sensitive”, that is, the interrupt line shall be held active (low) until it is either recognized and acted upon by the host or de-asserted due to the end of the Interrupt Period. Once the host has serviced the interrupt, it is cleared via function unique I/O operation.

When setting the SDIO_DATACTL[11] bit SD I/O interrupts can detect on the SDIO_DAT[1] line.

Figure 24-15. Read Interrupt cycle timing shows the timing of the interrupt period for single data transaction read cycles.

Figure 24-15. Read Interrupt cycle timing

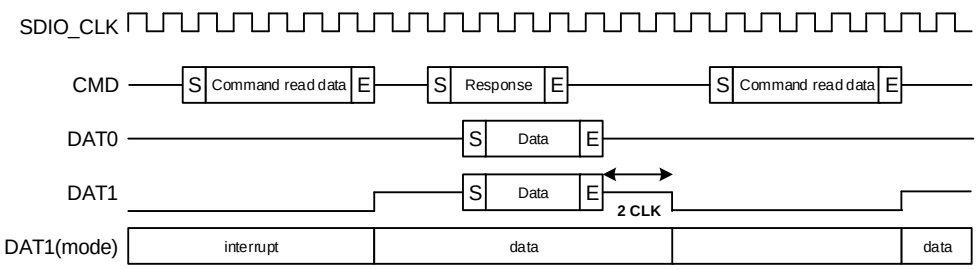


Figure 24-16. Write interrupt cycle timing

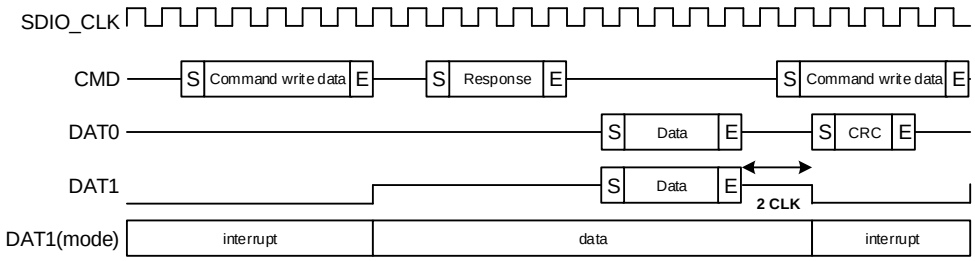

When transferring multiple blocks of data in the 4-bit SD mode, a special definition of the interrupt period is required. In order to allow the highest speed of communication, the interrupt period is limited to a 2-clock interrupt period. Card that wants to send an interrupt signal to the host shall assert DAT1 low for the first clock and high for the second clock. The card shall then release DAT1 into the hi-Z State. ***Figure 24-17. Multiple block 4-Bit read interrupt cycle timing*** shows the operation for an interrupt during a 4-bit multi-block read and ***Figure 24-18. Multiple block 4-Bit write interrupt cycle timing*** shows the operation for an interrupt during a 4-bit multi-block write

Figure 24-17. Multiple block 4-Bit read interrupt cycle timing

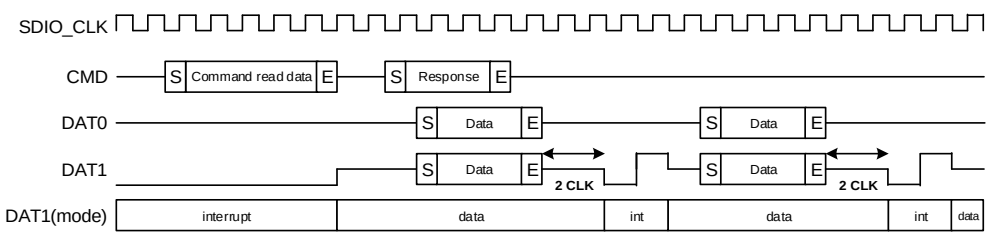

Figure 24-18. Multiple block 4-Bit write interrupt cycle timing

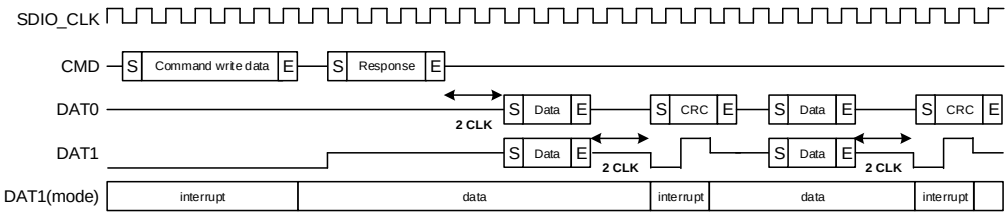


24.7.2. CE-ATA specific operations

The CE-ATA device supports these specific operations:

- Receive command completion signal
- Send command completion disable signal

The SDIO supports these operations only when SDIO_CMDCTL[14] is set.

Command completion signal

CE-ATA defines a command completion signal that the device uses to notify the host upon normal ATA command completion or when ATA command termination has occurred due to an error condition the device has encountered.

If the ‘enable CMD completion’ bit SDIO_CMDCTL[12] is set and the ‘not interrupt Enable’ bit SDIO_CMDCTL[13] is reset, the CSM waits for the command completion signal in the Waitcompl state.

When start bit is received on the CMD line, the CSM enters the Idle state. No new command can be sent for 7 bit cycles. Then, for the last 5 cycles (out of the 7) the CMD line is driven to‘1’ in push-pull mode.

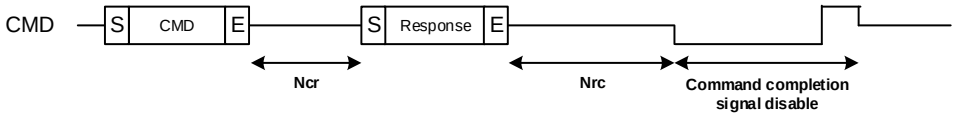
After the host detects a command completion signal from the device, it should issue a FAST_IO (CMD39) command to read the ATA Status register to determine the ending status for the ATA command.

Command completion disable signal

The host may cancel the ability for the device to return a command completion signal by issuing the command completion signal disable. The host shall only issue the command completion signal disable when it has received an R1b response for an outstanding RW_MULTIPLE_BLOCK (CMD61) command.

Command completion signal disable is sent 8 bit cycles after the reception of a short response if the ‘enable CMD completion’ bit, SDIO_CMDCTL[12] is not set and the ‘not interrupt Enable’ bit SDIO_CMDCTL[13] is reset.

Figure 24-19. The operation for command completion disable signal



24.8. Register definition

SDIO start address: 0x4001 8000

24.8.1. Power control register (SDIO_PWRCTL)

Address offset: 0x00
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														PWRCTL[1:0]	
														rw	

Bits	Fields	Descriptions
31:2	Reserved	Must be kept at reset value
1:0	PWRCTL[1:0]	SDIO power control bits. These bits control the SDIO state, card input or output. 00: SDIO power off: SDIO cmd/data state machine reset to IDLE, clock to card stopped, no cmd/data output to card 01: Reserved 10: Reserved 11: SDIO Power on

Note: Between Two write accesses to this register, it needs at least 3 SDIOCLK + 2 PCLK2 which used to sync the registers to SDIOCLK clock domain.

24.8.2. Clock control register (SDIO_CLKCTL)

Address offset: 0x04
Reset value: 0x0000 0000

This register controls the output clock SDIO_CLK.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIV[8]	Reserved														
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	HWCLKEN	CLKEDGE	BUSMODE[1:0]		CLKBYP	CLKPWRSAV	CLKEN	DIV[7:0]							

rw rw rw rw rw rw rw

Bits	Fields	Descriptions
31	DIV[8]	MSB of Clock division This field defines the MSB division between the input clock (SDIOCLK) and the output clock, refer to bit 7:0 of SDIO_CLKCTL
30:15	Reserved	Must be kept at reset value
14	HWCLKEN	Hardware Clock Control enable bit If this bit is set, hardware controls the SDIO_CLK on/off depending on the system bus is very busy or not. There is no underrun/overrun error when this bit is set, because hardware can close the SDIO_CLK when almost underrun/overrun. 0: HW Clock control is disabled 1: HW Clock control is enabled
13	CLKEDGE	SDIO_CLK clock edge selection bit 0: Select the rising edge of the SDIOCLK to generate SDIO_CLK 1: Select the falling edge of the SDIOCLK to generate SDIO_CLK
12:11	BUSMODE[1:0]	SDIO card bus mode control bit 00: 1-bit SDIO card bus mode selected 01: 4-bit SDIO card bus mode selected 10: 8-bit SDIO card bus mode selected
10	CLKBYP	Clock bypass enable bit This bit defines the SDIO_CLK is directly SDIOCLK or not. 0: NO bypass, the SDIO_CLK refers to DIV bits in SDIO_CLKCTL register. 1: Clock bypass, the SDIO_CLK is directly from SDIOCLK (SDIOCLK/1).
9	CLKPWRSAV	SDIO_CLK clock dynamic switch on/off for power saving. This bit controls SDIO_CLK clock dynamic switch on/off when the bus is idle for power saving 0: SDIO_CLK clock is always on 1: SDIO_CLK closed when bus idle
8	CLKEN	SDIO_CLK clock output enable bit 0: SDIO_CLK is disabled 1: SDIO_CLK is enabled
7:0	DIV[7:0]	Clock division This field and DIV[8] bit defines the division factor to generator SDIO_CLK clock to card. The SDIO_CLK is divider from SDIOCLK if CLKBYP bit is 0, and the SDIO_CLK frequency = SDIOCLK / (DIV[8:0] + 2).

Note: Between Two write accesses to this register, it needs at least 3 SDIOCLK + 2 PCLK2 which used to sync the registers to SDIOCLK clock domain.

24.8.3. Command argument register (SDIO_CMDAGMT)

Address offset: 0x08
Reset value: 0x0000 0000

This register defines 32 bit command argument, which will be used as part of the command (bit 39 to bit 8).
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CMDAGMT[31:16]															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CMDAGMT[15:0]															
rw															

Bits	Fields	Descriptions
31:0	CMDAGMT[31:0]	SDIO card command argument This field defines the SDIO card command argument which sent to card. This field is the bits [39:8] of command message. If the command message contains an argument, this field must update before writing SDIO_CMDCTL register when sending a command.

24.8.4. Command control register (SDIO_CMDCTL)

Address offset: 0x0C
Reset value: 0x0000 0000

The SDIO_CMDCTL register contains the command index and other command control bits to control command state machine.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	ATAEN	NINTEN	ENCMDC	SUSPEND	CSMEN	WAITDEND	INTWAIT	CMDRESP[1:0]		CMDIDX[5:0]					
	rw	rw	rw	rw	rw	rw	rw	rw		rw					

Bits	Fields	Descriptions
31:15	Reserved	Must be kept at reset value
14	ATAEN	CE-ATA command enable(CE-ATA only) If this bit is set, the host enters the CE-ATA mode, and the CSM transfers CMD61. 0: CE-ATA disable 1: CE-ATA enable

13	NINTEN	No CE-ATA Interrupt (CE-ATA only) This bit defines if there is CE-ATA interrupt or not. This bit is only used when CE-ATA card. 0: CE-ATA interrupt enable 1: CE_ATA interrupt disable
12	ENCMDC	CMD completion signal enabled (CE-ATA only) This bit defines if there is command completion signal or not in CE-ATA card. 0: no completion signal 1: have completion signal
11	SUSPEND	SD I/O suspend command(SD I/O only) This bit defines whether the CSM to send a suspend command or not. This bit is only used for SDIO card. 0: no effect 1: suspend command
10	CSMEN	Command state machine (CSM) enable bit 0: Command state machine disable (stay on CS_Idle) 1: Command state machine enable
9	WAITDEND	Waits for ends of data transfer. If this bit is set, the command state machine starts to send a command must wait the end of data transfer. 0: no effect 1: Wait the end of data transfer
8	INTWAIT	Interrupt wait instead of timeout This bit defines the command state machine to wait card interrupt at CS_Wait state in command state machine. If this bit is set, no command wait timeout generated. 0: Not wait interrupt. 1: Wait interrupt.
7:6	CMDRESP[1:0]	Command response type bits These bits define the response type after sending a command message. 00: No response 01: Short response 10: No response 11: Long response
5:0	CMDIDX[5:0]	Command index This field defines the command index to be sent to SDIO card.

Note: Between Two write accesses to this register, it needs at least 3 SDIOCLK + 2 PCLK2 which used to sync the registers to SDIOCLK clock domain.

24.8.5. Command index response register (SDIO_RSPCMDIDX)

Address offset: 0x10

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										RSPCMDIDX[5:0]					
										r					

Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5:0	RSPCMDIDX[5:0]	Last response command index Read-only bits field. This field contains the command index of the last command response received. If the response doesn't have the command index (long response and short response of R3), the content of this register is undefined.

24.8.6. Response register (SDIO_RESPx x=0..3)

Address offset: 0x14+(4*x), x=0..3

Reset value: 0x0000 0000

These register contains the content of the last card response received.

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESPx[31:16]															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESPx[15:0]															
r															

Bits	Fields	Descriptions
31:0	RESPx[31:0]	Card state. The content of the response, see ***Table 24-32. SDIO_RESPx register at different response type***.

The short response is 32 bits, the long response is 127 bits (bit 128 is the end bit 0).

Table 24-32. SDIO_RESPx register at different response type

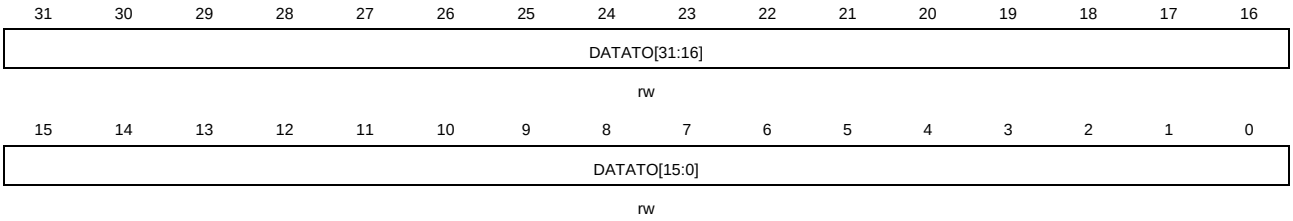
Register	Short response	Long response
SDIO_RESP0	Card response[31:0]	Card response[127:96]

Register	Short response	Long response
SDIO_RESP1	reserved	Card response [95:64]
SDIO_RESP2	reserved	Card response [63:32]
SDIO_RESP3	reserved	Card response [31:1],plus bit 0

24.8.7. Data timeout register (SDIO_DATATO)

Address offset: 0x24
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



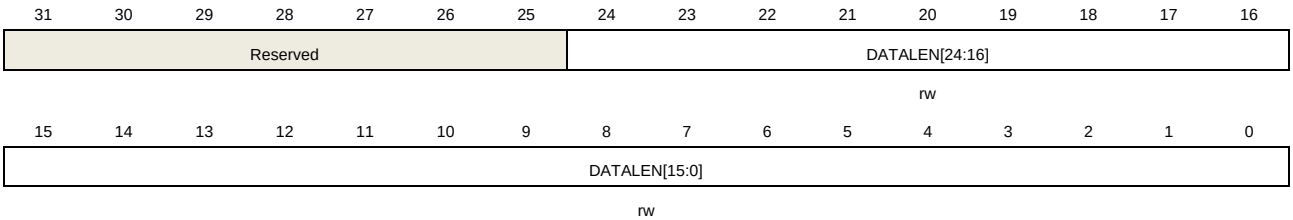
Bits	Fields	Descriptions
31:0	DATATO[31:0]	Data timeout period These bits define the data timeout period count by SDIO_CLK. When the DSM enter the state WaitR or BUSY, the internal counter which loads from this register starts decrement. The DSM timeout and enter the state Idle and set the DTTMOUT flag when the counter decreases to 0.

Note: The data timeout register and the data length register must be updated before being written to the data control register when need a data transfer.

24.8.8. Data length register (SDIO_DATALEN)

Address offset: 0x28
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:25	Reserved	Must be kept at reset value
24:0	DATALEN[24:0]	Data transfer length This register defined the number of bytes to be transferred. When the data transfer starts, the data counter loads this register and starts decrement.

Note: If block data transfer selected, the content of this register must be a multiple of the block size (refer to SDIO_DATACTL). The data timeout register and the data length register must be updated before being written to the data control register when need a data transfer.

24.8.9. Data control register (SDIO_DATACTL)

Address offset: 0x2C
Reset value: 0x0000 0000

This register controls the DSM.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				IOEN	RWTYPE	RWSTOP	RWEN	BLKSZ[3:0]				DMAEN	TRANS MOD	DATADIR	DATAEN
				rw	rw	rw	rw	rw				rw	rw	rw	rw

Note: Between Two write accesses to this register, it needs at least 3 SDIOCLK + 2 PCLK2 which used to sync the registers to SDIOCLK clock domain.

24.8.10. Data counter register (SDIO_DATACNT)

Address offset: 0x30
Reset value: 0x0000 0000

This register is read only. When the DSM from Idle to WaitR or WaitS, it loads value from data length register (SDIO_DATALEN). It decrements with the data transferred, when it reaches 0, the flag DTEND is set.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value
11	IOEN	SD I/O specific function enable(SD I/O only) 0: Not SD I/O specific function 1: SD I/O specific function
10	RWTYPE	Read wait type(SD I/O only) 0: Read Wait control using SDIO_DAT[2] 1: Read Wait control by stopping SDIO_CLK
9	RWSTOP	Read wait stop(SD I/O only) 0: No effect 1: Stop the read wait process if RWEN bit is set
8	RWEN	Read wait mode enabled(SD I/O only) 0: Read wait mode is disabled 1: Read wait mode is enabled
7:4	BLKSZ[3:0]	Data block size These bits defined the block size when data transfer is block transfer. 0000: block size = 2^0 = 1 byte 0001: block size = 2^1 = 2 bytes 0010: block size = 2^2 = 4 bytes 0011: block size = 2^3 = 8 bytes 0100: block size = 2^4 = 16 bytes 0101: block size = 2^5 = 32 bytes 0110: block size = 2^6 = 64 bytes 0111: block size = 2^7 = 128 bytes 1000: block size = 2^8 = 256 bytes 1001: block size = 2^9 = 512 bytes 1010: block size = 2^{10} = 1024 bytes 1011: block size = 2^{11} = 2048 bytes 1100: block size = 2^{12} = 4096 bytes 1101: block size = 2^{13} = 8192 bytes 1110: block size = 2^{14} = 16384 bytes 1111: reserved
3	DMAEN	DMA enable bit 0: DMA is disabled. 1: DMA is enabled.
2	TRANSMOD	Data transfer mode 0: Block transfer 1: Stream transfer or SDIO multibyte transfer
1	DATADIR	Data transfer direction 0: Write data to card.

		1: Read data from card.
0	DATAEN	Data transfer enable bit Write 1 to this bit to start data transfer regardless this bit is 0 or 1. The DSM moves to Readwait state if RWEN is set or to the WaitS, WaitR state depend on DATADIR bit. Start a new data transfer, it not need to clear this bit to 0.

Bits	Fields	Descriptions
31:25	Reserved	Must be kept at reset value
24:0	DATACNT[24:0]	Data count value Read-only bits field. When these bits are read, the number of remaining data bytes to be transferred is returned.

24.8.11. Status register (SDIO_STAT)

Address offset: 0x34

Reset value: 0x0000 0000

This register is read only. The following descripts the types of flag:

The flags of bit [23:22, 10:0] can only be cleared by writing 1 to the corresponding bit in interrupt clear register (SDIO_INTC).

The flags of bit [21:11] are changing depend on the hardware logic.

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								ATAEND	SDIOINT	RXDTVAL	TXDTVAL	RFE	TFE	RFF	TFF

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits	Fields	Descriptions
31:24	Reserved	Must be kept at reset value
23	ATAEND	CE-ATA command completion signal received (only for CMD61)
22	SDIOINT	SD I/O interrupt received
21	RXDTVAL	Data is valid in receive FIFO
20	TXDTVAL	Data is valid in transmit FIFO
19	RFE	Receive FIFO is empty
18	TFE	Transmit FIFO is empty When HW Flow control is enabled, TFE signals becomes activated when the FIFO

		contains 2 words.
17	RFF	Receive FIFO is full When HW Flow control is enabled, RFF signals becomes activated 2 words before the FIFO is full.
16	TFF	Transmit FIFO is full
15	RFH	Receive FIFO is half full: at least 8 words can be read in the FIFO
14	TFH	Transmit FIFO is half empty: at least 8 words can be written into the FIFO
13	RXRUN	Data reception in progress
12	TXRUN	Data transmission in progress
11	CMDRUN	Command transmission in progress
10	DTBLKEND	Data block sent/received (CRC check passed)
9	STBITE	Start bit error in the bus.
8	DTEND	Data end (data counter, SDIO_DATACNT, is zero)
7	CMDSEND	Command sent (no response required)
6	CMDRECV	Command response received (CRC check passed)
5	RXORE	Received FIFO overrun error occurs
4	TXURE	Transmit FIFO underrun error occurs
3	DTTMOUT	Data timeout The data timeout period depends on the SDIO_DATATO register.
2	CMDTMOUT	Command response timeout The command timeout period has a fixed value of 64 SDIO_CLK clock periods.
1	DTCRCERR	Data block sent/received (CRC check failed)
0	CCRCERR	Command response received (CRC check failed)

24.8.12. Interrupt clear register (SDIO_INTC)

Address offset: 0x38
Reset value: 0x0000 0000

This register is write only. Writing 1 to the bit can clear the corresponding bit in the SDIO_STAT register.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23	ATAENDC	ATAEND flag clear bit Write 1 to this bit to clear the flag.
22	SDIOINTC	SDIOINT flag clear bit Write 1 to this bit to clear the flag.
21:11	Reserved	Must be kept at reset value
10	DTBLKENDC	DTBLKEND flag clear bit Write 1 to this bit to clear the flag.
9	STBITEC	STBITE flag clear bit Write 1 to this bit to clear the flag.
8	DTENDC	DTEND flag clear bit Write 1 to this bit to clear the flag.
7	CMDSENDC	CMDSEND flag clear bit Write 1 to this bit to clear the flag.
6	CMDRECVC	CMDRECV flag clear bit Write 1 to this bit to clear the flag.
5	RXOREC	RXORE flag clear bit Write 1 to this bit to clear the flag.
4	TXUREC	TXURE flag clear bit Write 1 to this bit to clear the flag.
3	DTTMOUTC	DTTMOUT flag clear bit Write 1 to this bit to clear the flag.
2	CMDTMOUTC	CMDTMOUT flag clear bit Write 1 to this bit to clear the flag.
1	DTCRCERRC	DTCRCERR flag clear bit Write 1 to this bit to clear the flag.
0	CCRCERRC	CCRCERR flag clear bit Write 1 to this bit to clear the flag.

24.8.13. Interrupt enable register (SDIO_INTEN)

Address offset: 0x3C

Reset value: 0x0000 0000

This register enables the corresponding interrupt in the SDIO_STAT register.

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31:24	Reserved	Must be kept at reset value
23	ATAENDIE	CE-ATA command completion signal received interrupt enable Write 1 to this bit to enable the interrupt.
22	SDIOINTIE	SD I/O interrupt received interrupt enable Write 1 to this bit to enable the interrupt.
21	RXDTVALIE	Data valid in receive FIFO interrupt enable Write 1 to this bit to enable the interrupt.
20	TXDTVALIE	Data valid in transmit FIFO interrupt enable Write 1 to this bit to enable the interrupt.
19	RFEIE	Receive FIFO empty interrupt enable Write 1 to this bit to enable the interrupt.
18	TFEIE	Transmit FIFO empty interrupt enable Write 1 to this bit to enable the interrupt.
17	RFFIE	Receive FIFO full interrupt enable Write 1 to this bit to enable the interrupt.
16	TFFIE	Transmit FIFO full interrupt enable Write 1 to this bit to enable the interrupt.
15	RFHIE	Receive FIFO half full interrupt enable Write 1 to this bit to enable the interrupt.
14	TFHIE	Transmit FIFO half empty interrupt enable Write 1 to this bit to enable the interrupt.
13	RXRUNIE	Data reception interrupt enable

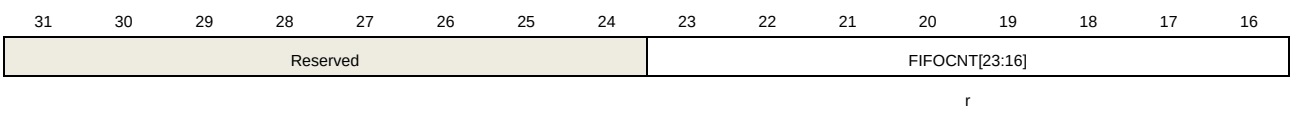
		Write 1 to this bit to enable the interrupt.
12	TXRUNIE	Data transmission interrupt enable Write 1 to this bit to enable the interrupt.
11	CMDRUNIE	Command transmission interrupt enable Write 1 to this bit to enable the interrupt.
10	DTBLKENDIE	Data block end interrupt enable Write 1 to this bit to enable the interrupt.
9	STBITEIE	Start bit error interrupt enable Write 1 to this bit to enable the interrupt.
8	DTENDIE	Data end interrupt enable Write 1 to this bit to enable the interrupt.
7	CMDSENDIE	Command sent interrupt enable Write 1 to this bit to enable the interrupt.
6	CMDRECVIE	Command response received interrupt enable Write 1 to this bit to enable the interrupt.
5	RXOREIE	Received FIFO overrun error interrupt enable Write 1 to this bit to enable the interrupt.
4	TXUREIE	Transmit FIFO underrun error interrupt enable Write 1 to this bit to enable the interrupt.
3	DTTMOUTIE	Data timeout interrupt enable Write 1 to this bit to enable the interrupt.
2	CMDTMOUTIE	Command response timeout interrupt enable Write 1 to this bit to enable the interrupt.
1	DTCRCERRIE	Data CRC fail interrupt enable Write 1 to this bit to enable the interrupt.
0	CCRCERRIE	Command response CRC fail interrupt enable Write 1 to this bit to enable the interrupt.

24.8.14. FIFO counter register (SDIO_FIFOCNT)

Address offset: 0x48

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FIFOCNT[15:0]															
r															

Bits	Fields	Descriptions
31:24	Reserved	Must be kept at reset value
23:0	FIFOCNT[23:0]	FIFO counter. These bits define the remaining number words to be written or read from the FIFO. It loads the data length register (SDIO_DATALEN[24:2] if SDIO_DATALEN is word-aligned or SDIO_DATALEN[24:2]+1 if SDIO_DATALEN is not word-aligned) when DATAEN is set, and start count decrement when a word write to or read from the FIFO.

24.8.15. FIFO data register (SDIO_FIFO)

Address offset: 0x80

Reset value: 0x0000 0000

This register occupies 32 entries of 32-bit words, the address offset is from 0x80 to 0xFC.

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FIFODT[31:16]															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FIFODT[15:0]															
rw															

Bits	Fields	Descriptions
31:0	FIFODT[31:0]	Receive FIFO data or transmit FIFO data These bits are the data of receive FIFO or transmit FIFO. Write to or read from this register is write data to FIFO or read data from FIFO.

25. External memory controller (EXMC)

25.1. Overview

The external memory controller EXMC, is used as a translator for CPU to access a variety of external memory, it automatically converts AMBA memory access protocol into a specific memory access protocol defined in the configuration register, such as SRAM, ROM, NOR Flash, PSRAM, NAND Flash, PC Card and SDRAM. Users could also tweak with the timing parameters in the configuration register to boost up memory access efficiency. EXMC access space is divided into multiple banks; each bank is assigned to access a specific memory type with flexible parameter configuration as defined in the controlling register.

25.2. Characteristics

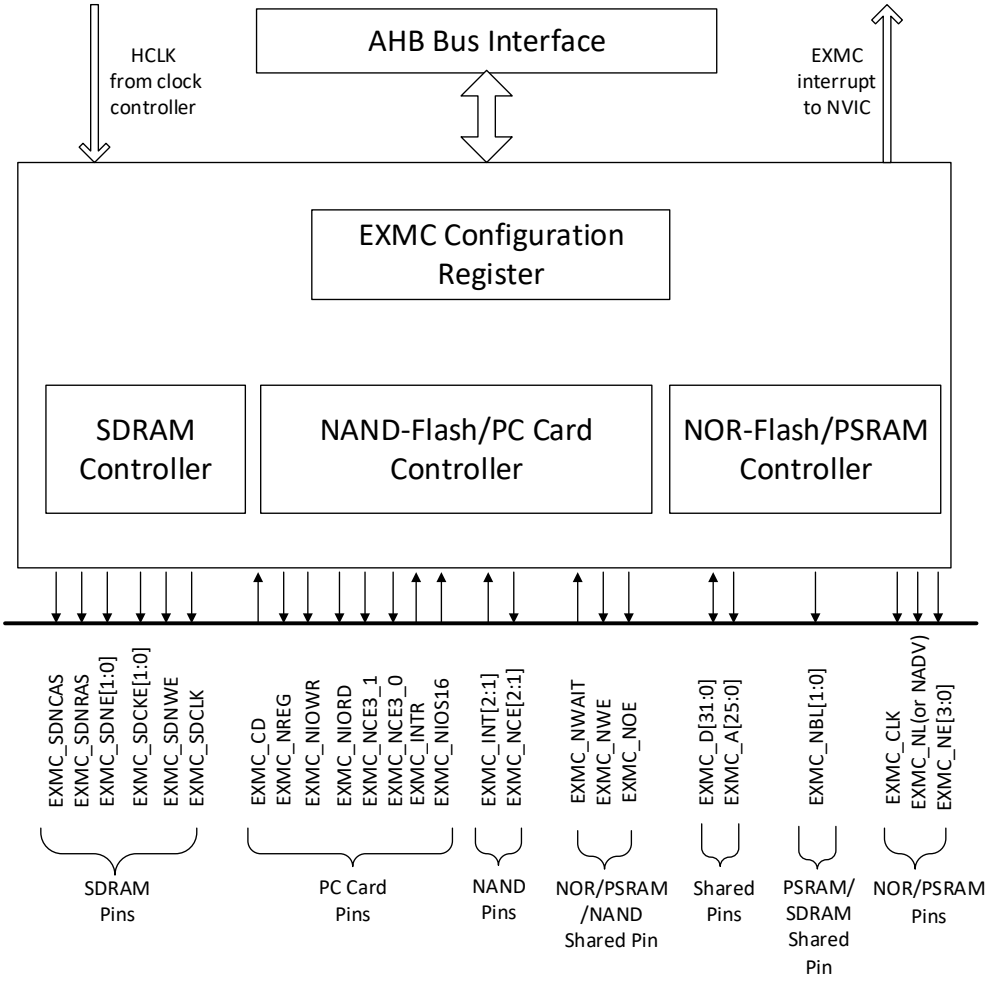
- Supported external memory:
  - SRAM
  - PSRAM/SQPI-PSRAM
  - ROM
  - NOR Flash
  - 8-bit or 16-bit NAND Flash
  - 16-bit PC Card
  - Synchronous DRAM(SDRAM)
- Protocol translation between the AMBA and the multitude of external memory protocol
- Offering a variety of programmable timing parameters to meet user's specific needs
- Each bank has its own chip-select signal which can be configured independently
- Independent read/write timing configuration to a sub-set memory type
- Embedded ECC hardware for NAND Flash access
- 8,16, or 32 bits bus width
- Address and data bus multiplexing mechanism for NOR Flash and PSRAM
- Write enable and byte select are provided as needed
- Automatic AMBA transaction split when internal and external bus width is not compatible

25.3. Function overview

25.3.1. Block diagram

EXMC is the combination of six modules: The AHB bus interface, EXMC configuration registers, NOR/PSRAM controller, NAND/PC Card controller, SDRAM controller and external device interface. AHB clock (HCLK) is the reference clock.

Figure 25-1. The EXMC block diagram



25.3.2. Basic regulation of EXMC access

EXMC is the conversion interface between AHB bus and external device protocol. 32-bit of AHB read/write accesses can be split into several consecutive 8-bit or 16-bit read/write operations respectively. In the process of data transfer, AHB access data width and memory data width may not be the same. In order to ensure consistency of data transmission, EXMC's read/write accesses follow the following basic regulation.

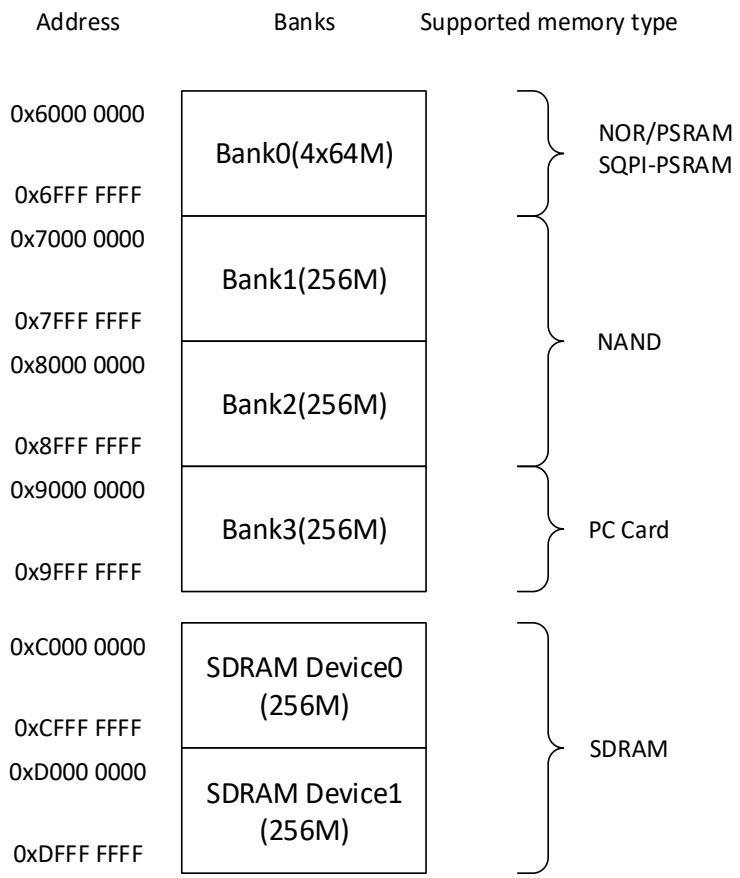
When the width of AHB bus equals to the memory bus width. No conversion is applied.

When the width of AHB bus is greater than memory bus width. The AHB accesses are automatically split into several continuous memory accesses.

When the width of AHB bus is smaller than memory bus width. If the external memory devices have the byte selection function, such as SRAM, ROM. PSRAM, SDRAM, the application can access the corresponding byte through their byte lane EXMC_NBL[1:0]. Otherwise, write operation is prohibited, but read operation is allowed unconditionally. (See ***Table 25-19. Bank1/2/3 of EXMC support the memory and access mode***)

25.3.3. External device address mapping

Figure 25-2. EXMC memory banks



EXMC access space is divided into multiple banks. Each bank is 256 Mbytes. The first bank (Bank0) is further divided into four Regions, and each Region is 64 Mbytes. Bank1 and Bank2 is each divided into two spaces, the attribute memory space and the common memory space. Bank3 is divided into three spaces, which are the attribute memory space, the common memory space and the I/O memory space.

Each bank or region has a separate chip-select control signal, which can be configured independently.

Bank0 is used for NOR and PSRAM device access.

Bank1 and Bank2 are used to access NAND Flash exclusively.

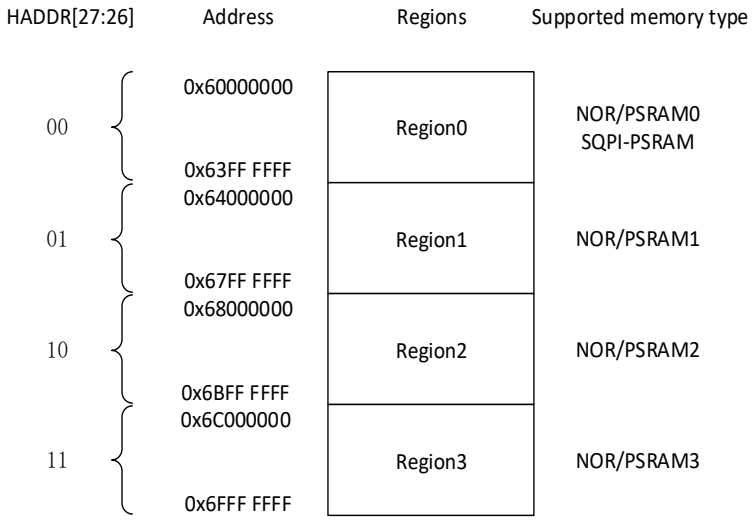
Bank3 is used for PCCard access.

SDRAM Device0 and Device1 are used for Synchronous DRAM (SDRAM) access.

NOR/PSRAM address mapping

Figure 25-3. Four regions of bank0 address mapping reflects the address mapping of the four regions of bank0. Internal AHB address lines HADDR [27:26] bit are used to select the four regions.

Figure 25-3. Four regions of bank0 address mapping



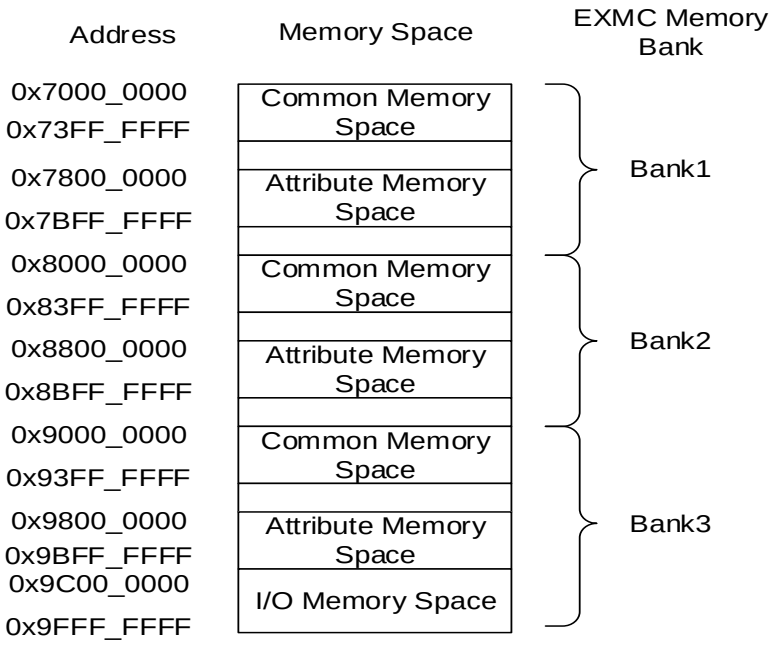
HADDR[25:0] is the byte address whereas the external memory may not be byte accessed, this will lead to address inconsistency. EXMC can adjust HADDR to accommodate the data width of the external memory according to the following rules.

- When data bus width of the external memory is 8-bits. In this case the memory address is byte aligned. HADDR [25:0] is connected to EXMC_A [25:0] and then the EXMC_A [25:0] is connected to the external memory address lines.
- When data bus width of the external memory is 16-bits. In this case the memory address is half-word aligned. HADDR byte address must be converted into half-word aligned by connecting HADDR [25:1] with EXMC_A [24:0]. The EXMC_A [24:0] is connected to the external memory address lines.
- When data bus width of the external memory is 32-bits. In this case the memory address is word aligned. HADDR byte address must be converted into word aligned by connecting HADDR [25:2] with EXMC_A [23:0]. The EXMC_A [23:0] is connected to the external memory address lines.

NAND/PC card address mapping

Bank1 and bank2 are designed to access NAND Flash, and bank3 is designed to access PC Card. Each bank is further divided into several memory spaces as shown in ***Figure 25-4. NAND/PC card address mapping***.

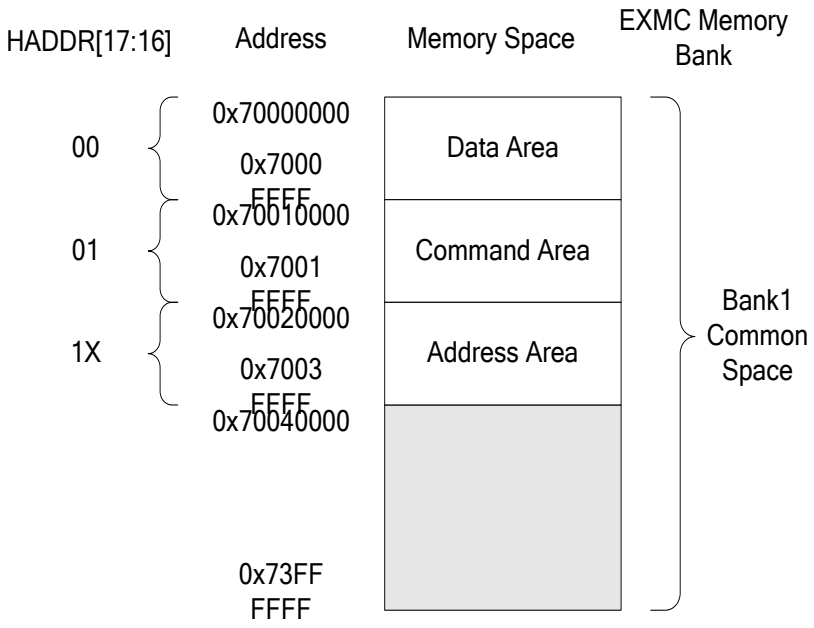
Figure 25-4. NAND/PC card address mapping



NAND address mapping

For NAND Flash, the common space and the attribute space are further-divided into three areas individually, the data area, the command area and the address area as shown in ***Figure 25-5. Diagram of bank1 common space***.

Figure 25-5. Diagram of bank1 common space



HADDR [17:16] bits are used to select one of the three areas.

- When HADDR [17:16] = 00, the data area is selected.
- When HADDR [17:16] = 01, the command area is selected.
- When HADDR [17:16] = 1X, the address area is selected.

Application software uses these three areas to access NAND Flash, their definitions are as follows.

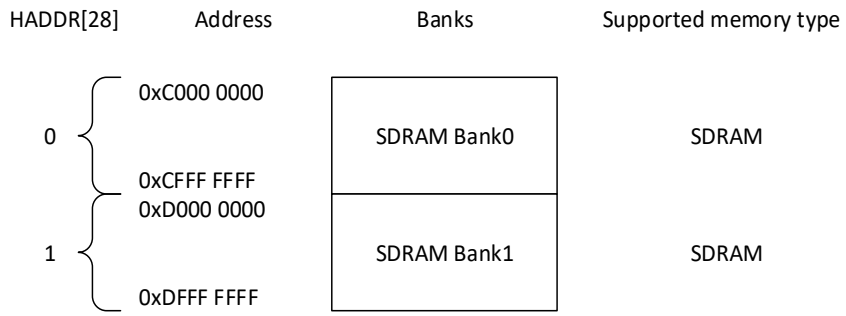
- Address area: This area is where the NAND Flash access address should be issued by software, the EXMC will pull the address latch enable (ALE) signal automatically in address transfer phase. ALE is mapped to EXMC_A [17].
- Command area: This area is where the NAND Flash access command should be issued by the software, the EXMC will pull the command latch enable (CLE) signal automatically in command transfer phase. CLE is mapped to EXMC_A [16].
- Data area: This area is where the NAND Flash read/write data should be accessed. When the EXMC is in data transfer mode, software should write the data to be transferred to the NAND Flash in this area. When the EXMC is in data reception mode, software should read the data from the NAND Flash by reading this area. Data access address is incremented automatically in consecutive mode, users do not need to be concerned with access address.

SDRAM address mapping

The HADDR [28] bit (internal AHB address line 28) is used to choose one of the two memory

banks as shown in ***Figure 25-6. SDRAM address mapping***.

Figure 25-6. SDRAM address mapping



The following table shows SDRAM address mapping of a 13-bit row and an 11-bit column configuration.

Table 25-1. SDRAM mapping

Memory width	Internal bank	Row address	Column address	Maximum memory capacity
8-bit	HADDR[25:24]	HADDR[23:11]	HADDR[10:0]	64 Mbytes: 4 x 8K x 2K
16-bit	HADDR[26:25]	HADDR[24:12]	HADDR[11:1]	128 Mbytes: 4 x 8K x 2K x 2
32-bit	HADDR[27:26]	HADDR[25:13]	HADDR[12:2]	256 Mbytes: 4 x 8K x 2K x 4

25.3.4. NOR/PSRAM controller

NOR/PSRAM memory controller controls bank0, which is designed to support NOR Flash, PSRAM, SRAM, ROM and honeycomb RAM external memory. EXMC has 4 independent chip-select signals for each of the 4 sub-banks within bank0, named NE[x] (x = 0, 1, 2, 3). Other signals for NOR/PSRAM access are shared. Each sub-bank has its own set of configuration register, but only sub-bank 0 support SQPI-PSRAM access, and owns its corresponding unique register.

Note:

In asynchronous mode, all output signals of controller will change on the rise edge of internal AHB bus clock (HCLK).

In synchronous mode, all output data of controller will change on the fall edge of extern memory device clock (EXMC_CLK).

NOR/PSRAM memory device interface description

Table 25-2. NOR flash interface signals description

EXMC Pin	Direction	Mode	Functional description
EXMC_CLK	Output	Sync	Clock signal for sync
Non-muxed EXMC_A[25:0]	Output	Async/Sync	Address bus signal
Muxed EXMC_A[25:16]			
EXMC_D[15:0]	Input/output	Async/Sync (muxed)	Address/Data bus
	Input/output	Async/Sync (non-muxed)	Data bus
EXMC_NE[x]	Output	Async/Sync	Chip selection, x=0/1/2/3
EXMC_NOE	Output	Async/Sync	Read enable
EXMC_NWE	Output	Async/Sync	Write enable
EXMC_NWAIT	Input	Async/Sync	Wait input signal
EXMC_NL(NADV)	Output	Async/Sync	Address valid

Table 25-3. PSRAM non-muxed signal description

EXMC Pin	Direction	Mode	Functional description
EXMC_CLK	Output	Sync	Clock signal for sync

	Mode B	1	NOR Flash	WDSET WASET	DSET ASET
	Mode C	1	NOR Flash with EXMC_OE toggling on data phase	WDSET WASET	DSET ASET
	Mode D	1	With address hold capability	WDSET WAHLD WASET	DSET AHLD ASET

Timing model		Extend mode	Mode description	Write timing parameter	Read timing parameter
	Mode AM	0	NOR Flash address/data mux	DSET AHLD ASET BUSLAT	DSET AHLD ASET BUSLAT
Sync	Mode E	0	NOR/PSRAM/CRAM synchronous read PSRAM/CRAM synchronous write	DLAT CKDIV	DLAT CKDIV
	Mode SM	0	NOR Flash address/data mux	DLAT CKDIV	DLAT CKDIV

As shown in ***Table 25-7. EXMC_timing_models***, EXMC NOR Flash / PSRAM controller provides a variety of timing model, users can modify those parameters listed in ***Table 25-6. NOR / PSRAM controller timing parameters*** to satisfy different external memory type and user's requirements. When extended mode is enabled via the EXMODEN bit in EXMC_SNCTLx register, different timing patterns for read and write access could be generated independently according to EXMC_SNTCFGx and EXMC_SNWTCFGx register's configuration.

Wait timing of asynchronous communication

Wait feature is controlled by the bit ASYNCWAIT in register EXMC_SNCTLx. During extern memory access, data setup phase will be automatically extended by the active EXMC_NWAIT signal if ASYNCWAIT bit is set. The extend time is calculated as follows:

1. If memory wait signal is aligned to EXMC_NOE/ EXMC_NWE:

$$T_{DATA\_SETUP} \geq \max T_{WAIT\_ASSERTION} + 4HCLK$$

2. If memory wait signal is aligned to EXMC_NE:

If $\max T_{WAIT\_ASSERTION} \geq T_{ADDRES\_PHASE} + T_{HOLD\_PHASE}$

$$T_{DATA\_SETUP} \geq \left(\max T_{WAI\_ASSERTION} - T_{ADDRE\_PHASE} - T_{HOLD\_PHASE}\right) + 4HCLK$$

Otherwise

$$T_{DATA\_SETUP} \geq 4HCLK$$

Figure 25-20. Read access timing diagram under async-wait signal assertion

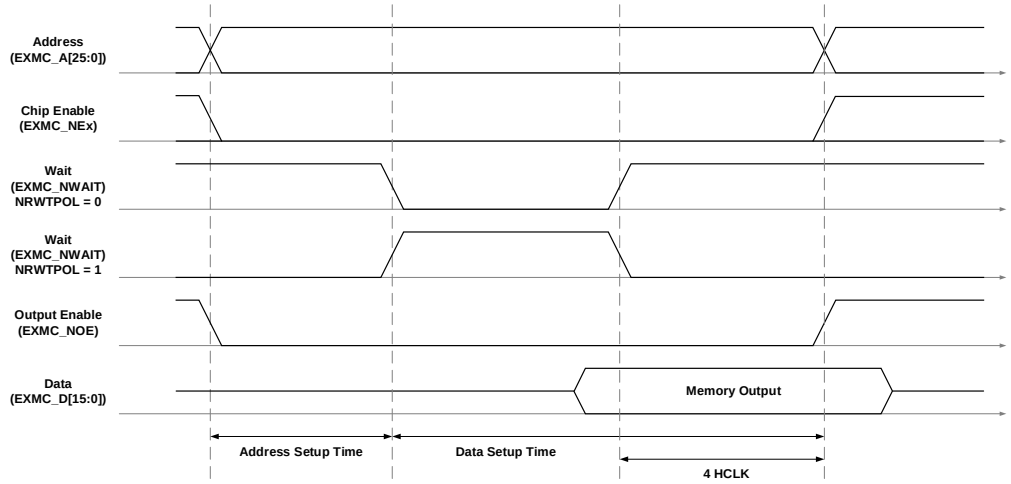

Figure 25-21. Write access timing diagram under async-wait signal assertion

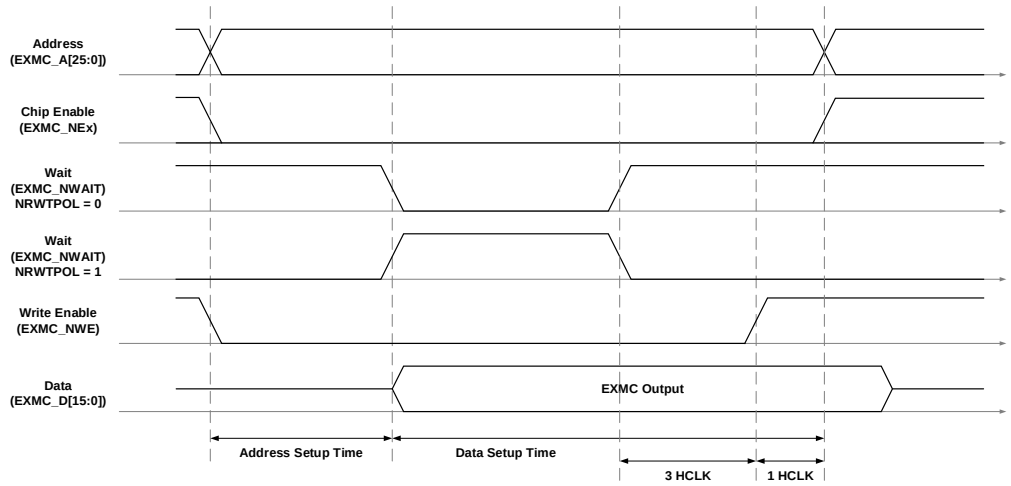

Synchronous access timing diagram

The relation between memory clock (EXMC_CLK) and system clock (HCLK) is as follows:

$$EXMC\_CLK = \frac{HCLK}{CKDIV+1}$$

CKDIV is the synchronous clock divider ratio, it is configured through the CKDIV control field in the EXMC_SNTCFGx register.

1. Data latency and NOR Flash latency

Data latency is the number of EXMC_CLK cycles to wait before sampling the data. The relationship between data latency and NOR Flash specification's latency parameter is as follows:

For NOR Flash's specification excluding the EXMC_NADV cycle, their relationship should be:

$$\text{NOR Flash latency} = \text{DLAT} + 2$$

For NOR Flash's specification including the EXMC_NADV cycle, their relationship should be:

$$\text{NOR Flash latency} = \text{DLAT} + 3$$

2. Data wait

Users should guarantee that EXMC_NWAIT signal's behavior matches that of the external device. This signal's feature is configured through the EXMC_SNCTLx registers, it is enabled by the NRWTEN bit, and the active timing could be one data cycle before the wait state or active during the active state by the configuration NRWTCFG bit, while the wait signal's polarity is set by the NRWTPOL bit.

In NOR Flash synchronous burst access mode, when NRWTEN bit in EXMC_SNCTLx register is set, EXMC_NWAIT signal will be detected after a period of data latency. If EXMC_NWAIT signal detected as valid, wait cycles will be inserted until EXMC_NWAIT becomes invalid.

- The valid polarity of EXMC_NWAIT:

NRWTPOL= 1: valid level of EXMC_NWAIT signal is high.

NRWTPOL= 0: valid level of EXMC_NWAIT signal is low.

- In synchronous burst mode, EXMC_NWAIT signal has two kinds of configurations:

NRWTCFG = 1: When EXMC_NWAIT signal is active, current cycle data is not valid.

NRWTCFG = 0: When EXMC_NWAIT signal is active, the next cycle data is not valid. It is the default state after reset.

During wait-state inserted via the EXMC_NWAIT signal, the controller continues to send clock pulses to the memory, keep the chip select and output signals availably, and ignore the invalid data signal.

3. Mode SM - Single burst transmission

For synchronous burst transmission, if the needed data of AHB is 16-bit, EXMC will perform a burst transmission whose length is 1. If the needed data of AHB is 32-bit, EXMC will make the transmission divided into two 16-bit transmissions, that is, EXMC performs a burst transmission whose length is 2.

For other configurations please refers to ***Table 25-5. EXMC bank 0 supports all transactions***.

SPI/QPI-PSRAM access timing diagram

SPI/QPI-PSRAM is controlled by EXMC memory bank0, region 0 only, it is a PSRAM with SPI and QPI interface, consisting of 6 IOs, the chip-enable, clock, and 4 data IOs, and they are summarized in the following table.

Table 25-16. SPI/QPI interface

Signal	Direction	SPI Mode	QPI Mode
EXMC_CLK	O	Serial Clock	
EXMC_NE[0]	O	Chip-Enable (active low)	
EXMC_D[0]	IO	Serial Output	Data IO[0]
EXMC_D[1]	IO	Serial Input	Data IO[1]
EXMC_D[2]	IO	X	Data IO[2]
EXMC_D[3]	IO	X	Data IO[3]

1. Controller initialization

In the beginning, users should program the SPI initialization register EXMC_SINIT. Data sampling clock edge is selected via the POL bit, read device ID length could be configured by the IDL bit, address bit number is controlled by the ADRBIT, and command bit number is set by CMDBIT.

2. Read/Write operation

Three modes of memory access are possible, SPI, QPI, and SQPI. Access mode should be configured before read/write operations. Read/write command mode is programmed by the RMODE and WMODE, wait cycle is controlled by the RWAITCYCLE and WWAITCYCLE bit, and the specific memory operating command should be programmed in RCMD and WCMD bit, these read/write settings are located in EXMC_SRCMD and EXMC_SWCMD registers respectively.

After memory access mode configuration, read/write is the same as accessing ordinary NOR Flash, data to be transferred to the external memory is written into EXMC bank0, region0, data to be received is read from the same region.

3. Read device ID

Read device ID command is a special command, it is issued by first polling the SC bit until it is 0, then set SC to 1. Lower 32-bit ID read is stored in EXMC_SIDL register, and the upper 32-bit ID read is stored in EXMC_SIDH register.

4. SPI-PSRAM access timing

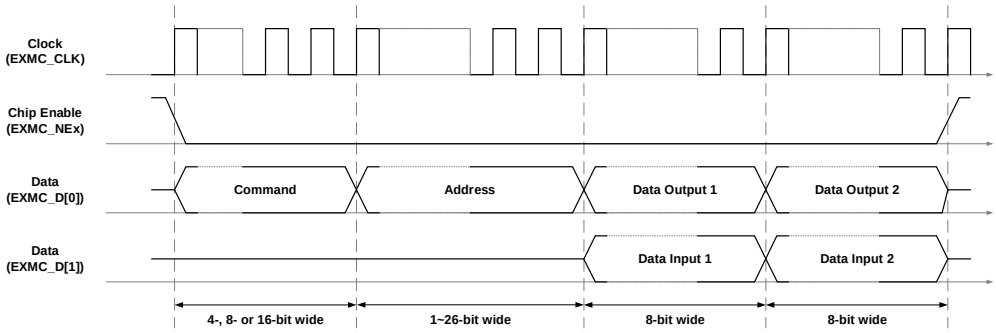
In SPI mode, the EXMC can communicate with the external memory through the SPI protocol, with 4 IOs, the clock, chip-enable, an input and an output. As shown in the diagram below, the command is first sent serially through the EXMC's data output line, which sets the external memory operating mode, followed by the address section which could be of various size, depending on EXMC's configuration, and lastly, the read or write data. Data bytes are written through the data output line, while read in through the input line.

The following SPI-PSRAM waveforms are configured with:

SADRBIT[4:0] = 24,

CMDBIT[1:0] = 1

Figure 25-24. SPI-PSRAM access



5. SQPI-PSRAM access timing

In SQPI mode, the EXMC can communicate with the external memory through the SPI protocol in command phase, and Quad SPI protocol in address and data phase with 6 IOs, the clock, chip-enable, and 4 bits data IO lines. As shown in the diagram below, the command is first sent serially through the data[0] output line, which sets the external memory operating mode, followed by the parallel address and read/write data though the 4 data IO lines.

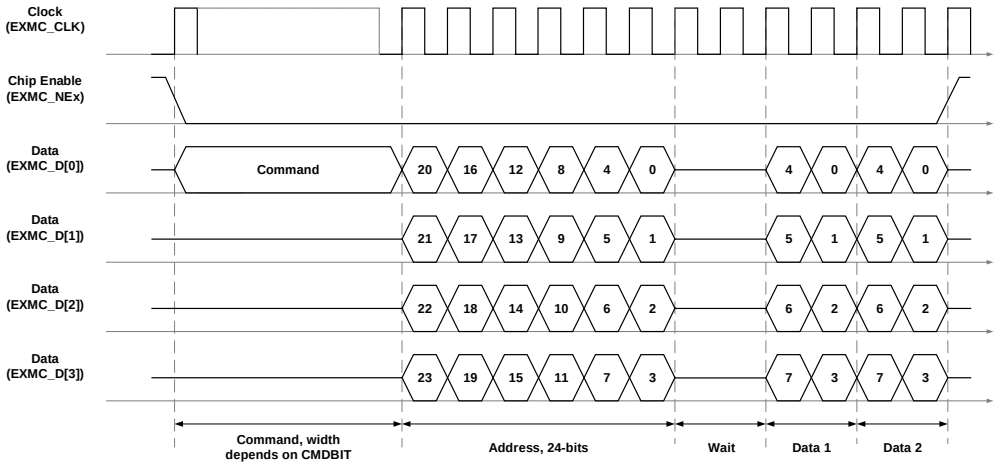
The following SQPI-PSRAM waveforms are configured with:

ADRBIT[4:0] = 24,

CMDBIT[1:0] = 1,(can be different)

RWAITCYCLE[3:0] = WWAITCYCLE[3:0] = 2 (can be different)

Figure 25-25. SQPI-PSRAM access



6. QPI-PSRAM access timing

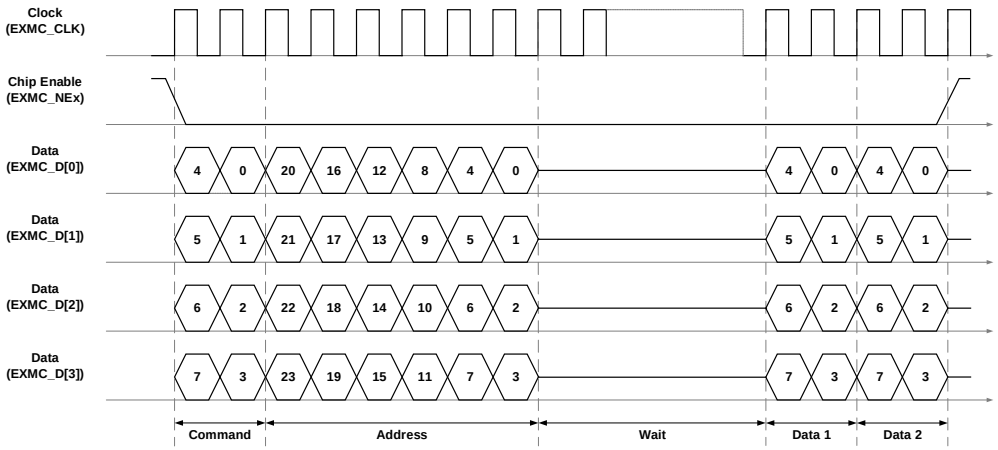
The only difference between SQPI and QPI mode is that the command is sent parallel on the 4 data IO lines as shown in the diagram below.

The following QPI-PSRAM waveforms are configured with:

ADRBIT[4:0] = 24,

CMDBIT[1:0] = 1,

Figure 25-26. QPI-PSRAM access



25.3.5. NAND flash or PC card controller

EXMC has partitioned Bank1 and Bank2 as NAND Flash access field, bank3 as PC Card access field. Each bank has its own set of control register for access timing configuration. 8- and 16-bit NAND Flash and 16-bit PC Card are supported. An ECC hardware is provided for the NAND Flash controller to ensure the robustness of data transfer and storage.

NAND flash or PC card interface function

Table 25-17. 8-bit or 16-bit NAND interface signal

EXMC Pin	Direction	Functional description
EXMC_A[17]	Output	NAND Flash address latch（ALE）
EXMC_A[16]	Output	NAND Flash command latch（CLE）
EXMC_D[7:0]/ EXMC_D[15:0]	Input /Output	8-bit multiplexed, bidirectional address/data bus
		16-bit multiplexed, bidirectional address/data bus
EXMC_NCE[x]	Output	Chip select, x = 1, 2
EXMC_NOE(NRE)	Output	Output enable
EXMC_NWE	Output	Write enable
EXMC_NWAIT/ EXMC_INT[x]	Input	NAND Flash ready/busy input signal to the EXMC, x=1, 2

Table 25-18. 16-bit PC card interface signal

EXMC Pin	Direction	Functional description
EXMC_A[10:0]	Output	Address bus of PC Card
EXMC_NIOS16	Input	Only for 16-bit I/O space data transmission width (Must be shorted to GND)
EXMC_NIORD	Output	I/O space output enable
EXMC_NIOWR	Output	I/O space write enable
EXMC_NREG	Output	Register signal indicating if access is in Common space or Attribute space
EXMC_D[15:0]	Input /Output	Bidirectional data bus
EXMC_NCE3_x	Output	Chip select(x=0,1)
EXMC_NOE	Output	Output enable
EXMC_NWE	Output	Write enable
EXMC_NWAIT	Input	PC Card wait input signal to the EXMC
EXMC_INTR	Input	PC Card interrupt input signal
EXMC_CD	Input	PC Card presence detection. Active high.

Supported memory access mode

Table 25-19. Bank1/2/3 of EXMC support the memory and access mode

Memory	Mode	R/W	AHB transaction size	Comments
8-bit NAND	Async	R	8	
	Async	W	8	
	Async	R	16	Automatically split into 2 EXMC accesses
	Async	W	16	
	Async	R	32	Automatically split into 4 EXMC accesses
	Async	W	32	
16-bit NAND/PC Card	Async	R	8	
	Async	W	8	Not support this operation

Memory	Mode	R/W	AHB transaction size	Comments
	Async	R	16	
	Async	W	16	
	Async	R	32	Automatically split into 2 EXMC accesses
	Async	W	32	

NAND flash or PC card controller timing

EXMC can generate the appropriate signal timing for NAND Flash, PC Cards and other devices. Each bank has a corresponding register to manage and control the external memory, such as EXMC_NPCTLx, EXMC_NPINTENx, EXMC_NPCTCFGx, EXMC_NPATCFGx, EXMC_PIOTCFG3 and EXMC_NECCx. Among these registers, EXMC_NPCTCFGx, EXMC_NPATCFGx, EXMC_PIOTCFG3 registers contain four timing parameters individually which are configured according to user specification and features of the external memory.

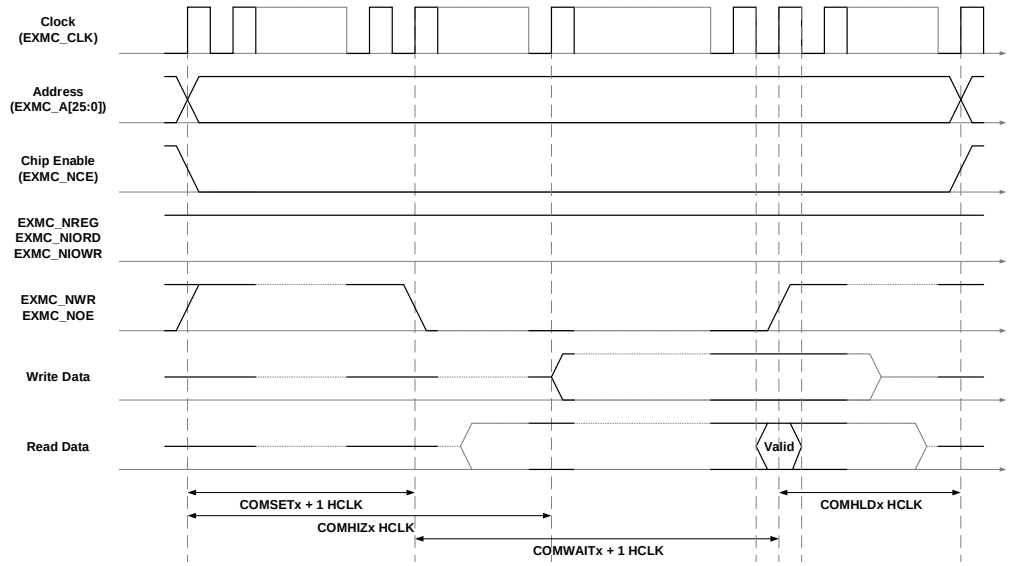
Table 25-20. NAND flash or PC card programmable parameters

Programmable parameter	W/R	Unit	Functional description	NAND Flash/ PC Card	
				Min	Max
High impedance time of the memory data bus （HIZ）	W/R	HCLK	Time to keep the data bus high impedance after starting write operation	0	255
Memory hold time（HLD）	W/R	HCLK	The number of HCLK clock cycles to keep address valid after sending the command. In write mode, it is also data hold time.	1	255
Memory wait time（WAIT）	W/R	HCLK	Minimum duration of sending command	1	256
Memory setup time（SET）	W/R	HCLK	The number of HCLK clock cycles to build address before sending command	1	256

The figure below shows the programmable parameters which are defined in the common memory space operations. The programmable parameters of Attribute memory space or I/O memory space (only for PC Card) are defined as well.

Figure 25-27. Access timing of common memory space of NAND flash or PC card

controller



NAND flash operation

When EXMC sends command or address to NAND Flash, it needs to use the command latch signal (A [16]) or address latch signal (EXMC_A [17]), namely, the CPU needs to perform write operation in particular address.

Example: NAND Flash read operation steps:

1. Configure EXMC_NPCTLx and EXMC_NPCTCFGx register. When pre-waiting is needed, EXMC_NPATCFGx has to be configured.
2. Send the command of NAND Flash read operation to the common space. Namely, during the valid period of EXMC_NCE and EXMC_NWE, when EXMC_CLE (EXMC_A [16]) becomes valid (high level), data on the I/O pins is regarded as a command by NAND Flash.
3. Send the start address of read operation to the common space. During the valid period of EXMC_NCE and EXMC_NWE, when EXMC_ALE (EXMC_A [17]) becomes valid (high level), the data on the I/O pins is regarded as an address by NAND Flash.
4. Waiting for NAND ready signal. In this period, NAND controller will maintain EXMC_NCE valid.
5. Read data byte by byte from the data area of the common space.
6. If new commands or address haven't been written, data of the next page can be read out automatically. You can also read the data of the next page by going to step 3 and then writing a new address or writing a new command and address in step 2.

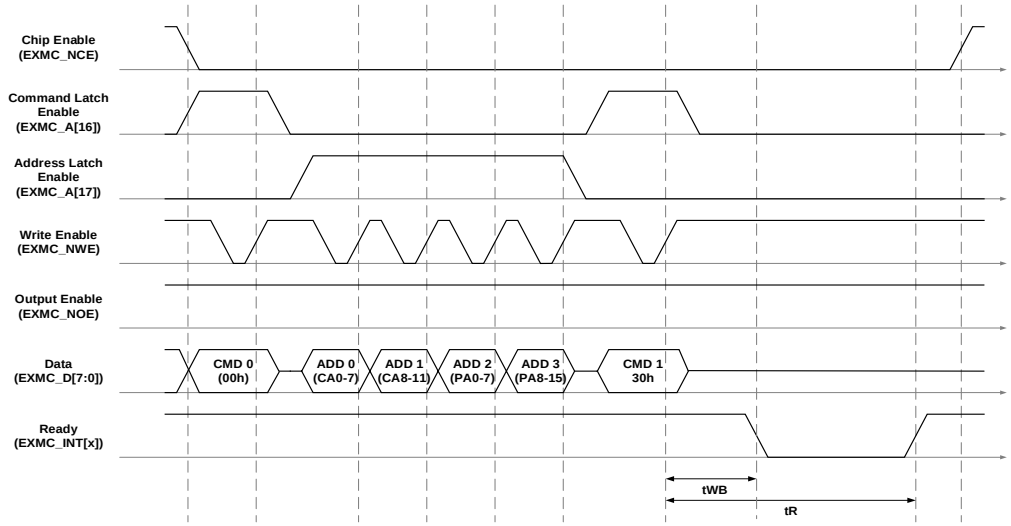
NAND flash pre-wait functionality

Some NAND Flash requires that the controller should wait for NAND Flash to be ready, after

the first command byte and following the address bytes are send, and some EXMC_NCE-sensitive NAND Flash also requires that the EXMC_NCE must remain valid before it is ready.

Taking TOSHIBA128 M x 8 bit NAND Flash as an example:

Figure 25-28. Access to none "NCE don't care" NAND Flash



1. Write CMD0 into NAND Flash bank common space command area.
2. Write ADD0 into NAND Flash bank common space address area.
3. Write ADD1 into NAND Flash bank common space address area.
4. Write ADD2 into NAND Flash bank common space address area.
5. Write ADD3 into NAND Flash bank common space address area.
6. Write CMD1 into NAND Flash bank attribute space command area.

In step 6, EXMC uses the operation timing defined in EXMC_NPATCFGx register. After a period of ATTHLD, NAND Flash waits for EXMC_INTx signal to be busy, and the time period of ATTHLD should be greater than tWB (tWB is defined as the time from EXMC_NWE high to EXMC_INTx low). For NCE-sensitive NAND Flash, after the first command byte following address bytes has been entered, EXMC_NCE must remain low until EXMC_INTx goes from low to high. The ATTHLD value of attribute space can be set in EXMC_NPATCFGx register to meet the timing requirements of tWB. MCU can use the attribute space timing when writing the first command byte following address bytes to the NAND Flash device. In other times, the MCU must use the common space timing.

NAND flash ECC calculation module

An ECC calculation hardware is implemented in bank1 and bank2 respectively. Users can choose page size according to the ECCSZ control field in the EXMC_NPCTLx register. ECC offers one bit error correction and two bits errors detection.

When NAND memory block is enabled, ECC module will detect EXMC_D[15:0], EXMC_NCE

and EXMC_NWE signals. When a data size of ECCSZ has been read or written, software must read the calculated ECC in theEXMC_NECCx register. When a recalculation of ECC is needed, software must clear the EXMC_NECCx register value by resetting ECCEN bit of EXMC_NPCTLx register to zero, and then restart ECC calculation by setting the ECCEN bit of EXMC_NPCTLx to one.

PC/CF card access

EXMC Bank3 is used exclusively for PC/CF Card, both memory and IO mode access are supported. This bank is divided further into three sub spaces, memory, attribute and IO space.

EXMC_NCE3_0 and EXMC_NCE3_1 are the byte select signals, when only EXMC_NCE3_0 is active (Low), the lower byte or upper byte is selected depending on the EXMC_A[0], while only EXMC_NCE3_1 is active (Low), the upper byte is selected which is not supported, when both of these signals are active, 16-bit operation is performed. When NDTP is reset to select PC/CF Card as external memory device, NDW must be set to 01 in EXMC_NPCTLx register to guarantee correct EXMC operation.

EXMC PC/CF card access behavior for different spaces:

- Common space: EXMC_NCE3_x (x = 0, 1) is the chip enable signal, it indicates whether 8- or 16-bit access operation is being performed. EXMC_NWE and EXMC_NOE dictates whether the on-going operation is a write or read operation, and EXMC_NREG is high during common space access.
- Attribute space: EXMC_NCE3_x (x = 0, 1) is the chip enable signal, it indicates whether 8- or 16-bit access operation is being performed. EXMC_NWE and EXMC_NOE dictates whether the on-going operation is a write or read operation, and EXMC_NREG is low during attribute space access.
- IO space: EXMC_NCE3_x (x = 0, 1) is the chip enable signal, it indicates whether 8- or 16-bit access operation is being performed. EXMC_NIOWR and EXMC_NIORD dictates whether the on-going operation is a write or read operation, and EXMC_NREG is low during IO space access.

AHB access on 16-bit PC/CF card:

1. Common space: It is usually where data are stored, it could be accessible either in byte or in half-word mode, and odd address access is not supported in byte mode. When AHB word access is selected, EXMC automatically splits it into 2 consecutive half-word access. EXMC_NREG is high when common memory is targeted. EXMC_NOE and EXMC_NWE are the read and write enable signal for this type of access.
2. Attribute space: It is usually where configuration information are stored, for byte AHB access, only even address is possible. Half-word access converts into a single byte access automatically, and word access is converted into two consecutive byte access where only the even bytes are operational. In both half-word and word access, only EXMC_NCE3_0 will be active. EXMC_NREG is low when attribute memory is targeted.

EXMC_NOE and EXMC_NWE are the read and write enable signal for this type of access.

3. IO space: Both byte and half-word AHB access are supported, in IO space memory access, EXMC_NIORD and EXMC_NIOWR act as the read and write enable signal respectively.

25.3.6. SDRAM controller

Characteristics

- Two independent SDRAM devices
- 8-,16- or 32-bit data bus width
- Up to 13-bits Row Address, 11-bits Column Address and 2-bits internal banks address
- Supported memory size: 4x16Mx32bit(256 MB), 4x16Mx16bit (128 MB) and 4x16Mx8bit (64 MB)
- AHB Word, half-word and byte access
- Independent Chip Select control for each memory device
- Independent configuration for each memory device
- Write enable and byte lane select outputs
- Automatic row and bank boundary management
- Multi-device Ping-Pong access
- SDRAM clock configured as fHCLK/2 or fHCLK /3
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Write Data FIFO with 16 x35-bit depth
- Write Address FIFO with 16x31-bit depth
- Cacheable Read Data FIFO with 6 x32-bit depth
- Cacheable Read address FIFO with 6 x14-bit depth
- Adjustable read data sample clock
- Self-refresh mode
- Power-down mode

SDRAM overview

Synchronous dynamic random-access memory (SDRAM) is a dynamic random access memory (DRAM) whose external interface is coordinated by a synchronous external clock, this clock is provided by the EXMC through the SDRAM clock (EXMC_SDCLK) pin, and its frequency could be configured to be fHCLK/2 or fHCLK /3 according to the SDRAM clock configuration bit (SDCLK) in the EXMC_SDCTLx register. Commands and data are always latched by the SDRAM on the rising edge of EXMC_SDCLK and change on its falling edge.

SDRAM is divided into several independent sections of memory called banks, allowing the device to operate on several memory access commands in an interleaved fashion to achieve greater concurrency and higher data transfer rates. Each bank could be pictured as a matrix with each entry size equals to the memory data bus width, and the size of the matrix is the number of rows by the number of columns, thus each memory bank size could be calculated as entry_size*rows*columns. When interfacing with SDRAM, users should specify the memory dimension configurations to EXMC through NBK, SDW, RAW and CAW bits in the SDRAM control register EXMC_SDCTLx.

Due to the volatile nature of SDRAM, periodic refresh cycle is necessary to maintain the stored information. Two refresh mode could be selected, self-refresh and auto-refresh mode. Self-refresh mode is typically set in low power mode when EXMC is suspended, refresh is provided by the SDRAM and timed by its internal counter. In auto-refresh mode, refresh command is provided by the EXMC, this is necessary because SDRAM must maintain the stored information during an on-going transaction, refresh commands are issued periodically on the data bus timed by ARINTV bits in EXMC_SDARI register, the number of consecutive refresh needed is configured through NARF bits in EXMC_SDCMD register. Refresh command always take precedence over other command or read/write operation to guarantee correct data storage, when memory access occurs simultaneously with refresh command, memory access is buffered and processed when refresh command is completed. If a new refresh command occurs while the previous refresh command is buffered, a refresh error flag (REIF) is raised in EXMC_SDSTAT register, and interrupt is generated if REIE is set and cleared by setting REC bit in EXMC_SDARI register.

CAS latency defines the delay in clock cycles, between the issued read command and the availability of the first piece of data form SDRAM. CAS latency is configured by the CL bits in the EXMC_SDCTLx register.

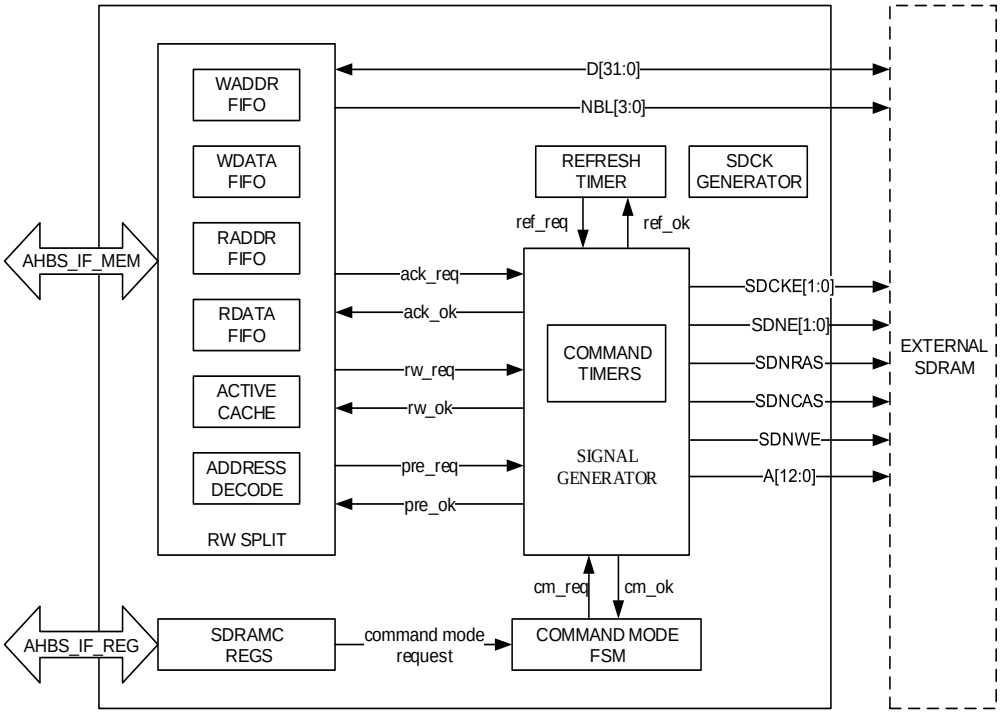
Mode Register is used to define the specific operating mode of SDRAM, such modes include burst length, burst type, CAS latency, and write mode. Users should refer to the SDRAM's specification for correct configuration. Once the operating mode has been decided, users should write the mode register content to MRC bits and issuer load mode register command through CMD bits in EXMC_SDCMD register. Load mode register command should be performed before read or write access, otherwise SDRAM might not work as expected.

SDRAM controller overview

The synchronous dynamic random-access memory controller (SDRAMC) block acts as the interface between MCU and SDRAM memory. It translates AHB transactions into the appropriate SDRAM protocol, and meanwhile, makes sure the access timing requirements of the external SDRAM devices are satisfied by the configuration of EXMC_SDTCFG register.

SDRAMC could be divided into 4 sub-modules, the read/write split, control registers, finite state machine, and signal generator. Two pairs of FIFO is implemented to increase memory access efficiency, one pair for write address and data, the other pair for read address and data. SDRAMC's block diagram is shown as follows.

Figure 25-29. SDRAM controller block diagram



The Signal Generator handles requests from Command mode FSM, Refresh Timer and the RW split module.

The command timers are composed by timing counters which take case the timing specification of the SDRAM protocol.

SDRAM commands are issued by the SDRAM controller interface in the following pattern.

Table 25-21. SDRAM command truth table

SDNE	NRAS	NCAS	SDNWE	A[n]	A[10]	A[m]	Command
H	X	X	X	X	X	X	Command inhibit (No operation)
L	H	H	H	X	X	X	No operation
L	H	H	L	X	X	X	Burst Terminate

SDNE	NRAS	NCAS	SDNWE	A[n]	A[10]	A[m]	Command
L	H	L	H	Bank	L	Col	Burst read from current row
L	H	L	H	Bank	H	Col	Burst read from current row, precharge when done
L	H	L	L	Bank	L	Col	Burst write to current row
L	H	L	L	Bank	H	Col	Burst write to current row, precharge when done
L	L	H	H	Bank	Row	Row	Active, open row for read/write
L	L	H	L	Bank	L	X	Precharge, close current row of the selected bank
L	L	H	L	X	H	X	Precharge all, close current row of all banks
L	L	L	H	X	X	X	Auto-refresh when SDCKE = 1 Self-refresh when SDCKE = 0
L	L	L	L	L	Mode	Mode	Load mode register

SDRAM controller operation sequence

IO configuration

SDRAMC IO port must be configured first to interface with external SDRAM, otherwise it is left as general purpose IOs, and could be utilized by other modules. IO ports related to SDRAM operations are summarized in the following table.

Table 25-22. IO definition of SDRAM controller

Signal	Direction	Description
EXMC_SDCLK	O	SDRAM memory clock
EXMC_SDCKE[0]	O	Clock enable for SDRAM memory 0
EXMC_SDCKE[1]	O	Clock enable for SDRAM memory 1
EXMC_SDNE[0]	O	Chip select for SDRAM memory 0, active low
EXMC_SDNE [1]	O	Chip select for SDRAM memory 1, active low
EXMC_NRAS	O	Row address strobe, active low
EXMC_NCAS	O	Column address strobe, active low
EXMC_SDNWE	O	Write enable, active low
EXMC_A[12:0]	O	Address
EXMC_A[15:14]	O	Bank address
EXMC_D[31:0]	I/O	Read/Write Data
EXMC_NBL[1:0]	O	Write data mask, the Low byte lane is accessed

Controller initialization

Users should follow procedure to initialize the SDRAM controller, the initialization sequence could be applied to a single SDRAM, or two SDRAM simultaneously. This choice is made by the device selection bits DS0 and DS1 in EXMC_SDCMD register. Initialization sequence must be performed before any read/write memory access, otherwise, EXMC's behavior is not guaranteed.

1. Control parameter specification: SDRAM control register EXMC_SDCTLx should be programed first to specify the external memory dimension, clock configuration, and read/write strategy.

2. Timing parameter specification: SDRAM timing configuration register EXMC_SDTCFGx should be programed according to external SDRAM data sheet for SDRAM controller to keep pace with the operation of the external SDRAM. RPD and ARFD must be programed in EXMC_SDTCFG0, those corresponding bit position in EXMC_SDTCFG1 are reserved.

3. Enable SDCLK: SDCLK enable command should be issued to the corresponding SDRAM devices, this is done by writing 0b001 to the CMD bits in the EXMC_SDCMD register, DS0 and DS1 selected which device will accept the command and start receiving EXMC_SDCLK.

4. Power-up delay: typical delay is around 100us.

5. Precharge all: A precharge all command should be issued to reset all the SDRAM memory banks to their idle state, waiting for subsequent operation. This is done by writing 0b010 to the CMD bits in the EXMC_SDCMD register, DS0 and DS1 defines which SDRAM device will receive this command.

6. Set auto-refresh: Auto-refresh command is sent by writing 0b011 in the CMD bits in EXMC_SDCMD register. Users should also specify the number of consecutive refresh command to issue each time by configuring the NARF bits, this configuration is requested by SDRAM specification, it is also where users should refer to.DS0 and DS1 defines which SDRAM device will receive this command.

7. Mode register configuration: Mode register is programed by writing the mode register content in MRC bits in EXMC_SDCMD register, mode register specifies the operating mode of SDRAM, such modes include burst length, burst type, CAS latency, and write mode. Users should refer to the SDRAM's specification for correct configuration. CAS latency should be the same as the CL bits in EXMC_SDCTLx register, and burst length of 1 must be selected, otherwise SDRAMC's behavior is not guaranteed. If the mode register contents are different for both SDRAM devices, this step should be repeated, targeting one device a time by the DS0 and DS1 configuration.

8. Set auto-refresh rate: Auto-refresh rate corresponds to the time between refresh cycles, users must ensure that this time period match that of the SDRAM specification.

Now SDRAMC is ready to proceed with memory access. If system reset happens, the initialization sequence must be repeated. Initialization must be performed at least once before SDRAM read/write access.

Precharge

When the memory controller needs to access a different row, it must first return that bank's sense amplifiers to an idle state, ready to sense the next row. This is known as a precharge operation, or deactivating the row. A precharge may be commanded explicitly by the

precharge all command, or it may performed automatically at the conclusion of a read or write operation. There is a minimum time, the row precharge delay (RPD), which must elapse before that banks is fully idle and it may receive another activate command.

Activate

The activate command activates an idle bank. It presents a 2-bit bank address EXMC_A[15:14] and a 13-bit row address EXMC_A[12:0], and causes a read of that row into the bank's array of 16,384 column sense amplifiers. This also known as opening the row. This operation has the side effect of refreshing the dynamic memory storage cells of that row.

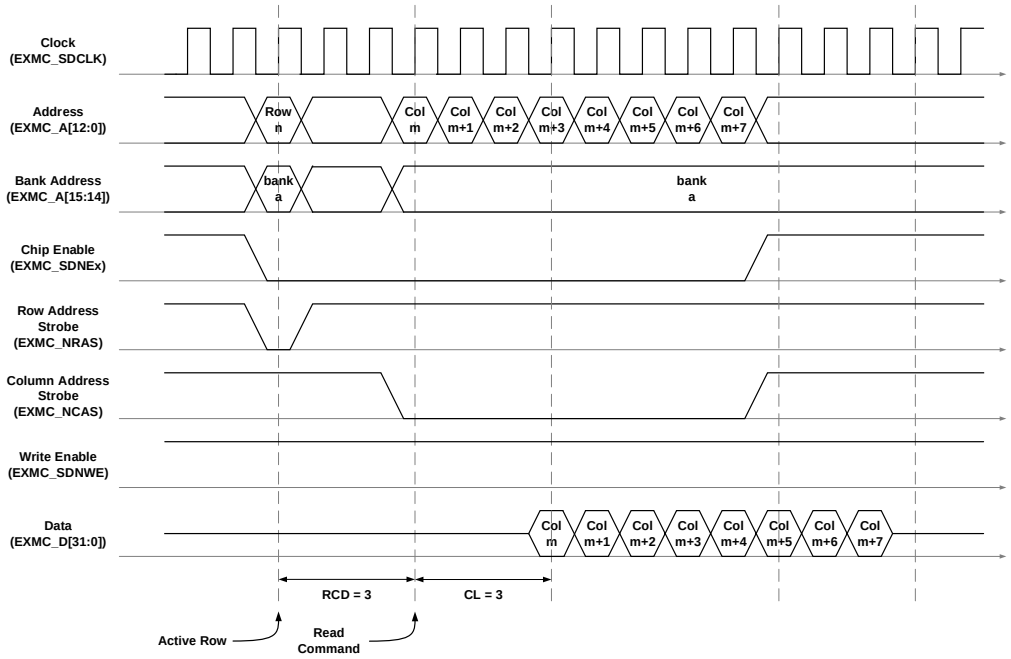
Once the row has been activated, read/write commands are possible to that row. Activation requires a minimum amount of time, called the row-to-column delay (RCD) before read/write to it may occur. This time, rounded up to the next multiple of the clock period, specifies the minimum number of wait cycles between an active command and a read/write command. During these wait cycles, additional commands may be sent to other banks, because each bank operates completely independently.

Read/Write access

SDRAMC can translate AHB single and burst read operation into single memory access. SDRAMC always keeps track of the activated row number in order to perform consecutive read access. If the next read location is in the same row or another active row, read access is proceeded without interruption, else a precharge command is issued to deactivate the current row, followed by the activation of the row where the next read access is targeted, and then the read access is performed. A read FIFO is design to cache the read data during CAS latency and pipe line delay (PIPED), Burst read (BRSTRD) must be set in order to enable the FIFO.

The following diagram shows a burst read access to an in active row, a row activation command is issued before read access. If read operation were performed on an active row, row address strobe is not necessary, only column address strobe is needed.

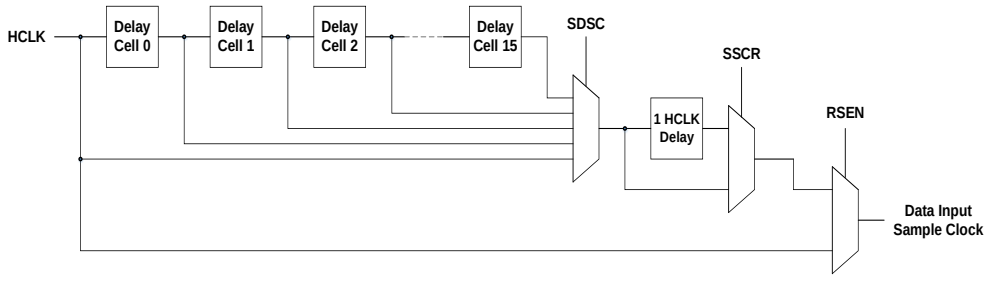
Figure 25-30. Burst read operation



An internal generated clock, which has an adjustable delay from the HCLK can be used to sample read data from external memories. This clock can be helpful when the read data can't be sampled correctly by HCLK. When this clock is enabled, the read data will be firstly stored in an asynchronous FIFO before returned to the AHB bus. Additional delays of about 2~3 HCLK may be brought into the reading command process.

A clock delay chain module is added after the HCLK input to the signal generator, this delayed clock is used as the sampling clock of the input data. The delay chain is controlled by the EXMC_SDRSCTL register, RSEN bit select whether the HCLK output is delay at all, SSCR bit select whether 1 additional HCLK cycle is added to the total delay, and SDSC select how many delay cells is add, the number of delay cell could be added is within 0 and 15. The following diagram shows how delay chain is added.

Figure 25-31. Data sampling clock delay chain

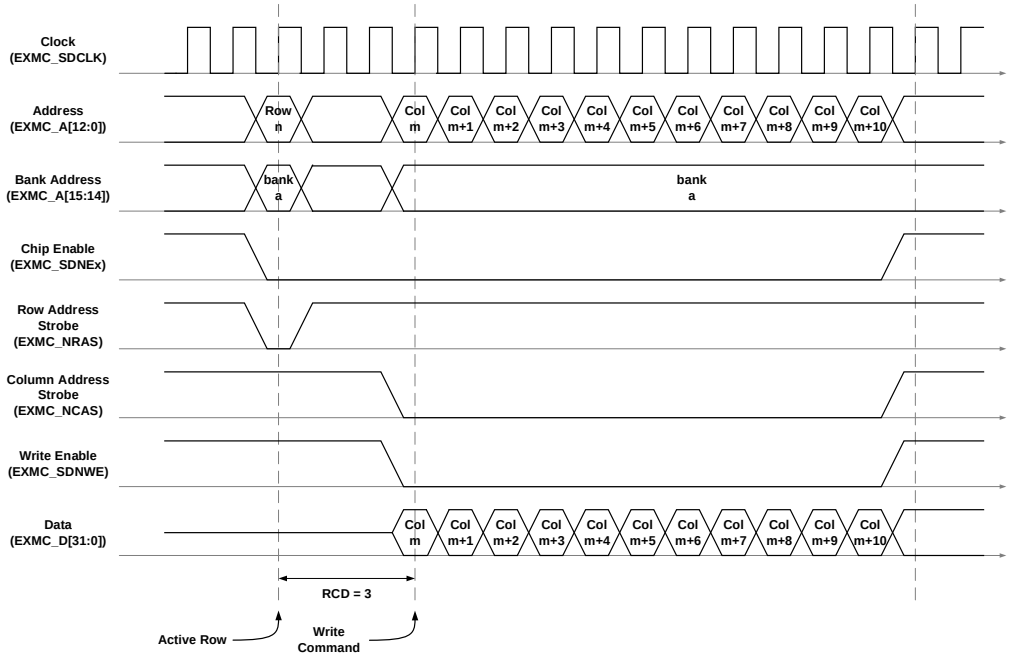


SDRAMC can translate AHB single and burst write operation into single memory access. Write protection must be disabled by resetting WPEN bit in EXMC_SDCTLx register. SDRAMC always keeps track of the activated row number in order to perform consecutive write access. If next write location is in the same row or another active row, write access is proceeded without interruption, else a precharge command is issued to deactivate the current row, followed by the activation of the row where the next write access is targeted, and then

the write access is performed.

The following diagram shows a write burst access to an inactive row, a row activation command is issued before write access. If write operations were performed on an active row, row address strobe is not necessary, only column address strobe is needed.

Figure 25-32. Burst write operation



The RW split module accepts AHB commands, and transfers them to single read/write accesses on the SDRAM memory according to the ratio of the data width between the AHB bus and the SDRAM memory interface.

Inside the RW split module, there are two write FIFOs, which buffers the data and address of the AHB write commands. When neither of the write FIFOs is empty, write access occurs.

When the BRSTRD bit of EXMC_SDCTL0 register is set, the RW split module can anticipate the next read access. The read FIFOs are used to store data read in advance during the CAS latency period (configured by the CL bits of EXMC_SDCTLx) and during the PIPED delay (configured by the PIPED bits of EXMC_SDCTL0).

The RDATA FIFO can buffers up to 6 32-bit read data words, while the RADDR FIFO carries 6 14-bit read address tags to identify each of them. Every address tag is comprised of 11 bits for the column address, 2 bits for the internal bank address and 1 bit to select the SDRAM memories.

When there is an read commands on the AHB bus, the RW split module will firstly checks whether the address matches one of the address tags, and data are directly read from the FIFO when it is true. Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

Figure 25-33. Read access when FIFO not hit (BRSTRD=1, CL=2, SDCLK=2, PIPED=2) and *Figure 25-34. Read access when FIFO hit (BRSTRD=1)* specify the Read FIFO

operation.

Figure 25-33. Read access when FIFO not hit (BRSTRD=1, CL=2, SDCLK=2, PIPED=2)

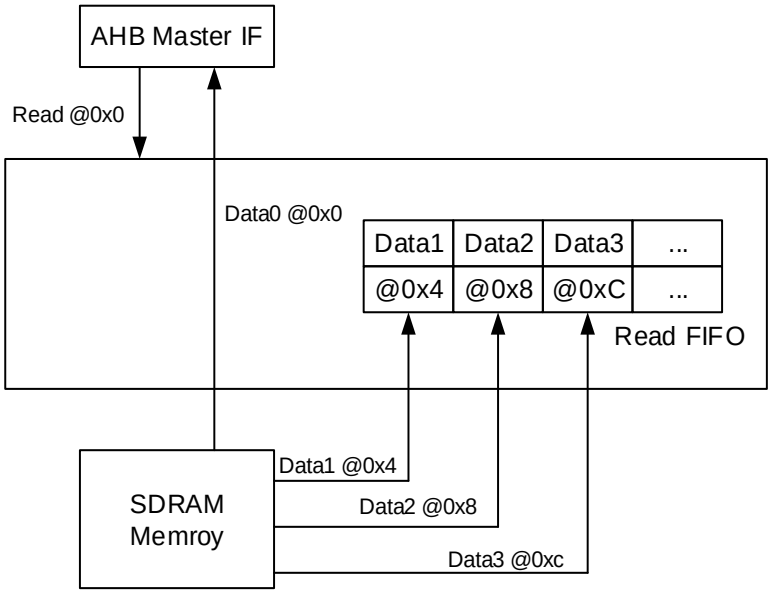


Figure 25-34. Read access when FIFO hit (BRSTRD=1)

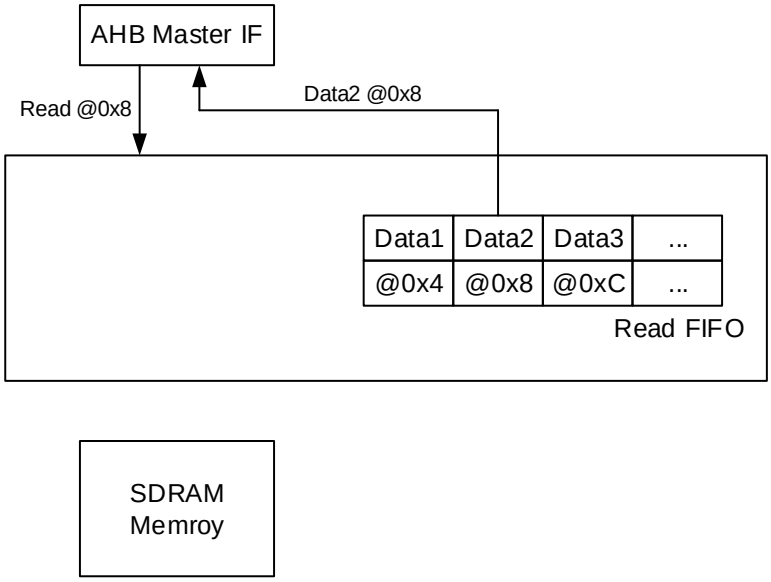

The read FIFO will be flushed and ready to be filled with new data, when a write access or a precharge command occurs.

The address decoder sub-module translate the address of the AHB bus address to chip select, internal bank address, row address and column address according to the configuration of external memory device.

The active cache sub-module records whether the internal banks (up to 8) are in the active state. When an internal bank is in active state, the corresponding row address is also recorded. When an AHB access or an auto-refresh command is issued, the RW split module will look up this record and decide whether to generate the Active/Precharge commands or not.

Before read/write operation, the targeted row must be activated, the value of EXMC_A[15:14] selects the bank, and EXMC_A[12:0] select the row. The selected row remains active until a precharge command is issued. The precharge command is used to deactivate an active row in a particular bank or the active row in all banks. A precharge command must be issued before activating a different row in the same bank. Active and precharge are automatically issued by the EXMC, its correctness depends on memory dimension configurations discussed previously, read and write timing diagram concerning automatic row activation and precharge are depicted as follows.

Figure 25-35. Cross boundary read operation

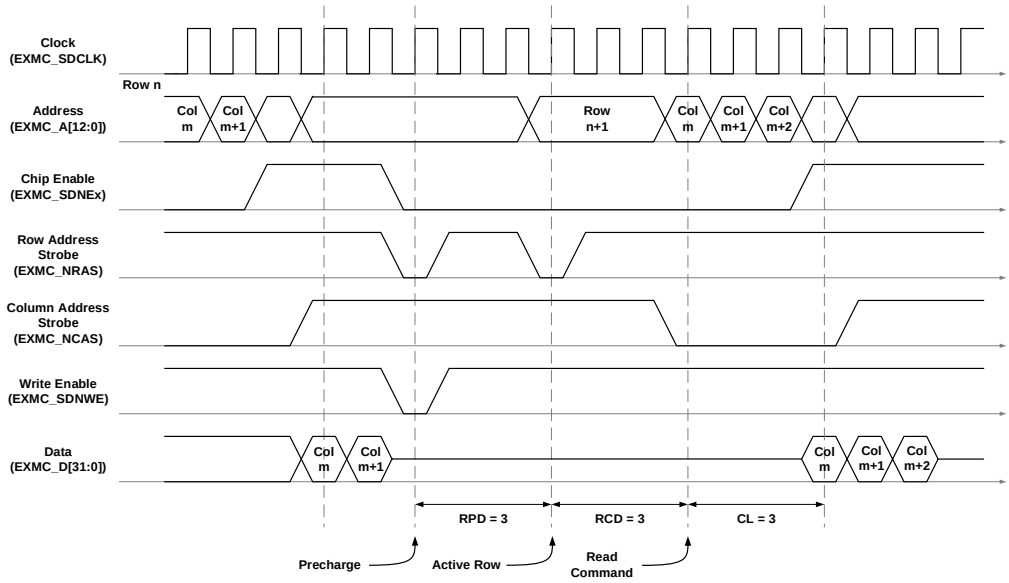

Figure 25-36. Cross boundary write operation

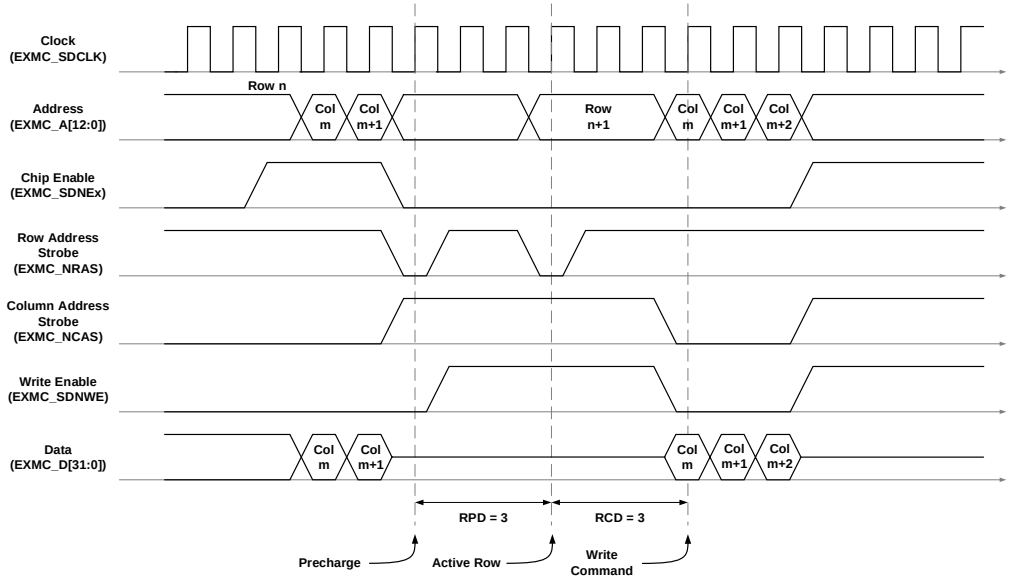


The above diagrams depict read and write timing waveform when memory access crosses row boundary, the following steps are preformed automatically:

1. Precharge the current active row.

2. Next row's activation.

3. Read/write access.

Precharge delay (PRD) and row to column delay (RCD) are added according to their configuration in EXMC_SDTCFGx register, other timing parameters should be configured as SDRAM specification requires.

When this boundary happens to be at the end of a bank, two cases are possible:

1. When the current bank is not the last bank, the activation of the first row of the next bank is performed, and this supports all row, column, and bus width configuration.

2. When the current bank is the last bank, and row, column, and bus width are configured as, 13-bit, 11-bit, and 32-bit respectively, EXMC continues to read/write from the second SDRAM device (SDRAM device 1), assuming that the current SDRAM is device 0.

Low power modes

Two low power mode are supported:

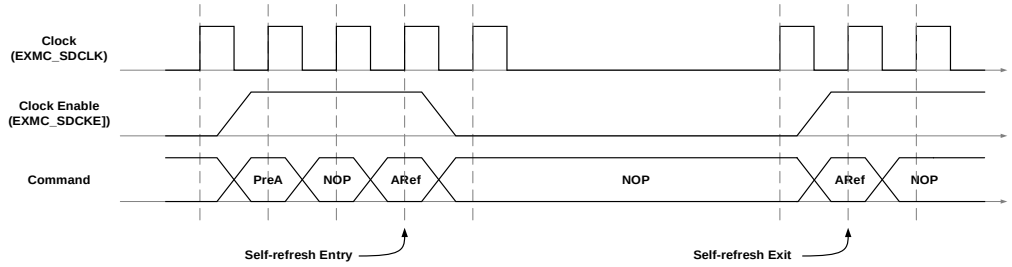
1. Self-refresh mode: In self-refresh mode, refresh is provided by the SDRAM itself to maintain data integrity without external clock (EXMC_SDCLK). It is entered by writing 0b101 to CMD bits in EXMC_SDCMD register, DS0 andDS1 determines which SDRAM device will receive the command. EXMC_SDCLK stops running after a RASD delay if this command is issued to both SDRAM devices or one of the SDRAM device is not initialized.

2. Power-down mode: In power-down mode, refresh is provided by the SDRAM controller. It is entered by writing 0b110 to CMD bits in EXMC_SDCMD register, DS0 and DS1 determines which SDRAM device will receive the command. If the write data FIFO is not empty, all data are sent to the memory before activating power-down mode.

The Command Mode FSM also controls the switching process of between the normal mode and the low-power modes (self-refresh/power-down).

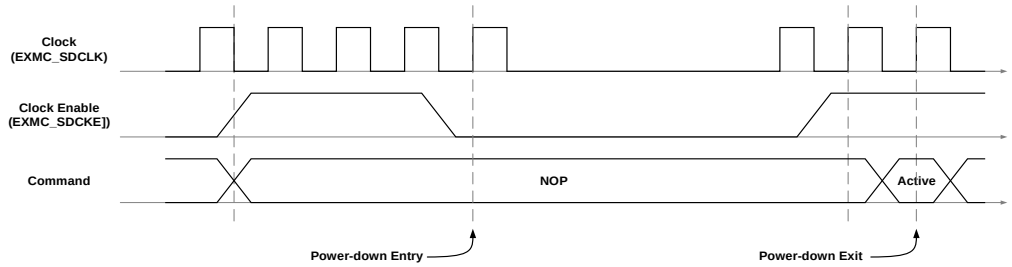
The SDRAM controller returns to normal mode from self-refresh mode when a read/write access occurs. If a read/write access occurs while the SDRAM controller is entering self-refresh mode, the self-refresh entry process will be interrupted, and the SDRAM controller remains in normal mode after the read/write access completed.

Figure 25-37. Process for self-refresh entry and exit



If an auto-refresh request occurs when the SDRAM controller is in power-down mode, the SDRAM controller returns to normal mode, issues the Precharge all and Auto-Refresh command sequence, and enters power-down mode again automatically.

Figure 25-38. Process for power-down entry and exit



Status and interrupt

The not ready status NRDY bit in EXMC_SDSTAT register specifies whether the SDRAM controller is ready for a new command, this bit is cleared immediately after the command in the SDRAMC's internal register is sent.

Device0 and Device1 status bits STA0 and STA1 in EXMC_SDSTAT register defines the status of SDRAM deivce0 and device1 respectively, 0b00 represents normal mode, 0b01 indicates that the corresponding SDRAM devices is in self-refresh mode, and 0b10 signifies the power-down mode.

If a new refresh request occurs while the previous refresh command has not been served yet, a refresh error flag (REIF) is raised in EXMC_SDSTAT register, and interrupt is generated if REIE is set, refresh error flag is cleared by setting REC bit in EXMC_SDARI register.

25.4. Register definition

EXMC start address: 0x6000 0000

25.4.1. NOR/PSRAM controller registers

The peripheral registers have to be accessed by words (32-bit).

SRAM/NOR flash control registers (EXMC_SNCTLx) (x=0, 1, 2, 3)

Address offset: 0x00 + 8 * x, (x = 0, 1, 2, and 3)

Reset value: 0x0000 30DB for region0, and 0x0000 30D2 for region1, region2, and region3

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved												SYNCWR	Reserved		
												rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ASYNCWAIT	EXMODEN	NRWTEN	WREN	NRWTCFG	WRAPEN	NRWTPOL	SBRSTEN	Reserved	NREN	NRW[1:0]		NRTP[1:0]		NRMUX	NRBKEN
rw	rw	rw	rw	rw	rw	rw	rw		rw	rw		rw		rw	rw

Bits	Fields	Descriptions
31:20	Reserved	Must be kept at reset value.
19	SYNCWR	Synchronous write 0: Asynchronous write 1: Synchronous write
18:16	Reserved	Must be kept at reset value.
15	ASYNCWAIT	Asynchronous wait 0: Disable the asynchronous wait feature 1: Enable the asynchronous wait feature
14	EXMODEN	Extended mode enable 0: Disable extended mode 1: Enable extended mode
13	NRWTEN	NWAIT signal enable For Flash memory access in burst mode, this bit enables/disables wait-state insertion via the NWAIT signal: 0: Disable NWAIT signal

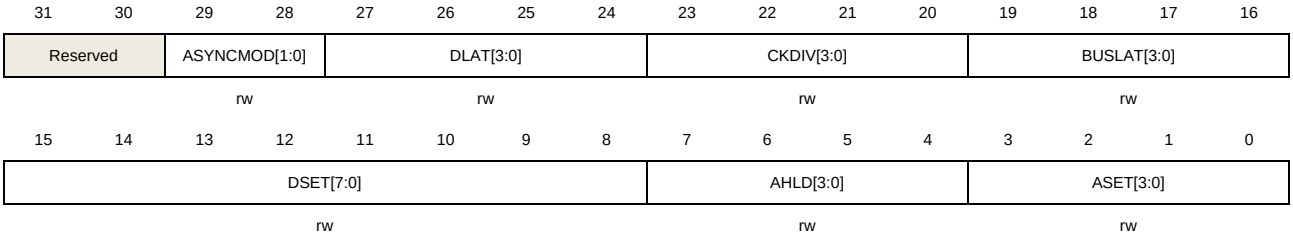
		1: Enable NWAIT signal
12	WREN	Write enable 0: Disabled write in the bank by the EXMC, otherwise an AHB error is reported 1: Enabled write in the bank by the EXMC (default after reset)
11	NRWTCFG	NWAIT signal configuration, only work in synchronous mode 0: NWAIT signal is active one data cycle before wait state 1: NWAIT signal is active during wait state
10	WRAPEN	Wrapped burst mode enable 0: Disable wrap burst mode support 1: Enable wrap burst mode support
9	NRWTPOL	NWAIT signal polarity 0: Low level is active of NWAIT 1: High level is active of NWAIT
8	SBRSTEN	Synchronous burst enable 0: Disable burst access mode 1: Enable burst access mode
7	Reserved	Must be kept at reset value.
6	NREN	NOR Flash access enable 0: Disable NOR Flash access 1: Enable NOR Flash access
5:4	NRW[1:0]	NOR bank memory data bus width 00: 8 bits 01: 16 bits(default after reset) 10/11: Reserved
3:2	NRTP[1:0]	NOR bank memory type 00: SRAM、ROM 01: PSRAM（CRAM） 10: NOR Flash 11: Reserved
1	NRMUX	NOR bank memory address/data multiplexing 0: Disable address/data multiplexing function 1: Enable address/data multiplexing function
0	NRBKEN	NOR bank enable 0: Disable the corresponding memory bank 1: Enable the corresponding memory bank

SRAM/NOR flash timing configuration registers (EXMC_SNTCFGx) (x=0, 1, 2, 3)

Address offset: 0x04 + 8 * x, (x = 0, 1, 2, and 3)

Reset value: 0x0FFF FFFF

This register has to be accessed by word(32-bit)



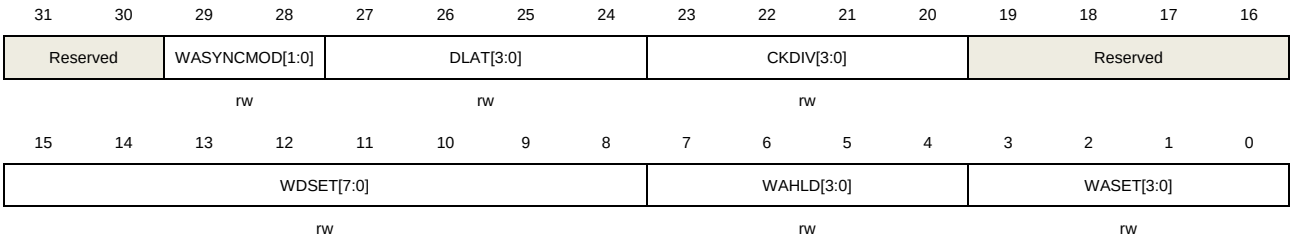
Bits	Fields	Descriptions
31:30	Reserved	Must be kept at reset value.
29:28	ASYNCMOD[1:0]	Asynchronous access mode The bits are valid only when the EXMEN bit in the EXMC_SNCTLx register is 1. 00: Mode A access 01: Mode B access 10: Mode C access 11: Mode D access
27:24	DLAT[3:0]	Data latency for NOR Flash. Only valid in synchronous access 0x0: Data latency of first burst access is 2 CLK 0x1: Data latency of first burst access is 3 CLK …… 0xF: Data latency of first burst access is 17 CLK
23:20	CKDIV[3:0]	Synchronous clock divide ratio. This filed is only effect in synchronous mode. 0x0: Reserved 0x1: EXMC_CLK period = 2 * HCLK period …… 0xF: EXMC_CLK period = 16 * HCLK period
19:16	BUSLAT[3:0]	Bus latency The bits are defined in multiplexed read mode in order to avoid bus contention, and represent the data bus to return to a high impedance state's minimum. 0x0: Bus latency = 1* HCLK period 0x1: Bus latency = 2 * HCLK period …… 0xF: Bus latency = 16 * HCLK period
15:8	DSET[7:0]	Data setup time This field is meaningful only in asynchronous access. 0x00: Reserved

		0x01: Data setup time = 2 * HCLK period …… 0xFF: Data setup time = 256 * HCLK period
7:4	AHLD[3:0]	Address hold time This field is used to set the time of address hold phase, which only used in mode D and multiplexed mode. 0x0: Reserved 0x1: Address hold time = 2 * HCLK …… 0xF: Address hold time = 16 * HCLK
3:0	ASET[3:0]	Address setup time This field is used to set the time of address setup phase. **Note:** meaningful only in asynchronous access of SRAM,ROM,NOR Flash 0x0: Address setup time = 1 * HCLK …… 0xF: Address setup time = 16 * HCLK

SRAM/NOR flash write timing configuration registers (EXMC_SNWTCFGx) (x=0, 1, 2, 3)

Address offset: 0x104 + 8 * x, (X = 0, 1, 2, and 3)
Reset value: 0x0FFF FFFF

This register is meaningful only when the EXMODEN bit in EXMC_SNCTLx is set to 1.
This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:30	Reserved	Must be kept at reset value.
29:28	WASYNCMOD[1:0]	Asynchronous access mode The bits are valid only when the EXMEN bit in the EXMC_SNCTLx register is 1. 00: Mode A access 01: Mode B access 10: Mode C access 11: Mode D access
27:24	DLAT[3:0]	Data latency for NOR Flash. Only valid in synchronous access

		0x0: Data latency of first burst access is 2 CLK 0x1: Data latency of first burst access is 3 CLK …… 0xF: Data latency of first burst access is 17 CLK
23:20	CKDIV[3:0]	Synchronous clock divide ratio. This filed is only effect in synchronous mode. 0x0: Reserved 0x1: EXMC_CLK period = 2 * HCLK period …… 0xF: EXMC_CLK period = 16 * HCLK period
19:16	Reserved	Must be kept at reset value.
15:8	WDSET[7:0]	Data setup time This field is meaningful only in asynchronous access. 0x00: Reserved 0x01: Data setup time = 2 * HCLK period …… 0xFF: Data setup time = 256 * HCLK period
7:4	WAHLD[3:0]	Address hold time This field is used to set the time of address hold phase, which only used in mode D and multiplexed mode. 0x0: Reserved 0x1: Address hold time = 2 * HCLK …… 0xF: Address hold time = 16 * HCLK
3:0	WASET[3:0]	Address setup time This field is used to set the time of address setup phase. Note: Meaningful only in asynchronous access of SRAM,ROM,NOR Flash 0x0: Address setup time = 1 * HCLK 0x1: Address setup time = 2 * HCLK …… 0xF: Address setup time = 16 * HCLK

25.4.2. NAND flash/PC card controller registers

NAND flash/PC card control registers (EXMC_NPCTLx) (x=1, 2, 3)

Address offset: 0x40 + 0x20 * x, (x = 1, 2, and 3)
Reset value: 0x0000 0018

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw			rw						rw	rw		rw	rw	rw	

Bits	Fields	Description
31:20	Reserved	Must be kept at reset value.
19:17	ECCSZ[2:0]	ECC size 000: 256 bytes 001: 512 bytes 010: 1024 bytes 011: 2048 bytes 100: 4096 bytes 101: 8192 bytes
16:13	ATR[3:0]	ALE to RE delay 0x0: ALE to RE delay = 1 * HCLK …… 0xF: ALE to RE delay = 16 * HCLK
12:9	CTR[3:0]	CLE to RE delay 0x0: CLE to RE delay = 1 * HCLK 0x1: CLE to RE delay = 2 * HCLK …… 0xF: CLE to RE delay = 16 * HCLK
8:7	Reserved	Must be kept at reset value.
6	ECCEN	ECC enable 0: Disable ECC, and reset EXMC_NECCx 1: Enable ECC
5:4	NDW[1:0]	NAND bank memory data bus width 00: 8 bits 01: 16 bits Others: Reserved **Note:** for PC/CF card, 16-bit bus width must be selected.
3	NDTP	NAND bank memory type 0: PC Card, CF card, PCMCIA 1: NAND Flash
2	NDBKEN	NAND bank enable 0: Disable corresponding memory bank 1: Enable corresponding memory bank
1	NDWTEN	Wait feature enable

		0: Disable wait feature 1: Enable wait feature
0	Reserved	Must be kept at reset value.

NAND flash/PC card interrupt enable registers (EXMC_NPINTENx) (x=1, 2, 3)

Address offset: 0x44 + 0x20 * x, (x = 1, 2, and 3)
Reset value: 0x0000 0040

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									r	rw	rw	rw	rw	rw	rw

Bits	Fields	Description
31:7	Reserved	Must be kept at reset value.
6	FFEPT	FIFO empty flag 0: FIFO is not empty. 1: FIFO is empty.
5	INTFEN	Interrupt falling edge detection enable 0: Disable interrupt falling edge detection 1: Enable interrupt falling edge detection
4	INTHEN	Interrupt high-level detection enable 0: Disable interrupt high-level detection 1: Enable interrupt high-level detection
3	INTREN	Interrupt rising edge detection enable bit 0: Disable interrupt rising edge detection 1: Enable interrupt rising edge detection
2	INTFS	Interrupt falling edge status 0: Not detect interrupt falling edge 1: Detect interrupt falling edge
1	INTHS	Interrupt high-level status 0: Not detect interrupt high-level 1: Detect interrupt high-level
0	INTRS	Interrupt rising edge status 0: Not detect interrupt rising edge

1: Detect interrupt rising edge

NAND flash/PC card common space timing configuration registers (EXMC_NPCTCFGx) (x=1, 2, 3)

Address offset: 0x48 + 0x20 * x, (x = 1, 2, and 3)
Reset value: 0xFCFC FCFC

These operations applicable to common memory space for 16-bit PC Card, CF card and NAND Flash.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
COMHIZ[7:0]								COMHLD[7:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COMWAIT[7:0]								COMSET[7:0]							
rw								rw							

Bits	Fields	Description
31:24	COMHIZ[7:0]	Common memory data bus HiZ time The bits are defined as time of bus keep high impedance state after writing the data. 0x00: COMHIZ = 1 * HCLK …… 0xFE: COMHIZ = 255 * HCLK 0xFF: COMHIZ = 256 * HCLK
23:16	COMHLD[7:0]	Common memory hold time After sending the address, the bits are defined as the address hold time. In write operation, they are also defined as the data signal hold time. 0x00: Reserved 0x01: COMHLD = 1 * HCLK …… 0xFE: COMHLD = 254 * HCLK 0xFF: COMHLD = 255 * HCLK
15:8	COMWAIT[7:0]	Common memory wait time Define the minimum time to maintain command 0x00: Reserved 0x01: COMWAIT = 2 * HCLK (+NWAIT active cycles) …… 0xFE: COMWAIT = 255 * HCLK (+NWAIT active cycles) 0xFF: COMWAIT = 256 * HCLK (+NWAIT active cycles)

7:0	COMSET[7:0]	Common memory setup time Define the time to build address before sending command 0x00: COMSET = 1 * HCLK …… 0xFE: COMSET = 255 * HCLK 0xFF: COMSET = 256 * HCLK

NAND flash/PC card attribute space timing configuration registers (EXMC_NPATCFGx) (x=1, 2, 3)

Address offset: 0x4C + 0x20 * x, (x = 1, 2, and 3)
Reset value: 0xFCFC FCFC

It is used for 8-bit accesses to the attribute memory space of the PC Card or to access the NAND Flash for the last address write access if another timing must be applied.
This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.4.3. SDRAM controller registers

SDRAM control registers (EXMC_SDCTLx) (x=0, 1)

Address offset: 0x140 + 0x04 * x, (x = 0, 1)
Reset value: 0x0000 02D0

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	PIPED[1:0]		BRSTRD	SDCLK[1:0]		WPEN	CL[1:0]		NBK	SDW[1:0]		RAW[1:0]		CAW[1:0]	
	rw		rw	rw		rw	rw		rw	rw		rw		rw	

Bits	Fields	Descriptions
31:15	Reserved	Must be kept at reset value
14:13	PIPED[1:0]	Pipeline delay These bits specify the delay for reading data after CAS latency in HCLK clock cycles. 00: 0 HCLK clock cycle delay 01: 1 HCLK clock cycle delay 10: 2 HCLK clock cycle delay 11: reserved **Note:** The corresponding bits in the EXMC_SDCTL1 register are reserved.
12	BRSTRD	Burst read When this bit is set, The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO. 0: burst read disabled 1: burst read enabled **Note:** The corresponding bits in the EXMC_SDCTL1 register are reserved.
11:10	SDCLK[1:0]	SDRAM clock configuration These bits specifies the SDRAM clock period for both SDRAM devices. The memory clock should be disabled before change, and the SDRAM memory must be re-initialized after this configuration is changed. 00: SDCLK memory clock disabled 01: Reserved 10: SDCLK memory period = 2 x HCLK periods 11: SDCLK memory period = 3 x HCLK periods Note: The corresponding bits in the EXMC_SDCTL1 register are reserved.
9	WPEN	Write protection enable This bit enables the write protection function. 0: Disable write protection, write accesses allowed 1: Enable write protection, write accesses ignored
8:7	CL[1:0]	CAS Latency This bits sets specifies SDRAM CAS latency in SDRAM memory clock cycle unit 00: reserved, do not use.

		01: 1 cycle 10: 2 cycles 11: 3 cycles
6	NBK	Number of banks This bit specifies the number of internal banks. 0: 2 internal Banks 1: 4 internal Banks
5:4	SDW[1:0]	SDRAM data bus width. These bits specify the SDRAM memory data width. 00: 8 bits 01: 16 bits 10: 32 bits 11: reserved
3:2	RAW[1:0]	Row address bit width These bits specify the bit width of a row address. 00: 11 bit 01: 12 bits 10: 13 bits 11: reserved
1:0	CAW[1:0]	Column address bit width These bits specify the bit width of column address. 00: 8 bits 01: 9 bits 10: 10 bits 11: 11 bits.

SDRAM timing configuration registers (EXMC_SDTCFGx) (x=0, 1)

Address offset: 0x148 + 0x04 * x, (x = 0, 1)

Reset value: 0x0FFF FFFF

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved				RCD[3:0]				RPD[3:0]				WRD[3:0]			
				rw				rw				rw

ARFD[3:0]				RASD[3:0]				XSRD[3:0]				LMRD[3:0]			
rw				rw				rw				rw			

Bits	Fields	Descriptions

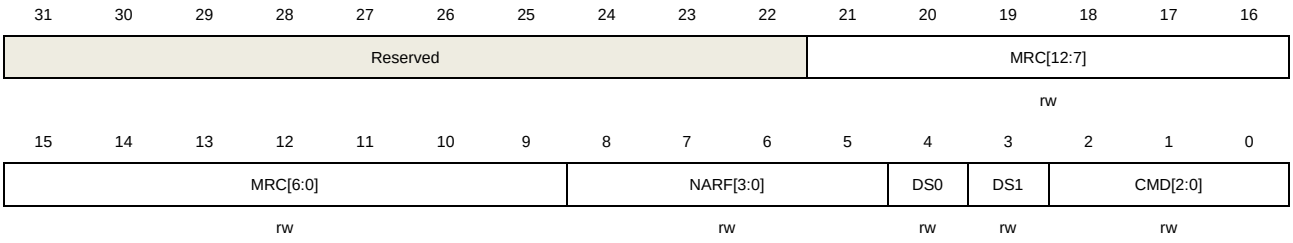
31:28	Reserved	Must be kept at reset value
27:24	RCD[3:0]	Row to column delay These bits specify the delay between an Activate command and a Read/Write command in SDRAM memory clock cycle unit. 0x0: 1 cycle. 0x1: 2 cycles .... 0xF: 16 cycles
23:20	RPD[3:0]	Row precharge delay These bits specify the delay between a Precharge command and the next command in SDRAM memory clock cycle unit. 0x0: 1 cycle 0x1: 2 cycles .... 0xF: 16 cycles Note: The corresponding bits in the EXMC_SDTR1 register are reserved. If two SDRAM memories are used, the RPD must be programmed with the timings of the slower one.
19:16	WRD[3:0]	Write recovery delay These bits specify the delay between a Write and a Precharge command in SDRAM memory clock cycle unit. 0x0: 1 cycle 0x1: 2 cycles ..... 0xF: 16 cycles Note: The corresponding bits in the EXMC_SDTR1 register are reserved. If two SDRAM memories are used, the WRD must be programmed with the timings of the slower one.
15:12	ARFD[3:0]	Auto refresh delay These bits specify the delay between two consecutive Refresh commands, the delay between two Activate commands, as well as the delay between the Refresh command and the Activate command in SDRAM memory clock cycle unit. 0x0: 1 cycle 0x1: 2 cycles .... 0xF: 16 cycles Note: The corresponding bits in the EXMC_SDTR1 register are reserved. If two SDRAM memories are used, the AFRD must be programmed with the timings of the slower one.
11:8	RASD[3:0]	Row address select delay

		These bits specify the delay between an Activate command and a Precharge command in SDRAM memory clock cycle unit. The minimum delay between two successive Self-refresh commands is also specified by these bits. 0x0: 1 cycle 0x1: 2 cycles ..... 0xF: 16 cycles
7:4	XSRD[3:0]	Exit Self-refresh delay These bits specify the delay from a Self-refresh command to an Activate command in SDRAM memory clock cycle unit. 0x0: 1 cycle 0x1: 2 cycles …… 0xF: 16 cycles
3:0	LMRD[3:0]	Load Mode Register Delay These bits specify the delay between a Load Mode Register command and a Refresh or Active command in SDRAM memory clock cycle unit. 0x0: 1 cycle 0x1: 2 cycles ..... 0xF: 16 cycles

SDRAM command register (EXMC_SDCMD)

Address offset: 0x150
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:22	Reserved	Must be kept at reset value
21:9	MRC[12:0]	Mode register content These bits specify the SDRAM Mode Register content which will be programmed when CMD = ‘100’.
8:5	NARF[3:0]	Number of successive Auto-refresh

		These bits specify how many successive Auto-refresh cycles will be send when CMD = '011'. 0x0: 1 Auto-refresh cycle 0x1: 2 Auto-refresh cycles .... 0xE: 15 Auto-refresh cycles 0xF: Reserved
4	DS0	Device select 0 This bit indicates whether the SDRAM Device0 is selected or not. 0: SDRAM Device0 is not selected 1: SDRAM Device0 is selected
3	DS1	Device select 1 This bit indicates whether the SDRAM Device1 is selected or not. 0: SDRAM Device1 is not selected 1: SDRAM Device1 is selected
2:0	CMD[2:0]	Command These bits specify the commands, which are issued to the SDRAM device. 000: Normal operation command 001: Clock enable command 010: Precharge All command 011: Auto-refresh command 100: Load Mode Register command 101: Self-refresh command 110: Power-down entry command 111: Reserved Note: At least one command device select bit (DS1 orDS0) must be set, when a command is issued. If both devices are used, the commands must be issued to the two devices by setting the DS1and DS0 bits at the same time.

SDRAM auto-refresh interval register (EXMC_SDARI)

Address offset: 0x154

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

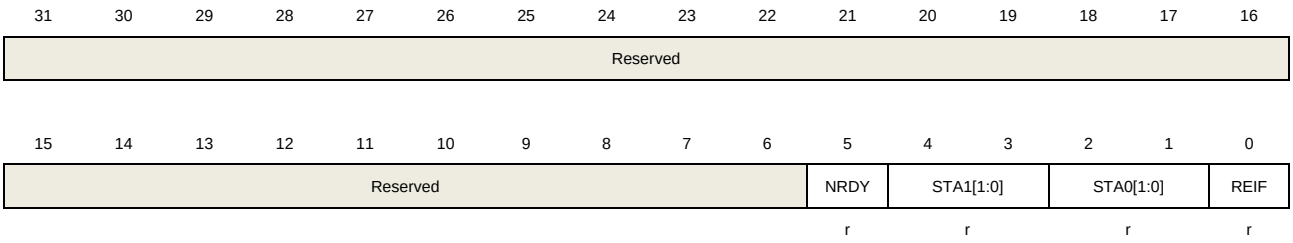
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	REIE	ARINTV[12:0]													REC
	rw	rw													w

Bits	Fields	Descriptions
31:15	Reserved	Must be kept at reset value
14	REIE	Refresh error interrupt Enable 0: Interrupt is disabled 1: An Interrupt is generated if REIF bit of the Status Register is set
13:1	ARINTV[12:0]	Auto-Refresh Interval This bit field specifies the interval of two successive auto-refresh commands in memory clock cycle unit. ARFITV = (SDRAM refresh period / Number of rows) - 20
0	REC	Refresh error flag clear The Refresh Error Flag (REIF) in the Status Register will be cleared when this bit is set. 0: no effect 1: Clear the Refresh Error flag

SDRAM status register (EXMC_SDSTAT)

Address offset: 0x158
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



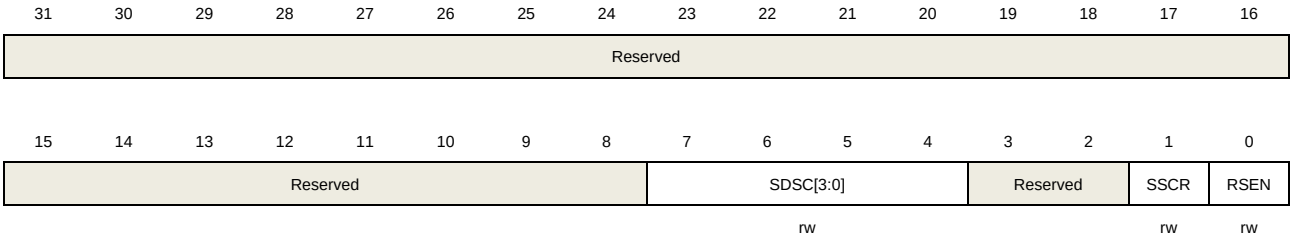
Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5	NRDY	Not Ready status This bit specifies whether the SDRAM controller is ready for a new command 0: SDRAM Controller is ready for a new command 1: SDRAM Controller is not ready for a new command
4:3	STA1[1:0]	Device1 status This bit defines the Status of SDRAM Device1. 00: Normal status 01: Self-refresh status 10: Power-down status

2:1	STA0[1:0]	Device 0 status This bit defines the Status of SDRAM Device 0. 00: Normal status 01: Self-refresh status 10: Power-down status
0	REIF	Refresh error interrupt flag 0: No refresh error 1: A refresh error occurred. An interrupt is generated when REIE = 1.

SDRAM read sample control register (EXMC_SDRSCTL)

Address offset: 0x180
Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value
7:4	SDSC[3:0]	Select the delayed sample clock of read data 0x0: Select the clock after 0 delay cell 0x1: Select the clock after 1 delay cell …… 0xF: Select the clock after 15 delay cell
3:2	Reserved	Must be kept at reset value
1	SSCR	Select sample cycle of read data 0: add 0 extra HCLK cycle to the read data sample clock besides the delay chain 1: add 1 extra HCLK cycle to the read data sample clock besides the delay chain
0	RSEN	Read sample enable 0: Read sample disabled 1: Read sample enabled

25.4.4. SQPI-PSRAM controller registers

SPI initialization register (EXMC_SINIT)

Offset address: 0x310

Reset Value: 0x1801 0000

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31:0	SIDH[63:32]	ID High Data saved for SPI Read ID Command. **Note:** SIDH[31:0] is valid when IDL=00.

26. Controller area network (CAN)

26.1. Overview

CAN bus (for Controller Area Network) is a bus standard designed to allow microcontrollers and devices to communicate with each other without a host computer.

The Basic Extended CAN, interfaces the CAN network. It supports the CAN protocols version 2.0A and 2.0B. The CAN interface handles the transmission and the reception of CAN frames fully autonomously. The CAN provides 28 scalable/configurable identifier filter banks in GD32F205 and GD32F207. The filters are used for selecting the incoming messages the software needs and discarding the others. Three transmit mailboxes are provided to the software for setting up messages. The transmission scheduler decides which mailbox has to be transmitted first. Three complete messages can be stored in each FIFO. The FIFOs are managed completely by hardware. Two receive FIFOs are used by hardware to store the incoming messages. The CAN controller also provides all hardware functions for supporting the time-triggered communication option for safety-critical applications.

26.2. Characteristics

- Supports CAN protocols version 2.0A, 2.0B
- Baud rates up to 1 Mbit/s
- Supports the time-triggered communication
- Interrupt enable and clear

Transmission

- Supports 3 transmit mailboxes
- Prioritization of messages
- Supports Time Stamp at SOF transmission

Reception

- Supports 2 receive FIFOs and each has 3 messages deep
- 28 scalable/configurable identifier filter banks in GD32F205 and GD32F207
- FIFO lock

Time-triggered communication

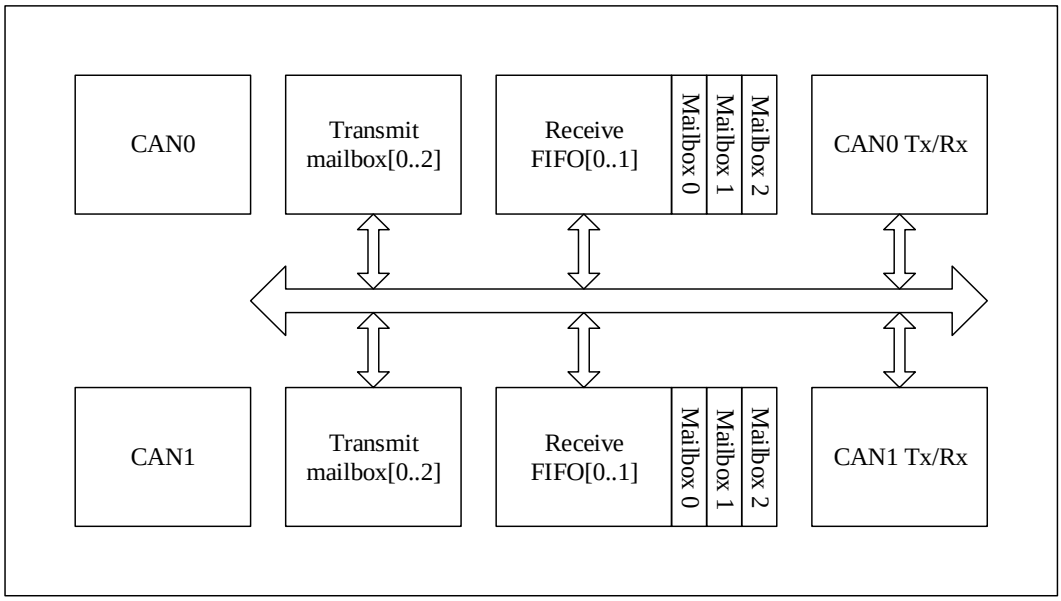
- Disable retransmission automatically
- 16-bit free timer

- Time Stamp on SOF reception
- Time Stamp sent in last two data bytes

26.3. Function overview

Figure 26-1. CAN module block diagram shows the CAN block diagram.

Figure 26-1. CAN module block diagram



26.3.1. Working mode

The CAN interface has three working modes:

- Sleep working mode.
- Initial working mode.
- Normal working mode.

Sleep working mode

Sleep working mode is the default mode after reset. In sleep working mode, the CAN is in the low-power status while the CAN clock is stopped.

When SLPWMOD bit in CAN_CTL register is set, the CAN enters the sleep working mode. Then the SLPWS bit in CAN_STAT register is set.

To leave sleep working mode automatically: the AWU bit in CAN_CTL register is set and the CAN bus activity is detected. To leave sleep working mode by software: clear the SLPWMOD bit in CAN_CTL register.

Sleep working mode to Initial working mode: Set IWMOD bit and clear SLPWMOD bit in CAN_CTL register.

Sleep working mode to Normal working mode: Clear IWMOD and SLPWMOD bit in CAN_CTL register.

Initial working mode

When the options of CAN bus communication is needed to be changed, the CAN must enter initial working mode.

When IWMOD bit in CAN_CTL register is set, the CAN enters the initial working mode. Then the IWS bit in CAN_STAT register is set.

Initial working mode to Sleep working mode: Set SLPWMOD bit and clear IWMOD bit in CAN_CTL register.

Initial working mode to Normal working mode: Clear IWMOD bit and clear SLPWMOD bit in CAN_CTL register.

Normal working mode

The CAN can enter normal working mode and to communicate with other CAN communication nodes.

To enter normal working mode: clear IWMOD and SLPWMOD bit in CAN_ CTL register.

Normal working mode to Sleep working mode: Set SLPWMOD bit in CAN_CTL register and wait the current transmission or reception completed.

Normal working mode to Initial working mode: Set IWMOD bit in CAN_CTL register, and wait the current transmission or reception completed.

26.3.2. Communication modes

The CAN interface has four communication modes:

- Silent communication mode.
- Loopback communication mode.
- Loopback and silent communication mode.
- Normal communication mode.

Silent communication mode

Silent communication mode means reception available and transmission disable.

The RX pin of the CAN can get the signal from the network and the TX pin always holds logical one.

When the SCMOD bit in CAN_BT register is set, the CAN enters the silent communication mode. When it is cleared, the CAN leaves silent communication mode.

Silent communication mode is useful on monitoring the network messages.

Loopback communication mode

Loopback communication mode means the sending messages are transferred into the reception FIFOs, the RX pin is disconnected from the CAN network and the TX pin can send messages to the CAN network.

Set LCMOD bit in CAN_BT register to enter loopback communication mode or clear it to leave. Loopback communication mode is useful on self-test.

Loopback and silent communication mode

Loopback and silent communication mode means the RX and TX pins are disconnected from the CAN network while the sending messages are transferred into the reception FIFOs.

Set LCMOD and SCMOD bit in CAN_BT register to enter loopback and silent communication mode or clear them to leave.

Loopback and silent communication mode is useful on self-test. The TX pin holds logical one. The RX pin holds high impedance state.

Normal communication mode

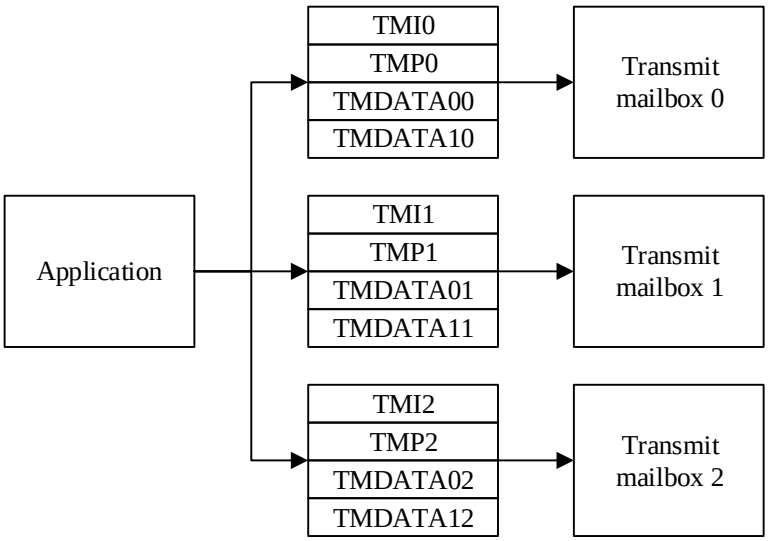
Normal communication mode is the default communication mode unless the LCMOD or SCMOD bit in CAN_BT register is set.

26.3.3. Data transmission

Transmission register

Three transmit mailboxes are transparent to the application. You can use transmit mailboxes through four transmission registers: CAN_TMIx, CAN_TMPx, CAN_TMDATA0x and CAN_TMDATA1x. As shown in ***Figure 26-2. Transmission register***.

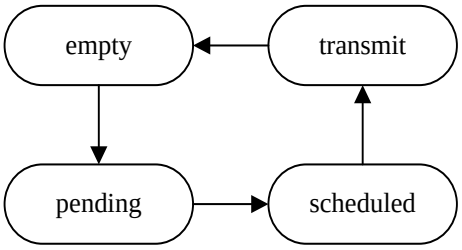
Figure 26-2. Transmission register



Transmit mailbox state

A transmit mailbox can be used when it is free: empty state. If the data is filled in the mailbox, setting TEN bit in CAN_TMIx register to prepare for starting the transmission: pending state. If more than one mailbox is in the pending state, they need schedule the transmission: scheduled state. A mailbox with priority enter transmit state and start transmitting the message. After the message has been sent, the mailbox is free: empty state. As shown in *Figure 26-3. State of transmission mailbox*.

Figure 26-3. State of transmission mailbox



Transmit status and error

The CAN_TSTAT register includes the transmit status and error bits: MTF, MTFNERR, MAL, MTE.

- MTF: mailbox transmits finished. Typically, MTF is set when the frame in the transmit mailbox has been sent.
- MTFNERR: mailbox transmits finished and no error. MTFNERR is set when the frame in the transmission mailbox has been sent without any error.
- MAL: mailbox arbitration lost. MAL is set while the frame transmission is failed because of the arbitration lost.
- MTE: mailbox transmits error. MTE is set while the frame transmission is failed because of the detection error of CAN bus.

Steps of sending a frame

To send a frame through the CAN:
Step 1: Select one free transmit mailbox.
Step 2: Fill four transmission registers with the application's acquirement.
Step 3: Set TEN bit in CAN_TMIx register.
Step 4: Check the transmit status. Typically, MTF and MTFNERR are set if transmission is successful.

Transmission options

Abort

MST bit in CAN_TSTAT register can abort the transmission.

If the transmission mailbox's state is pending or scheduled, the abort of transmission can be

done immediately.

In the state of transmit, the abort of transmission does not take effect immediately until the transmission is finished. In case of transmission successful, the MTFNERR and MTF in CAN_TSTAT are set and state changes to empty. In case of transmission failed, the state changes to be scheduled and then the abort of transmission can be done immediately.

Priority

When more than one transmit mailbox is pending, the transmission order is given by the TFO bit in CAN_CTL register.

In case TFO is 1, the three transmit mailboxes work as FIFO.

In case TFO is 0, the transmit mailbox with lowest identifier has the highest priority of transmission. If the identifiers are equal, the lower mailbox number will be scheduled first.

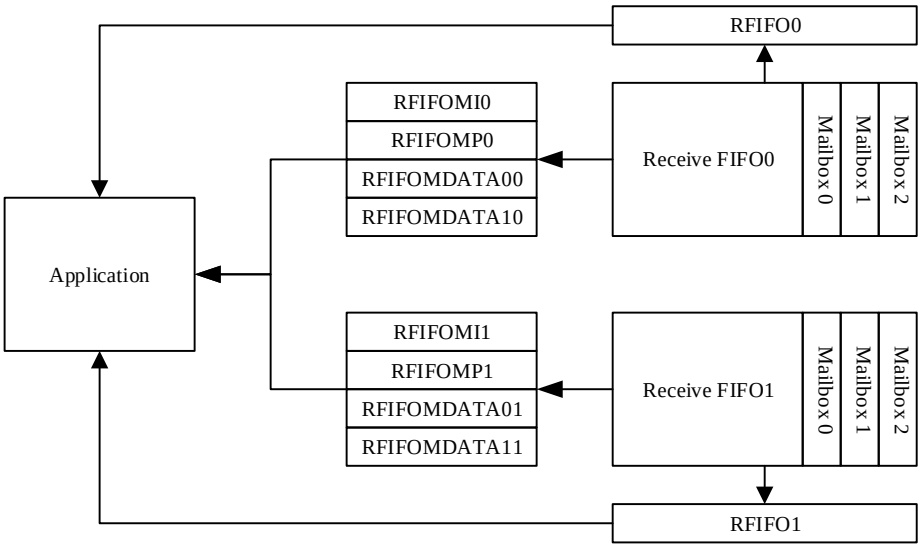
26.3.4. Data reception

Reception register

Two receive FIFOs are transparent to the application. You can use receive FIFOs through five registers: CAN_RFIFOx, CAN_RFIFOMIx, CAN_RFIFOMPx, CAN_RFIFOMDATA0x and CAN_RFIFOMDATA1x. FIFO's status and operation can be handled by CAN_RFIFOx register. Reception frame data can be achieved through the registers: CAN_RFIFOMIx, CAN_RFIFOMPx, CAN_RFIFOMDATA0x and CAN_RFIFOMDATA1x.

Each FIFO consists of three receive mailboxes. As shown in ***Figure 26-4. Reception register***.

Figure 26-4. Reception register



Receive FIFO

Receive FIFO has three mailboxes. The reception frames are stored in the mailbox ordered

by the arriving sequence of the frames. First arrived frame can be accessed by application firstly.

The number of frames in the receive FIFO and the status can be accessed by the register CAN_RFIFO0 and CAN_RFIFO1.If at least one frame has been stored in the receive FIFO0. The frame data is placed in the registers (CAN_RFIFOMI0, CAN_RFIFOMP0, CAN_RFIFOMDATA00, CAN_RFIFOMDATA10). After reading the current frame, set RFD0 bit in CAN_RFIFO0 to release a frame in the receive FIFO and the software can read the next frame.

Receive FIFO status

RFLx bit in CAN_RFIFOx register: receive FIFO length. It is 0 when no frame is stored in the reception FIFO and 3 when FIFOx is full.

RFFx bit in CAN_RFIFOx register: the FIFO holds three frames. It indicates FIFOx is full.

RFOx bit in CAN_RFIFOx register: one new frame arrived while the FIFO has hold three frames. It indicates FIFOx is overfull. If the RFOD bit in CAN_CTL register is set, the new frame is discarded. If the RFOD bit in CAN_CTL register is reset, the new frame is stored into the receive FIFO and the last frame in the receive FIFO is discarded.

Steps of receiving a message

Step 1: Check the number of frames in the receive FIFO.

Step 2: Reading CAN_RFIFOMIx, CAN_RFIFOMPx, CAN_RFIFOMDATA0x and CAN_RFIFOMDATA1x if there is data pending.

Step 3: Set the RFDx bit in CAN_RFIFOx register.

26.3.5. Filtering function

The CAN would receive frames from the CAN bus. If the frame is passed through the filter, it is stored into the receive FIFOs. Otherwise, the frame will be discarded without intervention by the software.

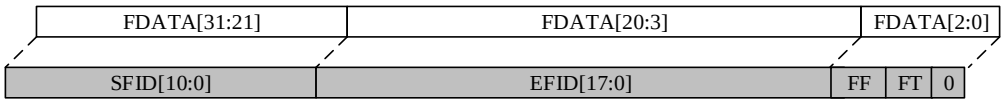
The identifier of frame from the CAN bus takes part in the matching of the filter.

Scale

In GD32F205 and GD32F207, the filter consists of 28 banks: bank0 to bank27. Each bank has two 32-bit registers: CAN_FxDATA0 and CAN_FxDATA1.Each filter bank can be configured to 32-bit or 16-bit.

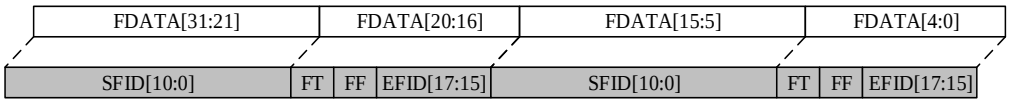
32-bit: SFID[10:0], EFID[17:0], FF and FT bits. As shown in ***Figure 26-5. 32-bit filter***.

Figure 26-5. 32-bit filter



16-bit: SFID [10:0], FT, FF and EFID[17:15] bits. As shown in ***Figure 26-6. 16-bit filter***.

Figure 26-6. 16-bit filter



Mask mode

In mask mode the identifier registers are associated with mask registers specifying which bits of the identifier are handled as “must match” (when the bit in mask register is ‘1’) or as “don’t care” (when the bit in mask register is ‘0’).

32-bit mask mode example is shown in ***Figure 26-7. 32-bit mask mode filter***.

Figure 26-7. 32-bit mask mode filter

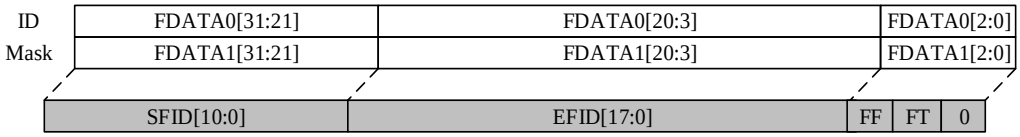


Figure 26-8. 16-bit mask mode filter

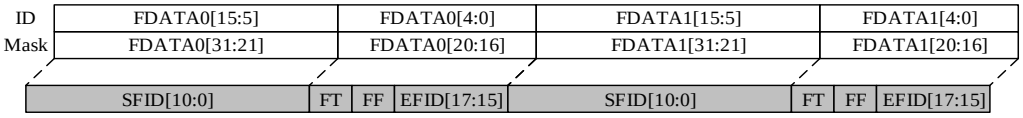

List mode

The filter consists of frame identifiers. The filter can decide whether a frame will be discarded or not. When one frame arrived, the filter will check which member can match the identifier of the frame.

32-bit list mode example is shown in ***Figure 26-9. 32-bit list mode filter***.

Figure 26-9. 32-bit list mode filter

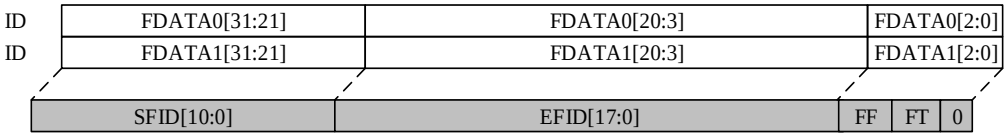

Figure 26-10. 16-bit list mode filter

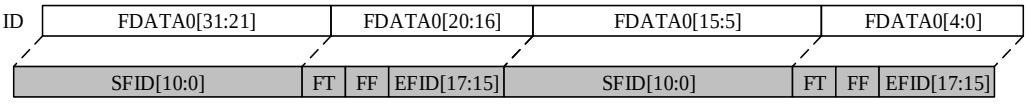


Filter number

Each filter within a filter bank is numbered from 0 to a maximum dependent on the mode and the scale of each of the filter banks.For example, there are two filter banks. Bank 0 is configured as 32-bit mask mode. Bank 1 is configured as 32-bit list mode. The filter number is shown in ***Table 26-1. 32-bit filter number***.

Table 26-1. 32-bit filter number

Filter Bank	Filter Data Register	Filter Number
0	F0DATA0-32bit-ID	0
	F0DATA1-32bit-Mask	
1	F1DATA0-32bit-ID	1
	F1DATA1-32bit-ID	2

Associated FIFO

28 banks can be associated with FIFO0 or FIFO1. If the bank is associated with FIFO0, the frames passed through the bank will fill the FIFO0.

Active

The filter bank needs to be configured activation if the application wants the bank working and while filters not used by the application should be left deactivated.

Filtering index

Each filter number corresponds to a filtering rule. When the frame from the CAN bus passes the filters, a filter number must associate with the frame. The filter number is called filtering index. It stores in the FI bits in CAN_RFIFOMPx when the frame is read by the application.

Each FIFO numbers the filters within the banks associated with the FIFO itself whether the bank is active or not.

The example about filtering index is shown in ***Table 26-2. Filtering index***.

Table 26-2. Filtering index

Filter Bank	FIFO0	Active	Filter Nunber	Filter Bank	FIFO1	Active	Filter Nunber
0	F0DATA0-32bit-ID	Yes	0	2	F2DATA0[15:0]-16bit-ID	Yes	0
	F0DATA1-32bit-Mask				F2DATA0[32:16]-16bit-Mask		
1	F1DATA0-32bit-ID	Yes	1		F2DATA1[15:0]-16bit-ID		1
	F1DATA1-32bit-ID		2		F2DATA1[32:16]-16bit-Mask		

Filter Bank	FIFO0	Active	Filter Nunber	Filter Bank	FIFO1	Active	Filter Nunber
3	F3DATA0[15:0]-16bit-ID	No	3	4	F4DATA0-32bit-ID	No	2
	F3DATA0[32:16]-16bit-Mask				F4DATA1-32bit-Mask		
	F3DATA1[15:0]-16bit-ID		4	5	F5DATA0-32bit-ID	No	3
	F3DATA1[32:16]-16bit-Mask				F5DATA1-32bit-ID		4
7	F7DATA0[15:0]-16bit-ID	No	5	6	F6DATA0[15:0]-16bit-ID	Yes	5
	F7DATA0[32:16]-16bit-Mask		6		F6DATA0[32:16]-16bit-Mask		6
	F7DATA1[15:0]-16bit-ID		7		F6DATA1[15:0]-16bit-ID		7
	F7DATA1[32:16]-16bit-Mask		8		F6DATA1[32:16]-16bit-Mask		8
8	F8DATA0[15:0]-16bit-ID	Yes	9	10	F10DATA0[15:0]-16bit-ID	No	9
	F8DATA0[32:16]-16bit-Mask		10		F10DATA0[32:16]-16bit-Mask		
	F8DATA1[15:0]-16bit-ID		11		F10DATA1[15:0]-16bit-ID		10
	F8DATA1[32:16]-16bit-Mask		12		F10DATA1[32:16]-16bit-Mask		
9	F9DATA0[15:0]-16bit-ID	Yes	13	11	F11DATA0[15:0]-16bit-ID	No	11
	F9DATA0[32:16]-16bit-Mask				F11DATA0[32:16]-16bit-Mask		12
	F9DATA1[15:0]-16bit-ID		14		F11DATA1[15:0]-16bit-ID		13
	F9DATA1[32:16]-16bit-Mask				F11DATA1[32:16]-16bit-Mask		14
12	F12DATA0-32bit-ID	Yes	15	13	F13DATA0-32bit-ID	Yes	15
	F12DATA1-32bit-Mask				F13DATA1-32bit-Mask		16

Priority

The filters have the priority:

1. 32-bit mode is higher than 16-bit mode.
2. List mode is higher than mask mode.
3. Smaller filter index value has the higher priority.

26.3.6. Time-triggered communication

The time-triggered CAN protocol is a higher layer protocol on top of the CAN data link layer. Time-triggered communication means that activities are triggered by the elapsing of time segments. In a time-triggered communication system all points of time of message transmission are defined during the development of a system. A time-triggered communication system is ideal for applications in which the data traffic is of a periodic nature.

In this mode, the 16-bit internal counter of the CAN hardware is activated and used to generate the time stamp value stored in the CAN_RFIFOMPx and CAN_TMPx registers for reception and transmission respectively. The internal counter is incremented each CAN bit time. The internal counter is captured on the sample point of the SOF (Start of Frame) bit in both reception and transmission.

The automatic retransmission is disabled in the time-triggered CAN communication.

26.3.7. Communication parameters

Nonautomatic retransmission mode

This mode has been implemented in order to fulfill the requirement of the time-triggered communication option of the CAN standard. To configure the hardware in this mode the ARD bit in the CAN_CTL register must be set.

In this mode, each transmission is started only once. If the first attempt fails, due to an arbitration loss or an error, the hardware will not automatically restart the frame transmission.

At the end of the first transmission attempt, the hardware considers the request as finished and sets the MTF bit in the CAN_TSTAT register. The result of the transmission is indicated in the CAN_TSTAT register by the MTFNERR, MAL and MTE bits.

Bit time

On the bit-level the CAN protocol uses synchronous bit transmission. This not only enhances the transmitting capacity but also means that a sophisticated method of bit synchronization is required. While bit synchronization in a character-oriented transmission (asynchronous) is performed upon the reception of the start bit available with each character, a synchronous transmission protocol there is just one start bit available at the beginning of a frame. To ensure the receiver to correctly read the messages, continuous resynchronization is required. Phase buffer segments are therefore inserted before and after the nominal sample point within a bit interval.

The CAN protocol regulates bus access by bit-wise arbitration. The signal propagation from sender to receiver and back to the sender must be completed within one bit-time. For synchronization purposes a further time segment, the propagation delay segment, is needed in addition to the time reserved for synchronization, the phase buffer segments. The

propagation delay segment takes into account the signal propagation on the bus as well as signal delays caused by transmitting and receiving nodes.

The normal bit time simplified by the CAN from the CAN protocol has three segments as follows:

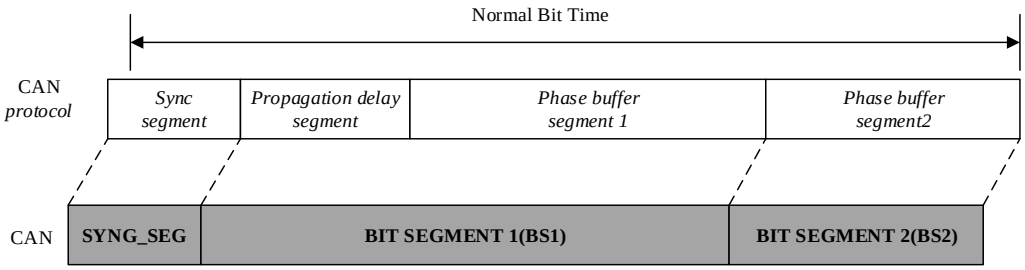
Synchronization segment (SYNC_SEG): a bit change is expected to occur within this time segment. It has a fixed length of one time quantum ($1 \times t_{CAN}$).

Bit segment 1 (BS1): defines the location of the sample point. It includes the *Propagation delay segment* and *Phase buffer segment 1* of the CAN standard. Its duration is programmable between 1 and 16 time quanta but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.

Bit segment 2 (BS2): defines the location of the transmit point. It represents the *Phase buffer segment 2* of the CAN standard. Its duration is programmable between 1 and 8 time quanta but may also be automatically shortened to compensate for negative phase drifts.

The bit time is shown as in the ***Figure 26-11. The bit time***.

Figure 26-11. The bit time



The resynchronization Jump Width (SJW) defines an upper bound to the amount of lengthening or shortening of the bit segments. It is programmable between 1 and 4 time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

Baud rate

The CAN's clock derives from the APB1 bus. The CAN calculates its baud rate as follow:

$$\text{BaudRate} = \frac{1}{\text{Normal Bit Time}} \quad (26\text{-}1)$$

$$Normal\ Bit\ Time = t_{SYNC\_SEG} + t_{BS1} + t_{BS2}$$

with:

$$t_{SYNC\_SEG} = 1 \times t_{CAN}$$

$$t_{BS1} = (1 + BT.BS1) \times t_{CAN}$$

$$t_{BS2} = (1 + BT.BS2) \times t_{CAN}$$

$$t_{CAN} = (1 + BT.BRP) \times t_{PCLK1}$$

26.3.8. Error flags

The error management as described in the CAN protocol is handled entirely by hardware using a Transmit Error Counter (TECNT value, in CAN_ERR register) and a Receive Error Counter (RECNT value, in the CAN_ERR register), which get incremented or decremented according to the error condition. For detailed information about TECNT and RECNT management, please refer to the CAN standard.

Both of them may be read by software to determine the stability of the network.

Furthermore, the CAN hardware provides detailed information on the current error status in CAN_ERR register. By means of the CAN_INTEN register (ERRIE bit, etc.), the software can configure the interrupt generation on error detection in a very flexible way.

Bus-Off recovery

The Bus-Off state is reached when TECNT is greater than 255. This state is indicated by BOERR bit in CAN_ERR register. In Bus-Off state, the CAN is no longer able to transmit and receive messages.

Depending on the ABOR bit in the CAN_CTL register, CAN will recover from Bus-Off (becomes error active again) either automatically or on software request. But in both cases the CAN has to wait at least for the recovery sequence specified in the CAN standard (128 occurrences of 11 consecutive recessive bits monitored on CAN RX).

If ABOR is set, the CAN will start the recovering sequence automatically after it has entered Bus-Off state.

If ABOR is cleared, the software must initiate the recovering sequence by requesting CAN to enter and to leave initialization mode.

26.3.9. CAN interrupts

Four interrupt vectors are dedicated to CAN. Each interrupt source can be independently enabled or disabled by setting or resetting related bits in CAN_INTEN.

The interrupt sources can be classified into:

- transmit interrupt
- FIFO0 interrupt
- FIFO1 interrupt
- error and status change interrupt

Transmit interrupt

The transmit interrupt can be generated by any of the following conditions and TMEIE bit in CAN_INTEN register will be set:

- TX mailbox 0 transmit finished: MTF0 bit in the CAN_TSTAT register is set.
- TX mailbox 1 transmit finished: MTF1 bit in the CAN_TSTAT register is set.
- TX mailbox 2 transmit finished: MTF2 bit in the CAN_TSTAT register is set.

Receive FIFO0 interrupt

The Receive FIFO0 interrupt can be generated by the following conditions:

- Reception FIFO0 not empty: RFL0 bits in the CAN_RFIFO0 register are not ‘00’ and RFNEIE0 in CAN_INTEN register is set.
- Reception FIFO0 full: RFF0 bit in the CAN_RFIFO0 register is set and RFFIE0 in CAN_INTEN register is set.
- Reception FIFO0 overrun: RFO0 bit in the CAN_RFIFO0 register is set and RFOIE0 in CAN_INTEN register is set.

Receive FIFO1 interrupt

The Receive FIFO1 interrupt can be generated by the following conditions:

- Reception FIFO1 not empty: RFL1 bits in the CAN_RFIFO1 register are not ‘00’ and RFNEIE1 in CAN_INTEN register is set.
- Reception FIFO1 full: RFF1 bit in the CAN_RFIFO1 register is set and RFFIE1 in CAN_INTEN register is set.
- Reception FIFO1 overrun: RFO1 bit in the CAN_RFIFO1 register is set and RFOIE1 in CAN_INTEN register is set.

Error and working mode change interrupt

The error and working mode change interrupt can be generated by the following conditions:

- Error: ERRIF bit in the CAN_STAT register and ERRIE bit in the CAN_INTEN register are set. Refer to ERRIF description in the CAN_STAT register.

- Wakeup: WUIF bit in the CAN_STAT register is set and WIE bit in the CAN_INTEN register is set.
- Enter sleep working mode: SLPIF bit in the CAN_STAT register is set and SLPWIE bit in the CAN_INTEN register is set.

26.4. Register definition

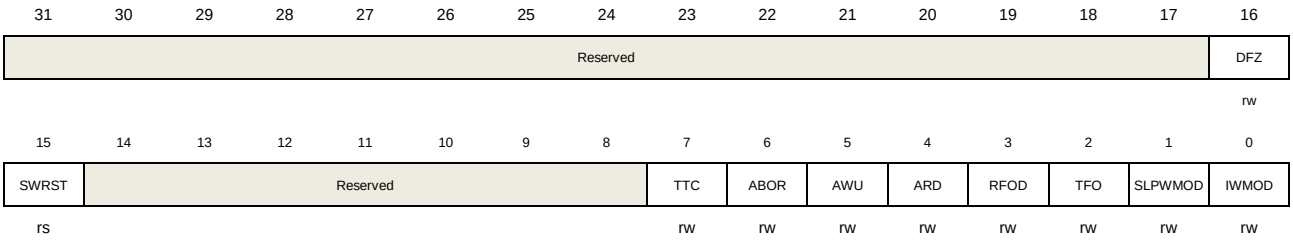
CAN0 start address: 0x4000 6400

CAN1 start address: 0x4000 6800

26.4.1. Control register (CAN_CTL)

Address offset: 0x00
Reset value: 0x0001 0002

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:17	Reserved	Must be kept at reset value
16	DFZ	Debug freeze If the CANx_HOLD in DBG_CTL0 register is set, this bit defines the CAN stops for debug or works normal. If the CANx_HOLD in DBG_CTL0 register is cleared, this bit takes no effect. 0: CAN reception and transmission works normal even during debug 1: CAN reception and transmission stops working during debug
15	SWRST	Software reset 0: No effect 1: Reset CAN with working mode of sleep. This bit is automatically reset to 0
14:8	Reserved	Must be kept at reset value
7	TTC	Time-triggered communication 0: Disable time-triggered communication 1: Enable time-triggered communication
6	ABOR	Automatic bus-off recovery 0: The bus-off state is left manually by software 1: The bus-off state is left automatically by hardware
5	AWU	Automatic wakeup If this bit is set, the sleep mode left when CAN bus activity detected, and SLPWMOD bit in CAN_CTL register will be cleared automatically.

		0: The sleeping working mode is left manually by software 1: The sleeping working mode is left automatically by hardware
4	ARD	Automatic retransmission disable 0: Enable Automatic retransmission 1: Disable Automatic retransmission
3	RFOD	Receive FIFO overwrite disable 0: Enable receive FIFO overwrite when the receive FIFO is full and overwrite the FIFO with the incoming frame 1: Disable receive FIFO overwrite when the receive FIFO is full and discard the incoming frame
2	TFO	Transmit FIFO order 0: Order with the identifier of the frame 1: Order with first in and first out
1	SLPWMOD	Sleep working mode If this bit is set by software, the CAN enters sleep working mode after the current transmission or reception completed. This bit can cleared by software or hardware. If AWU bit in CAN_CTL register is set, this bit is cleared by hardware when CAN bus activity detected. 0: Disable sleep working mode 1: Enable sleep working mode
0	IWMOD	Initial working mode 0: Disable initial working mode 1: Enable initial working mode

26.4.2. Status register (CAN_STAT)

Address offset: 0x04

Reset value: 0x0000 0C02

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				RXL	LASTRX	RS	TS	Reserved			SLPIF	WUIF	ERRIF	SLPWS	IWS
				r	r	r	r				rc_w1	rc_w1	rc_w1	r	r

Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value

11	RXL	RX level
10	LASTRX	Last sample value of RX pin
9	RS	Receiving state 0: CAN is not working in the receiving state 1: CAN is working in the receiving state
8	TS	Transmitting state 0: CAN is not working in the transmitting state 1: CAN is working in the transmitting state
7:5	Reserved	Must be kept at reset value
4	SLPIF	Status change interrupt flag of sleep working mode entering This bit is set by hardware when entering sleep working mode, and cleared by hardware when the CAN is not in sleep working mode. This bit can also be cleared by software when writing 1 to this bit. 0: CAN is not entering the sleep working mode 1: CAN is entering the sleep working mode
3	WUIF	Status change interrupt flag of wakeup from sleep working mode This bit is set when CAN bus activity is detected in sleep working mode. This bit can be cleared by software when writing 1 to this bit. 0: Wakeup event is not coming 1: Wakeup event is coming
2	ERRIF	Error interrupt flag This bit is set by following event. The BOERR bit in CAN_ERR register is set and BOIE bit in CAN_INTEN register is set. Or the PERR bit in CAN_ERR register is set and PERRIE bit in CAN_INTEN register is set. Or the WERR bit in CAN_ERR register is set and WERRIE bit in CAN_INTEN register is set. Or the ERRN bits in CAN_ERR register are set to 1 to 6 (not 0 and not 7) and ERRNIE in CAN_INTEN register is set. This bit is cleared by software when writing 1 to this bit. 0: No error interrupt flag 1: Any error interrupt flag has happened
1	SLPWS	Sleep working state This bit is set by hardware when the CAN enters sleep working mode after setting SLPWMOD bit in CAN_CTL register. If the CAN leaves from normal working mode to sleep working mode, it must wait the current frame transmission or reception completed. This bit is cleared by hardware when the CAN leaves sleep working mode. Clear SLPWMOD bit in CAN_CTL register or automatically detect the CAN bus activity when AWU bit is set in CAN_CTL register. If CAN leaves sleep working mode to normal working mode, this bit will be cleared after receiving 11 consecutive recessive bits from the CAN bus. 0: CAN is not the state of sleep working mode

1: CAN is the state of sleep working mode

0	IWS	Initial working state This bit is set by hardware when the CAN enters initial working mode after setting IWMOD bit in CAN_CTL register. If the CAN leaves from normal working mode to initialize working mode, it must wait the current frame transmission or reception completed. This bit is cleared by hardware when the CAN leave initial working mode after clearing IWMOD bit in CAN_CTL register. If CAN leaves initial working mode to normal working mode, this bit will be cleared after receiving 11 consecutive recessive bits from the CAN bus. 0: CAN is not the state of initial working mode 1: CAN is the state of initial working mode

26.4.3. Transmit status register (CAN_TSTAT)

Address offset: 0x08

Reset value: 0x1C00 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TMLS2	TMLS1	TMLS0	TME2	TME1	TME0	NUM[1:0]		MST2	Reserved			MTE2	MAL2	MTFNERR2	MTF2
r	r	r	r	r	r	r		rs				rc_w1	rc_w1	rc_w1	rc_w1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MST1	Reserved			MTE1	MAL1	MTFNERR1	MTF1	MST0	Reserved			MTE0	MAL0	MTFNERR0	MTF0
rs				rc_w1	rc_w1	rc_w1	rc_w1	rs				rc_w1	rc_w1	rc_w1	rc_w1

Bits	Fields	Descriptions
31	TMLS2	Transmit mailbox 2 last sending in transmit FIFO This bit is set by hardware when transmit mailbox 2 has the last sending order in the transmit FIFO with at least two frames are pending.
30	TMLS1	Transmit mailbox 1 last sending in transmit FIFO This bit is set by hardware when transmit mailbox 1 has the last sending order in the transmit FIFO with at least two frames are pending.
29	TMLS0	Transmit mailbox 0 last sending in transmit FIFO This bit is set by hardware when transmit mailbox 0 has the last sending order in the transmit FIFO with at least two frames are pending.
28	TME2	Transmit mailbox 2 empty 0: Transmit mailbox 2 not empty 1: Transmit mailbox 2 empty

27	TME1	Transmit mailbox 1 empty 0: Transmit mailbox 1 not empty 1: Transmit mailbox 1 empty
26	TME0	Transmit mailbox 0 empty 0: Transmit mailbox 0 not empty 1: Transmit mailbox 0 empty
25:24	NUM[1:0]	These bits are the number of the transmit FIFO mailbox in which the frame will be transmitted if at least one mailbox is empty. These bits are the number of the transmit FIFO mailbox in which the frame will be transmitted lastly if all mailboxes are full.
23	MST2	Mailbox 2 stop transmitting This bit is set by the software to stop mailbox 2 transmitting. This bit is reset by the hardware while the mailbox 2 is empty.
22:20	Reserved	Must be kept at reset value
19	MTE2	Mailbox 2 transmit error This bit is set by hardware while the transmit error is occurred. This bit is reset by software when writing 1 to this bit or MTF2 bit in CAN_TSTAT register. This bit is reset by hardware when next transmission starts.
18	MAL2	Mailbox 2 arbitration lost This bit is set while the arbitration lost is occurred. This bit is reset by software when writing 1 to this bit or MTF2 bit in CAN_TSTAT register. This bit is reset by hardware when next transmission starts.
17	MTFNERR2	Mailbox 2 transmit finished and no error This bit is set when the transmission finished and no error. This bit is reset by software when writing 1 to this bit or MTF2 bit in CAN_TSTAT register. This bit is reset by hardware when the transmission finished with error. 0: Mailbox 2 transmit finished with error 1: Mailbox 2 transmit finished and no error
16	MTF2	Mailbox 2 transmit finished This bit set by hardware when the transmission finish or abort. This bit is reset by software when write 1 to this bit or TEN bit in CAN_TMI2 is 1. 0: Mailbox 2 transmit is progressing 1: Mailbox 2 transmit finished
15	MST1	Mailbox 1 stop transmitting This bit is set by the software to stop mailbox 1 transmitting. This bit is reset by the hardware while the mailbox 1 is empty.
14:12	Reserved	Must be kept at reset value
11	MTE1	Mailbox 1 transmit error

		This bit is set by hardware while the transmit error is occurred. This bit is reset by software when writing 1 to this bit or MTF1 bit in CAN_TSTAT register. This bit is reset by hardware when next transmission starts.
10	MAL1	Mailbox 1 arbitration lost This bit is set while the arbitration lost is occurred. This bit reset by software when write 1 to this bit or MTF1 bit in CAN_TSTAT register. This bit reset by hardware when next transmission starts.
9	MTFNERR1	Mailbox 1 transmit finished and no error This bit is set when the transmission finished and no error. This bit reset by software when write 1 to this bit or MTF1 bit in CAN_TSTAT register. This bit reset by hardware when the transmission finished with error. 0: Mailbox 1 transmit finished with error 1: Mailbox 1 transmit finished and no error
8	MTF1	Mailbox 1 transmit finished This bit is set by hardware when the transmission finish or abort. This bit reset by software when write 1 to this bit or TEN bit in CAN_TMI1 is 1. 0: Mailbox 1 transmit is progressing 1: Mailbox 1 transmit finished
7	MST0	Mailbox 0 stop transmitting This bit is set by the software to stop mailbox 0 transmitting. This bit is reset by the hardware while the mailbox 0 is empty.
6:4	Reserved	Must be kept at reset value
3	MTE0	Mailbox 0 transmit error This bit is set by hardware while the transmit error is occurred. This bit reset by software when write 1 to this bit or MTF0 bit in CAN_TSTAT register. This bit reset by hardware when next transmission starts.
2	MAL0	Mailbox 0 arbitration lost This bit is set while the arbitration lost is occurred. This bit reset by software when write 1 to this bit or MTF0 bit in CAN_TSTAT register. This bit reset by hardware when next transmission starts.
1	MTFNERR0	Mailbox 0 transmit finished and no error This bit is set when the transmission finished and no error. This bit reset by software when write 1 to this bit or MTF0 bit in CAN_TSTAT register. This bit reset by hardware when the transmission finished with error. 0: Mailbox 0 transmit finished with error 1: Mailbox 0 transmit finished and no error
0	MTF0	Mailbox 0 transmit finished This bit is set by hardware when the transmission finish or abort. This bit reset by software when write 1 to this bit or TEN bit in CAN_TMI0 is 1.

0: Mailbox 0 transmit is progressing

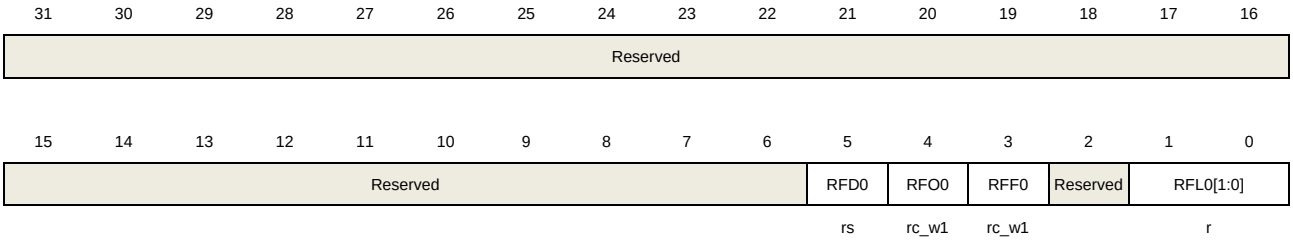
1: Mailbox 0 transmit finished

26.4.4. Receive message FIFO0 register (CAN_RFIFO0)

Address offset: 0x0C

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5	RFD0	Receive FIFO0 dequeue This bit is set by the software to start dequeuing a frame from receive FIFO0. This bit is reset by the hardware while the dequeuing is done.
4	RFO0	Receive FIFO0 overfull This bit is set by hardware when receive FIFO0 is overfull and reset by software when writing 1 to this bit. 0: The receive FIFO0 is not overfull 1: The receive FIFO0 is overfull
3	RFF0	Receive FIFO0 full This bit is set by hardware when receive FIFO0 is full and reset by software when writing 1 to this bit. 0: The receive FIFO0 is not full 1: The receive FIFO0 is full
2	Reserved	Must be kept at reset value
1:0	RFL0[1:0]	Receive FIFO0 length These bits are the length of the receive FIFO0.

26.4.5. Receive message FIFO1 register (CAN_RFIFO1)

Address offset: 0x10

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										RFD1	RFO1	RFF1	Reserved	RFL1[1:0]	
										rs	rc_w0	rc_w1		r	

Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5	RFD1	Receive FIFO1 dequeue This bit is set by the software to start dequeuing a frame from receive FIFO1. This bit is reset by the hardware while the dequeuing is done.
4	RFO1	Receive FIFO1 overfull This bit is set by hardware when receive FIFO1 is overfull and reset by software when write 0 to this bit. 0: The receive FIFO1 is not overfull 1: The receive FIFO1 is overfull
3	RFF1	Receive FIFO1 full This bit is set by hardware when receive FIFO1 is full and reset by software when write 1 to this bit. 0: The receive FIFO1 is not full 1: The receive FIFO1 is full
2	Reserved	Must be kept at reset value
1:0	RFL1[1:0]	Receive FIFO1 length These bits are the length of the receive FIFO1.

26.4.6. Interrupt enable register (CAN_INTEN)

Address offset: 0x14

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved														SLPWIE	WIE
														rw	rw

rw				rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits	Fields	Descriptions
31:18	Reserved	Must be kept at reset value
17	SLPWIE	Sleep working interrupt enable 0: Sleep working interrupt disable 1: Sleep working interrupt enable
16	WIE	Wakeup interrupt enable 0: Wakeup interrupt disable 1: Wakeup interrupt enable
15	ERRIE	Error interrupt enable 0: Error interrupt disable 1: Error interrupt enable
14:12	Reserved	Must be kept at reset value
11	ERRNIE	Error number interrupt enable 0: Error number interrupt disable 1: Error number interrupt enable
10	BOIE	Bus-off interrupt enable 0: Bus-off interrupt disable 1: Bus-off interrupt enable
9	PERRIE	Passive error interrupt enable 0: Passive error interrupt disable 1: Passive error interrupt enable
8	WERRIE	Warning error interrupt enable 0: Warning error interrupt disable 1: Warning error interrupt enable
7	Reserved	Must be kept at reset value
6	RFOIE1	Receive FIFO1 overfull interrupt enable 0: Receive FIFO1 overfull interrupt disable 1: Receive FIFO1 overfull interrupt enable
5	RFFIE1	Receive FIFO1 full interrupt enable 0: Receive FIFO1 full interrupt disable 1: Receive FIFO1 full interrupt enable
4	RFNEIE1	Receive FIFO1 not empty interrupt enable 0: Receive FIFO1 not empty interrupt disable 1: Receive FIFO1 not empty interrupt enable
3	RFOIE0	Receive FIFO0 overfull interrupt enable 0: Receive FIFO0 overfull interrupt disable 1: Receive FIFO0 overfull interrupt enable

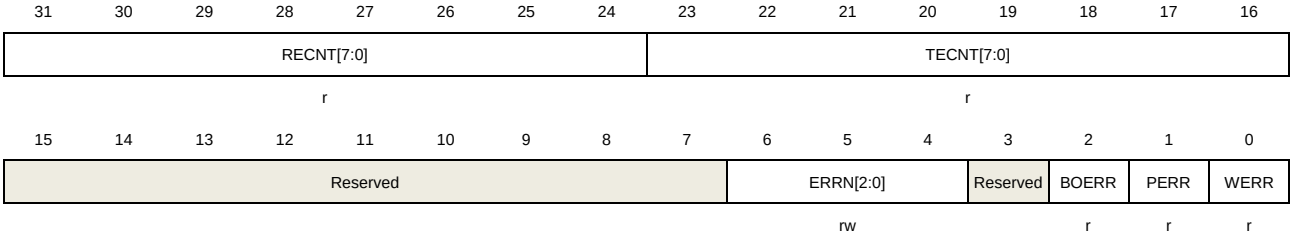
2	RFFIE0	Receive FIFO0 full interrupt enable 0: Receive FIFO0 full interrupt disable 1: Receive FIFO0 full interrupt enable
1	RFNEIE0	Receive FIFO0 not empty interrupt enable 0: Receive FIFO0 not empty interrupt disable 1: Receive FIFO0 not empty interrupt enable
0	TMEIE	Transmit mailbox empty interrupt enable 0: Transmit mailbox empty interrupt disable 1: Transmit mailbox empty interrupt enable

26.4.7. Error register (CAN_ERR)

Address offset: 0x18

Reset value: 0x0000 0000

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:24	RECNT[7:0]	Receive Error Count defined by the CAN standard
23:16	TECNT[7:0]	Transmit Error Count defined by the CAN standard
15:7	Reserved	Must be kept at reset value
6:4	ERRN[2:0]	Error number These bits indicate the error status of bit transformation. They are updated by the hardware. While the bit transformation is successful, they are equal to 0. Software can set these bits to 0b111. 000: No Error 001: Stuff Error 010: Form Error 011: Acknowledgment Error 100: Bit recessive Error 101: Bit dominant Error 110: CRC Error 111: Set by software

3	Reserved	Must be kept at reset value
2	BOERR	Bus-off error Whenever the CAN enters bus-off state, the bit will be set by the hardware. The bus-off state is entered on TECNT overflow, greater than 255.
1	PERR	Passive error Whenever the TECNT or RECNT is greater than 127, the bit will be set by the hardware.
0	WERR	Warning error Whenever the TECNT or RECNT is greater than or equal to 96, the bit will be set by the hardware.

26.4.8. Bit timing register (CAN_BT)

Address offset: 0x1C
Reset value: 0x0123 0000

This register has to be accessed by word(32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SCMOD	LCMOD	Reserved				SJW[1:0]		Reserved	BS2[2:0]			BS1[3:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						BAUDPSC[9:0]									
						rw									

Bits	Fields	Descriptions
31	SCMOD	Silent communication mode 0: Silent communication disable 1: Silent communication enable
30	LCMOD	Loopback communication mode 0: Loopback communication disable 1: Loopback communication enable
29:26	Reserved	Must be kept at reset value
25:24	SJW[1:0]	Resynchronization jump width Resynchronization jump width time quantum = SJW[1:0]+1
23	Reserved	Must be kept at reset value
22:20	BS2[2:0]	Bit segment 2 Bit segment 2 time quantum=BS2[2:0]+1
19:16	BS1[3:0]	Bit segment 1

		Bit segment 1 time quantum=BS1[3:0]+1
15:10	Reserved	Must be kept at reset value
9:0	BAUDPSC[9:0]	Baud rate prescaler The CAN baud rate prescaler

26.4.9. Transmit mailbox identifier register (CAN_TMIx) (x=0..2)

Address offset: 0x180, 0x190, 0x1A0

Reset value: 0xXXXX XXXX (bit0=0)

This register has to be accessed by word(32-bit)

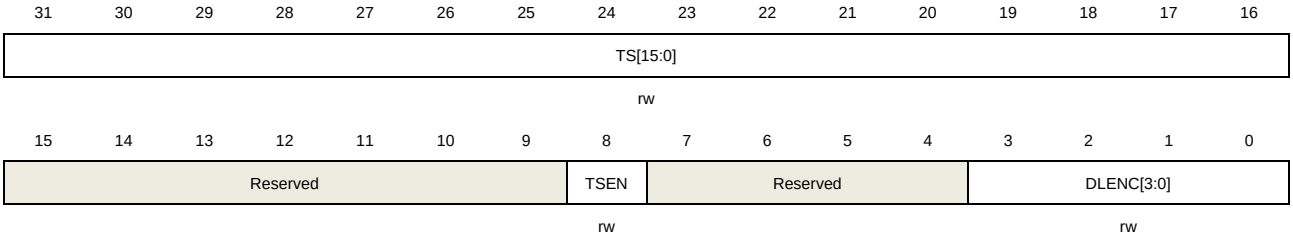
Bits	Fields	Descriptions
31:21	SFID[10:0]/EFID[28:18]	The frame identifier SFID[10:0]: Standard format frame identifier EFID[28:18]: Extended format frame identifier
20:16	EFID[17:13]	The frame identifier EFID[17:13]: Extended format frame identifier
15:3	EFID[12:0]	The frame identifier EFID[12:0]: Extended format frame identifier
2	FF	Frame format 0: Standard format frame 1: Extended format frame
1	FT	Frame type 0: Data frame 1: Remote frame
0	TEN	Transmit enable This bit is set by the software when one frame will be transmitted and reset by the hardware when the transmit mailbox is empty. 0: Transmit disable 1: Transmit enable

26.4.10. Transmit mailbox property register (CAN_TMPx) (x=0..2)

Address offset: 0x184, 0x194, 0x1A4

Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)



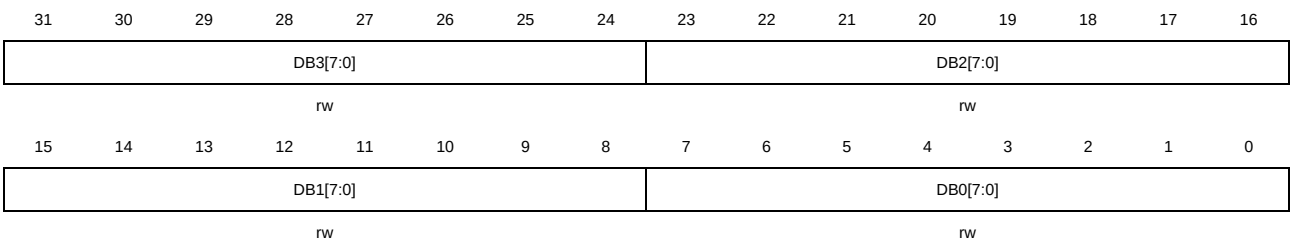
Bits	Fields	Descriptions
31:16	TS[15:0]	Time stamp The time stamp of frame in transmit mailbox.
15:9	Reserved	Must be kept at reset value
8	TSEN	Time stamp enable 0: Time stamp disable 1: Time stamp enable. The TS[15:0] will be transmitted in the DB6 and DB7 in DL This bit is available while the TTC bit in CAN_CTL is set.
7:4	Reserved	Must be kept at reset value
3:0	DLENC[3:0]	Data length code DLENC[3:0] is the number of bytes in a frame.

26.4.11. Transmit mailbox data0 register (CAN_TMDATA0x) (x=0..2)

Address offset: 0x188, 0x198, 0x1A8

Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)



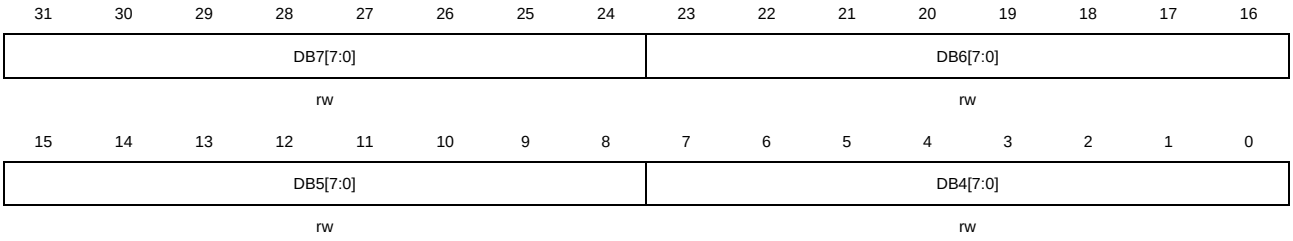
Bits	Fields	Descriptions

31:24	DB3[7:0]	Data byte 3
23:16	DB2[7:0]	Data byte 2
15:8	DB1[7:0]	Data byte 1
7:0	DB0[7:0]	Data byte 0

26.4.12. Transmit mailbox data1 register (CAN_TMDATA1x) (x=0..2)

Address offset: 0x18C, 0x19C, 0x1AC
Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)

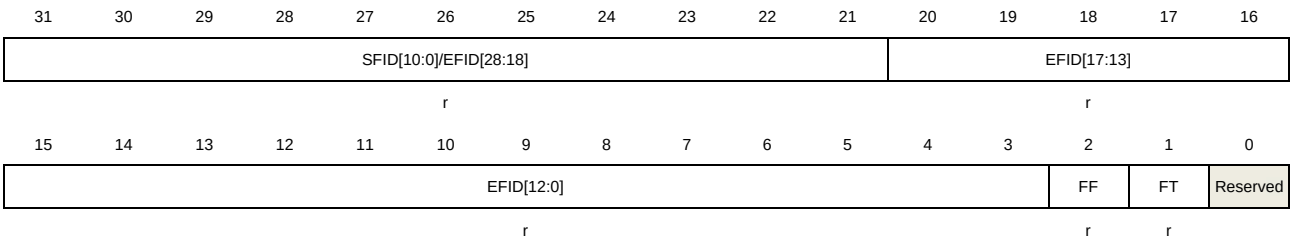


Bits	Fields	Descriptions
31:24	DB7[7:0]	Data byte 7
23:16	DB6[7:0]	Data byte 6
15:8	DB5[7:0]	Data byte 5
7:0	DB4[7:0]	Data byte 4

26.4.13. Receive FIFO mailbox identifier register (CAN_RFIFOMIx) (x=0,1)

Address offset: 0x1B0, 0x1C0
Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)



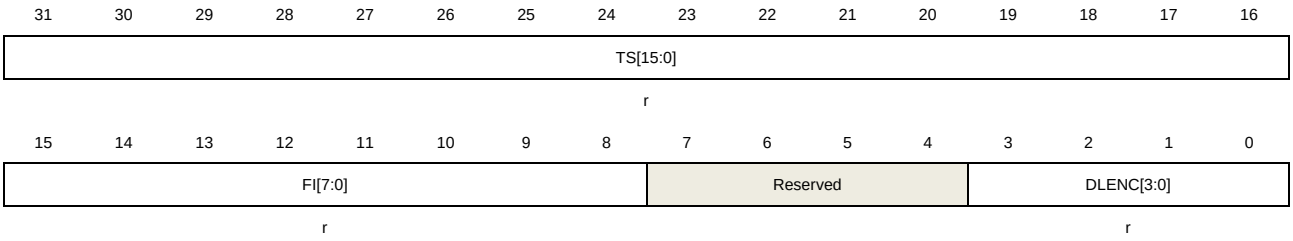
Bits	Fields	Descriptions
31:21	SFID[10:0]/EFID[28:18]	The frame identifier SFID[10:0]: Standard format frame identifier EFID[28:18]: Extended format frame identifier
20:16	EFID[17:13]	The frame identifier EFID[17:13]: Extended format frame identifier
15:3	EFID[12:0]	The frame identifier EFID[12:0]: Extended format frame identifier
2	FF	Frame format 0: Standard format frame 1: Extended format frame
1	FT	Frame type 0: Data frame 1: Remote frame
0	Reserved	Must be kept at reset value

26.4.14. Receive FIFO mailbox property register (CAN_RFIFOMPx) (x=0,1)

Address offset: 0x1B4, 0x1C4

Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)



Bits	Fields	Descriptions
31:16	TS[15:0]	Time stamp The time stamp of frame in transmit mailbox.
15:8	FI[7:0]	Filtering index The index of the filter by which the frame is passed.
7:4	Reserved	Must be kept at reset value
3:0	DLENC[3:0]	Data length code DLENC[3:0] is the number of bytes in a frame.

26.4.15. Receive FIFO mailbox data0 register (CAN_RFIFOMDATA0x) (x=0,1)

Address offset: 0x1B8, 0x1C8

Reset value: 0xXXXX XXXX

This register has to be accessed by word(32-bit)

27. Ethernet (ENET)

27.1. Overview

This chapter describes the Ethernet peripheral module. There is a media access controller (MAC) designed in Ethernet module to support 10/100Mbps interface speed. For more efficient data transfer between Ethernet and memory, a DMA controller is designed in this module. The support interface protocol for Ethernet is media independent interface (MII) and reduced media independent interface (RMII). This module is mainly compliant with the following two standards: IEEE 802.3-2002 and IEEE 1588-2002.

27.2. Characteristics

MAC feature

- 10Mbit/s and 100Mbit/s data transfer rates support.
- MII and RMII interface support
- Loopback mode support for diagnosis
- CSMA/CD Protocol for Half-duplex back-pressure operation support.
- IEEE 802.3x flow control protocol support. Automatic delay a pause time which is decoded from a receive pause frame after current transmitting frame complete. MAC automatically transmits pause frame or back pressure feature depending on fill level of RxFIFO in Full-duplex mode or in Half-duplex mode.
- Automatic transmission of pause frame on assertion and de-assertion of flow control input frame. Zero-quanta pause time length frame for Full-duplex operation. IEEE 802.3x flow control for Full-duplex operation support. Back pressure feature to the MAC core based on RxFIFO fill level (Cut-Through mode) support. IEEE 802.3x flow control for Half-duplex operation support.
- Software configurable for automatic PAD/CRC generation in transmits operation.
- Software configurable for automatic PAD/CRC stripping in receives operation.
- Software configurable for frame length to support standard frames with sizes up to 16 KB.
- Software configurable for inter-frame gap (40-96 bit times in steps of 8).
- Support different receiving filter mode.
- IEEE 802.1Q VLAN tag detection function support for reception frames.
- Support mandatory network statistics standard (RFC2819/RFC2665).

- Two types of wakeup frame detection: LAN remote wakeup frame and AMD Magic PacketTM frames.
- Support checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagram.
- Support Ethernet frame time stamping for both transmit and receive operation, which describes in IEEE 1588-2008, and 64 bit time stamps are given in each frame's status.
- Two independent FIFO of 2K Byte for transmitting and receiving.
- Support special condition frame discards handling, e.g. late collision, excessive collisions, excessive deferral or underrun.
- Calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum in frame transmit under Store-and-Forward mode.

DMA Feature

- Two types of descriptor addressing: Ring and Chain.
- Each descriptor can transfer up to 8 KB of data.
- Programmable normal and abnormal interrupt for many status conditions
- Round-robin or fixed-priority arbitration between reception and transmission controller.

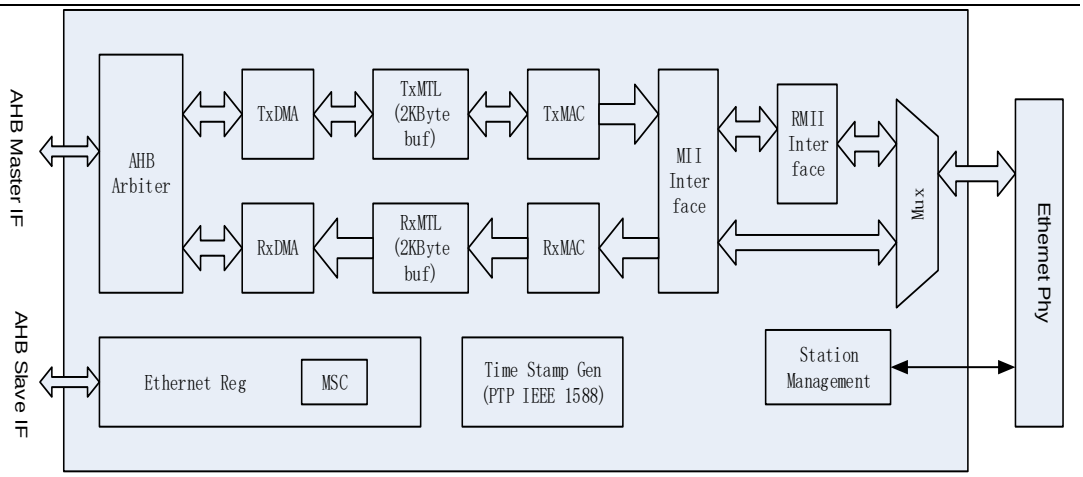
PTP Feature

- Support IEEE 1588 time synchronization function.
- Support two correction methods: Coarse or Fine.
- Pulse per second output.
- Preset target time reaching trigger and interrupt.

27.2.1. Block diagram

The Ethernet module is composed of a MAC module, MII/RMII module and a DMA module by descriptor control.

Figure 27-1. ENET module block diagram



The MAC module is connected to the external PHY by MII or RMII through one selection bit (refer to AFIO_PCF0 register). The SMI (Station Management Interface) is used to configure and manage external PHY.

Transmitting data module includes:

- TxDMA controller, used to read descriptors and data from memory and writes status to memory.
- TxMTL, used to control, management and store the transmit data. TxFIFO is implemented in this module and used to cache transmitting data from memory for MAC transmission.
- The MAC transmission relative control registers, used to control frame transmit.

Receiving data module includes:

- RxDMA controller, used to read descriptors from memory and writes received frame data and status to memory.
- RxMTL, used to control, management and store reception data. RxFIFO is implemented in this module and used to temporarily store received frame data before forwarding them into the system physical memory.
- The MAC reception relative control registers, used to control frame receive and marked the receiving state. Also a receiving filter with a variety of filtering mode is implemented in MAC, used to filter out specific Ethernet frame

Note: The AHB clock frequency must be at least 25 MHz when the Ethernet is used.

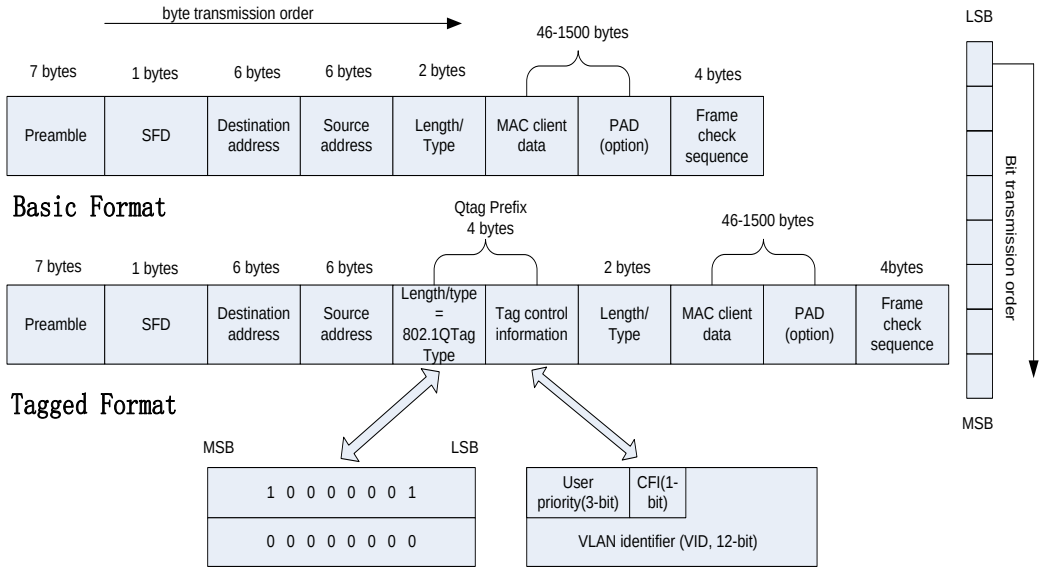
27.2.2. MAC 802.3 Ethernet packet description

Data communication of MAC can use two frame formats:

- Basic MAC frame format.
- Tagged MAC frame format (extension of the basic MAC frame format).

Figure 27-2 describes the structure of the frame (Basic and Tagged) that includes the following fields:

Figure 27-2. MAC/Tagged MAC frame format



Note: The Ethernet controller transmits each byte at LSB first except FCS field.

CRC calculation data comes from all bytes in the frame except the Preamble and SFD domain. The Ethernet frame's 32-bit CRC calculation value generating polynomial is fixed 0x04C11DB7 and this polynomial is used in all 32-bit CRC calculation places in Ethernet module, as follows:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

27.2.3. Ethernet signal description

Table below shows the MAC module that pin is used default and remapping functions and specific configuration in MII/RMII mode.

Table 27-1. Ethernet pin configuration

MAC signals	Pin	Pin configuration	MII default	MII remap	RMII default	RMII remap
ETH_MDC	PC1	AF output push-pull highspeed (50 MHz)	MDC		MDC

ETH_MII_RXD3	PD12	Floating input (reset state)		RXD3		

27.3. Function overview

27.3.1. Interface configuration

The Ethernet block can transmit and receive Ethernet packets from an off-chip Ethernet PHY connected through the MII/RMII interface. MII or RMII mode is selected by software and carry on the PHY management through the SMI interface.

SMI: Station management interface

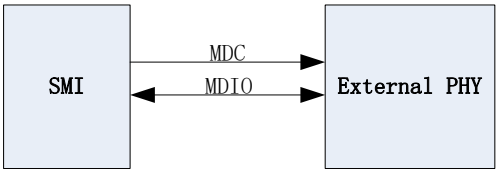
SMI is designed to access and configure PHY's configuration.

Station management interface (SMI) is performed through two wires to communicate with the external PHY: one clock line (MDC) and one data line (MDIO), it can access to the any PHY register. The interface supports accessing up to 32 PHYs, but only one register in one PHY can be addressed at the same time.

MDC and MDIO specific functions as follows:

- MDC: A clock of maximum frequency is 2.5 MHz. The pin remains low level when it is in idle state. The minimum high or low level lasts time of MDC must be 160ns, and the minimum period of MDC must be 400ns when it is in data transmission state.
- MDIO: Used to transfer data in conjunction with the MDC clock line, receiving data from external PHY or sending data to external PHY.

Figure 27-3. Station management interface signals



SMI write operation

Applications need to write transmission data to the ENET_MAC_PHY_DATA register and operate the ENET_MAC_PHY_CTL register as follows:

1) Set the PHY device address and PHY register address, and set PW to 1, so that can select write mode.

2) Set PB bit to start transmission. In the process of transaction PB is always high until the transfer is complete. Hardware will clear PB bit automatically.

The application can be aware of whether a transaction is complete or not through checking PB bit. When PB is 1, it means the application should not change the PHY address register contents and the PHY data register contents because of operation is running. Before writing PB bit to 1, application must poll the PB bit until it is 0.

SMI read operation

Applications need to operate the ENET_MAC_PHY_CTL register as follows:

1) Set the PHY device address and PHY register address and set PW to 0, so that can select read mode.

2) Set PB bit to start reception. In the process of reception PB is always high until the receiver is complete. Hardware will clear PB bit automatically.

The application can be aware of whether a transaction is complete or not through checking PB bit. When PB is 1, it means the application should not change the PHY address register contents and the PHY data register contents because of operation is running. Before writing PB bit to 1, application must poll the PB bit until it is 0.

Note: Because the PHY register address 16-31 register function is defined by each manufacturer, access different PHY device's this part should see according to the manufacturer's manual to adjust the parameters of applications. Details of catalog that firmware library currently supports the PHY device can refer to firmware library related instructions.

SMI clock selection

The SMI clock is generated by dividing application clock (AHB clock). In order to guarantee the MDC clock frequency is no more than 2.5MHz, application should set appropriate division factor according to the different AHB clock frequency. The following table lists the frequency factor corresponding AHB clock selection.

Table 27-2. Clock range

AHB clock	MDC clock	Selection
35~60MHz	AHB clock/26	0x3
20~35MHz	AHB clock/16	0x2
100~120 MHz	AHB clock/62	0x1
60~100MHz	AHB clock/42	0x0

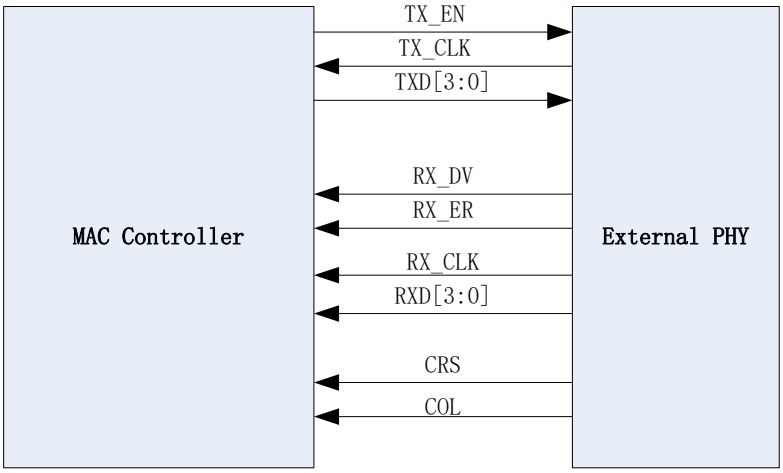
MII/RMII selection

The application can select the MII or RMII mode through the configuration bit 23 of the AFIO_PCF0 register ENET_PHY_SEL while the Ethernet controller is under reset state or before enabling the clocks. The MII mode is set by default.

MII: Media independent interface

The media-independent interface (MII) defines the interconnection between the MAC sub-layer and the PHY for data transfer at 10 Mbit/s or 100 Mbit/s.

Figure 27-4. Media independent interface signals



- **MII_TX_CLK**: clock signal for transmitting data. For the data transmission speed of 10Mbit/s, the clock is 2.5MHz, for the data transmission speed of 100Mbit/s, the clock is 25MHz.

- **MII_RX_CLK**: Clock signal for receiving data. For the data transmission speed of 10Mbit/s, the clock is 2.5MHz, for the data transmission speed of 100Mbit/s, the clock is 25MHz.

- **MII_TX_EN**: Transmission enable signal. It must be asserted synchronously with the first bit of the preamble and must remain asserted while all bits to be transmitted are presented to the MII.

- **MII_TXD[3:0]**: Transmit data line, each 4 bit data transfer, data is valid when the MII_TX_EN signal is effective. MII_TXD[0] is the least significant bit and MII_TXD[3] is the most significant bit. While MII_TX_EN is de-asserted the transmit data must have no effect upon the PHY.

- **MII_CRS**: Carrier sense signal, only working in Half-duplex mode and controlled by the PHY. It is active when either transmit or receive medium is in non idle state. The PHY must ensure that the MII_CRS signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the TX and RX clock.

- **MII_COL**: Collision detection signal, only working in Half-duplex mode, controlled by the PHY. It is active when a collision on the medium is detected and must it will remain active while the collision condition continues. This signal is not required to transition synchronously with respect to the TX and RX clock.

- **MII_RXD[3:0]**: Receive data line, each 4 bit data transfer; data are valid when the MII_RX_DV signal is effective. MII_RXD[0] is the least significant bit and MII_RXD[3] is the most significant bit. While MII_RX_DV is de-asserted and MII_RX_ER is asserted, a specific MII_RXD[3:0] value is used to indicate specific information (see Table 27-3).

- **MII_RX_DV**: Receive data valid signal, controlled by the PHY. It is asserted when PHY is presenting data on the MII for reception. It must be asserted synchronously with the first 4-bit of the frame and must remain asserted while all bits to be transmitted are presented on the MII. It must be de-asserted prior to the first clock cycle that follows the final 4-bit. In order to receive the frame correctly, the effective signal starting no later than the SFD field.

- **MII_RX_ER**: Receive error signal. It must be asserted for one or more RX clock to indicate MAC detected an error in the receiving process. The specific error reason needs to cooperate with the state of the MII_RX_DV and the MII_RXD[3:0] data value (see Table 27-3).

Table 27-3. Rx interface signal encoding

MII_RX_ER	MII_RX_DV	MII_RXD[3:0]	Description
0	0	0000 to 1111	Normal inter-frame
0	1	0000 to 1111	Normal reception frame data
1	0	0000	Normal inter-frame
1	0	0001 to 1101	Reserved
1	0	1110	False carrier indication
1	0	1111	Reserved
1	1	0000 to 1111	Data reception with errors

MII clock sources

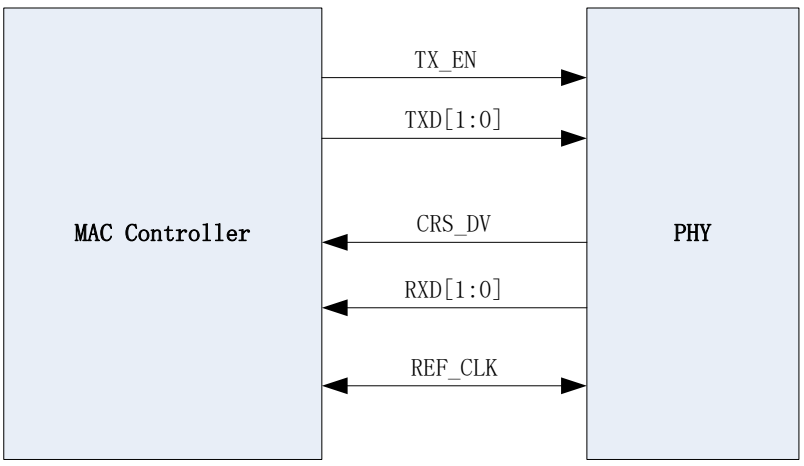
To generate both TX_CLK and RX_CLK clock signals, the external PHY needs an external 25MHz clock. This 25MHz clock does not require the same one with MAC clock. It can use the external 25MHz crystal or the output clock of microcontroller's CK_OUT0 pin. If the clock source is selected from CK_OUT0 pin, the MCU needs to configure the appropriate PLL to ensure the output frequency of CK_OUT0 pin is 25MHz.

RMII: Reduced media independent interface

The reduced media-independent interface (RMII) specification reduces the pin count during Ethernet communication. According to the IEEE 802.3 standard, an MII contains 16 pins for data and control. The RMII specification is dedicated to reduce the pin count to 7.

The RMII block has the following characteristics:
- The clock signal needs to be increased to 50MHz and only one clock signal.
- MAC and external PHY use the same clock source
- Using the 2-bit wide data transceiver

Figure 27-5. Reduced media-independent interface signals



MII/RMII bit transmission order

No matter which interface (MII or RMII) is selected, the bit order of transmit/receive is LSB first.

The deference between MII and RMII is bit number and sending times. MII is low 4bits first and then high 4bits, but RMII is the lowest 2bits, low 2bits, high 2bits and the highest 2bits.

For example: a byte value is: 10011101b (left to right order: high to low)
Transmission order for MII use 2 cycles: 1101 -> 1001 (left to right order: high to low)
Transmission order for RMII use 4 cycles: 01 -> 11 -> 01 -> 10 (left to right order: high to low)

RMII clock sources

To ensure the synchronization of the clock source, the same clock source is selected for the MAC and external PHY which is called REF_CLK. The REF_CLK input clock can be connected to the external 50MHz crystal or microcontroller CK_OUT0 pin. If the clock source is from CK_OUT0 pin, then the MCU needs to configure the appropriate PLL to ensure the output frequency of CK_OUT0 pin is 50MHz.

27.3.2. MAC function overview

MAC module can achieve the following functions:

Data package (transmission and reception)

- Frame detecting/decoding and frame boundary delimitation.
- Addressing (handling source address and destination address).
- Error conditions detect.

Medium access management in Half-duplex mode

- Medium allocation (prevent conflicts).
- Conflict resolution (dealing with conflicts).

The MAC module can work in two modes

- Half-duplex mode: with the CSMA/CD algorithm to contend for using of the physical medium, at the same time only one transmission direction is active between two stations is active.
- Full-duplex mode: simultaneous transmission and reception without any conflict mode, if all of the following conditions are satisfied: 1) PHY supports the feature of transmission and reception operations at the same time. 2) Only two devices connect to the LAN and the two devices are both configured for Full-duplex mode.

Transmission process of MAC

All transactions are controlled by the dedicated DMA controller and MAC in Ethernet. After received the sending instruction, the TxDMA fetches the transmit frames from system memory and pushes them into the TxFIFO, then the data in TxFIFO are poped to MAC for sending on MII/RMII interface. The method of popping is according to the selected TxFIFO mode (Cut-Through mode or Store-and-Forward mode, the specific definition see the next paragraph).For convenient, application can configure automatically hardware calculated CRC and insert it to the FCS domain of Ethernet frame function. The entire transmission process complete when the MAC received the frame termination signal from transmit FIFO. When transmission completed, the transmission status information will be composed of MAC and write return to the DMA controller, the application can query through the DMA current transmit descriptor.

Operation for popping data from FIFO to the MAC has two modes:

- In Cut-Through mode, as soon as the number of bytes in the FIFO crosses or equals the configured threshold level or when the end-of-frame flag in descriptor is written, the data is ready to be popped out and forwarded to the MAC. The threshold level is configured using the TTHC bits of ENET_DMA_CTL.
- In Store-and-Forward mode, only after an integrated frame is stored in the FIFO, the frame is popped towards the MAC. But there is another condition for FIFO popping out data but the frame is not integrated. This is when the transmit FIFO size is smaller than the Ethernet frame to be transmitted, the frame is popped towards the MAC when the transmit FIFO becomes almost full.

Handle special cases

In the transmission process, due to the insufficient TxDMA descriptor or misuse of FTF bit in ENET_DMA_CTL register (when this bit is set, it will clear FIFO data and reset the FIFO pointer, after clear operation is completed, it will be reset), there will be a transmit data underflow fault occurs because of insufficient data in FIFO. At the same time MAC will identify such data underflow state and write relevant status flag.

If one transmit frame uses two TxDMA descriptors for sending data, then the first segment (FSG) and the last segment (LSG) of the first descriptor should be 10b and the second ones should be 01b.If both the FSG bit of the first and the second descriptor are set and the LSG bit in the first descriptor is reset, then the FSB bit of the second descriptor will be ignored and these two descriptors are considered to sending the only one frame.

If the byte length of one transmission MAC frame’s data field is less than 46 (for Tagged MAC frame is less than 42), application can configure the MAC for automatically adding a load of content of ‘0’ bit to make the byte length of frame’s data field in accordance with the relevant domain of definition of IEEE802.3 specification. At the same time, if automatically adding zeros function is performed, the MAC will certainly calculate CRC value of the frame and append it to the frame’s FCS field domain no matter what configuration of DCRC bit in the

descriptor is.

Transmission management of MAC

Jabber timer

In case of one station occupies the PHY for a long time, there is a jabber timer designed for cutting off the frame whose length is more than 2048 bytes. By default, jabber timer is enabled so when application is transmitting a frames whose byte length is more then 2048, the MAC will only transmit 2048 bytes and drop the last ones.

Collision condition solve mechanism – Re-transmission

When the MAC is running under Half-duplex mode, collision may happen when MAC is transmitting frame data on interface. When no more than 96 bytes data popped from FIFO towards MAC and collision condition occurs, the re-transmission function is active. In this case, MAC will stop current transmitting and then read frame data from FIFO again and send them on interface again. When more than 96 bytes data popped from FIFO towards MAC and collision condition occurs, MAC will abort transmitting current frame data and not re-transmit it. Also MAC will set late collision flag in descriptor to inform application.

Transmit status word

Transmit status word includes many transmit state flags for application and are updated after the complete the transmission of the frame. If timestamp function is enable, the timestamp value is also write back to transmit descriptor along with transmit status.

Transmit FIFO flush operation

Application can clear TxFIFO and reset the FIFO data pointer by setting FTF bit (bit 20) of ENET_DMA_CTL register. The flush operation will be executed at once no matter whether TxFIFO is popping data to MAC. This results in an underflow event in the MAC transmitter, and the makes frame transmission abort. At the same time, MAC returns state information of frame and transmit status words transferred to the application. The status of such a frame is marked with both underflow and frame flush events (TDES0 bits 1 and 13). When the transmit data in TxFIFO is flushed, the transmit status word will be written back to descriptor. After the status is written, the flush operation is complete. When a flush operation is received, all the following data which should be popped from TxFIFO into MAC will be dropped unless a new FSG bit of descriptor is received. After operation completed, the FTF bit of ENET_DMA_CTL register is then automatically cleared.

Transmit flow control

The MAC manages transmission frame through back pressure (in Half-duplex mode) and the pause control frame (in Full-duplex mode) for flow control.

- Half-duplex mode flow control : Back Pressure

When MAC is configured in Half-duplex mode, there are two conditions to trigger the back pressure feature. Both of the two conditions are triggered to enable back pressure function which is implemented by sending a special pattern (called jam pattern) 0x5555 5555 once to notify conflict to all other sites. The first condition is triggered by application setting the FLCB/BKPA bit in ENET_MAC_FCTL register. The second condition occurs during receiving frame. When MAC receiver is receiving frame, the byte number of RxFIFO is more and more great. When this number is greater than the high threshold (RFA bits in ENET_MAC_FCTH), MAC will set the back pressure pending flag. If this flag is set and a new frame presents on interface, MAC will send a jam pattern to delay receiving this new frame a back pressure time. After this back pressure time is end, external PHY will send this new frame again. If the number of the RxFIFO is not less than low threshold (RFD bits in ENET_MAC_FCTH) during this back pressure time, a jam pattern is send again. If the number of the RxFIFO is less than low threshold (RFD bits in ENET_MAC_FCTH) during this back pressure time, MAC resets the back pressure pending flag and is enable to receive the new frame instead of sending jam pattern.

- Full-duplex mode flow control : Pause Frame

The MAC uses a mechanism named "pause frame" for flow control in Full-duplex mode. Receiver can send a command to the sender for informing it to suspend transmission a period of time. If the application sets transmit flow control bit TFCEN in ENET_MAC_FCTL register, MAC will generate and transmit a pause frame when either of two conditions is satisfied in Full-duplex mode. There are two conditions to start transmit pause frames:

1) Application sets FLCB/BKPA bit in ENET_MAC_FCTL register to immediately send a pause frame. When doing this, MAC sends a pause frame right now with the pause time value PTM configured in ENET_MAC_FCTL register. If application considers the pause time is no need any more because the transmit frame can be transmitted without pause time, it can end the pause time by setting the pause time value PTM bits in ENET_MAC_FCTL register to 0 and set FLCB/BKPA bit to send this zero pause time frame.

2) MAC automatically sends pause time when the RxFIFO is in some condition. When MAC is receiving frame, RxFIFO will be fill in many receive data. At same time RxFIFO pops out data to RxDMA for forwarding to memory. If the popping frequency is lower than MAC pushing frequency, the number of bytes in RxFIFO is getting great. Once the data amount in RxFIFO is greater than the active threshold value (RFA bits in ENET_MAC_FCTH) of flow control, MAC will send a pause frame with PTM value in it. After sending pause frame, MAC will start a counter with configured reload value PLTS in ENET_MAC_FCTL register, when configured PLTS time has spent, the MAC will check RxFIFO again. If the byte number in RxFIFO is also greater than active threshold value, the MAC sends a pause time again. When the byte number of RxFIFO is lower than the de-active threshold value, MAC maybe send a pause frame with zero time value in frame’s pause time field if DZQP bit in ENET_MAC_FCTL register is reset. This zero-pause time frame can inform send station that RxFIFO is almost empty and can receive new data again.

Transmit inter-frame gap management

MAC can manage the interval time between two frames. This interval time is called frame gap time. For Full-duplex mode, after complete sending a frame or MAC entered idle state, the gap time counter starts counting. If another transmit frame presents before this counter has not reach the configured IGBS bit time in ENET_MAC_CFG register, this transmit frame will be pended unless the counter reach the gap time. But if the second transmit frame presents after the gap time counter has reached the configured gap time, this frame will send immediately. For Half-duplex mode, the gap time counter follows the Truncated Binary Exponential Backoff algorithm. Briefly speaking, the gap time counter starts after the previous frame has completed transmitting on interface or the MAC entered idle state, and there are three conditions may occur during the gap time:

1) The carrier sense signal active in the first 2/3 gap period. In this case, the counter will reload and restart.
2) The carrier sense signal active in the last 1/3 gap period. In this case, the counter will not reload but continue counting, and when reaches gap time, the MAC sends the second frame
3) The carrier sense signal not active during the whole gap period. In this case, the counter stops after reaches the configured gap time and sends frame if the second frame has pended.

Transmit checksum offload

The MAC supports transmit checksum offload. This feature can calculate checksum and insert it in the transmit frame, and detect error in the receive frame. This section describes the operation of the transmit checksum offload.

Note: This function is enabled only when the TSFD bit in the ENET_DMA_CTL register is set (TxFIFO is configured to Store-and-Forward mode) and application must ensure the TxFIFO deep enough to store the whole transmit frame. If the depth of the TxFIFO is less than the frame length, the MAC only does calculation and insertion for IPv4 header checksum field.

See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460 and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6 and ICMPv6 packet header specifications, respectively.

- IP header checksum

If the value is 0x0800 in type field of Ethernet frame and the value is 0x4 in the IP datagram's version field, checksum offload module marks the frame as IPv4 package and calculated value replace the checksum field in frame. Because of IPv6 frame header does not contain checksum field, the module will not change any value of the IPv6's header field. After IP header checksum calculation end, the result is stored in IPHE bit (bit 16 in TDES0). The following shows the conditions under which the IPHE bit can be set:

1) For IPv4 frame type:
   A). type field is 0x0800 but version filed in IP header is not 0x4.
   B). IPv4 header length field value is greater than total frame byte length

C). the value of IPv4 header length field is less than 0x5 (20 bytes)

2) For IPv6 frame type:

A). type field is 0x86dd but version field in IP header is not 0x6

B). the frame ends before the IPv6 standard header or extension header (as given in the corresponding header length field in an extension header) has been completely received.

- TCP/UDP/ICMP payload checksum

The checksum offload module processes the IPv4 or IPv6 header (including extension headers) and marks the type of frame (TCP, UDP or ICMP).

But when the following frame cases are detected, the checksum offload function will be bypassed and these frames will not be processed by the checksum offload module:

1) Incomplete IPv4 or IPv6 frames

2) IP frames with security features (e.g. authentication header, security payload)

3) IP frames without TCP/UDP/ICMPv4/ICMPv6 payload

4) IPv6 frames with routing headers

The checksum offload module calculates the TCP, UDP, or ICMP payload and inserts the result into its corresponding field in the header. It has two modes when working, as follows:

1) TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's checksum field. The checksum field is included in the checksum calculation, and then replaced by the final calculated checksum.

2) Checksum offload module clears the contents of the checksum field in the transmission frame and make calculation which includes TCP, UDP, or ICMPv6 pseudo-header data and will instead the transmission frame's original checksum field by the final calculation results.

After calculated by checksum offload module, the result can be found in IPPE bit (bit 12 in TDES0). The following shows the conditions under which the IPPE bit can be set:

1) In Store-and-Forward mode, frame has been forwarded to MAC transmitter but no EOF is written to TxFIFO

2) Frame is ended but the byte numbers which the payload length field of the frame indicates has not been reached

If the packet length is greater than the marked length, checksum module does not report errors, the excess data will be discarded as padding bytes. If the first condition of IPPE error is detected, the value of the checksum does not insert a TCP, UDP or ICMP header. If the second condition of IPPE error is detected, checksum calculation results will still insert the appropriate header fields.

Note: For ICMP packets over IPv4 frame, the checksum field in the ICMP packet must always be 0x0000 in both modes due to such packets are not defined pseudo-headers.

MAC receive filters

The MAC filter is divided into error filtering (such as too short frame, CRC error and other bad frame filtering) and address filtering. This section mainly describes the address filtering.

Address filtering

Address filtering use the static physical address (MAC address) filter and hash list filter for implementing the function. If the FAR bit in the ENET_MAC_FRMF register is '0' (by default), only the frame passed the filter will be received. This function is configured according to the parameters of the application (frame filter register) to filter the destination or/and source address of unicast or multicast frame (The difference between an individual address and a group address is determined by I/G bit in the destination address field) and report the result of the corresponding address filtering. The frame not pass through the filter will be discarded.

Note: If the FAR bit in the ENET_MAC_FRMF register is set to 1, frames are all thought passed the filter. In this case, even the filter result will also be updated in receive descriptor but the result will not affect whether current frame passes the filter or not.

Unicast frame destination address filter

For a unicast frame, application has two modes for filtering: the one is using static physical address (by setting HUF bit to ‘0’), the other is using hash list (by setting HUF bit to ‘1’).

- Static physical address (SPA) filtering

In the filter mode, MAC supports using four MAC addresses for unicast frame filtering. In this way, the MAC compares all 6 bytes of the received unicast address to the programmed MAC address. MAC address 0 is always used and MAC address 1 to address 3 can be configured to use or not. Each byte of MAC address 1 to MAC address 3 register can be masked for comparison with the corresponding destination address byte of received frame by setting the corresponding mask byte bits (MB) in the corresponding register.

- Hash list filtering

In this filter mode, MAC uses a HASH mechanism. MAC uses a 64-bit hash list to filter the received unicast frame. This filter mode obeys the followings two filtering steps:

1) The MAC calculates the CRC value of the received frame’s destination address

2) Using the high 6 bits of the calculated CRC value as the index to retrieve the hash list. If the corresponding value of hash list is 1, the received frame passes through the filter, conversely, fail the filter.

The advantage of this type of filter is that it can cover any possible address just using a small table. But the disadvantage is that the filter is imperfect and sometimes the frames should be dropped are also be received by mistake.

Multicast frame destination address filter

Application can enable the multicast frame MAC address filtering by cleaning the MFD bit in register ENET_MAC_FRMF. By configuring the value of HMF bit in ENET_MAC_FRMF register application can choose two ways just like unicast destination address filtering for address filtering.

Hash or perfect address filter

The destination address (DA) filter can be configured to pass a frame when its DA matches either the hash list filter or the static physical address filter by setting the HPFLT bit in the ENET_MAC_FRMF register and setting the corresponding HUF or HMF bit in the ENET_MAC_FRMF register.

Broadcast frame destination address filter

At default, the MAC unconditionally receives the broadcast frames. But when setting BFRMD bit in register ENET_MAC_FRMF, MAC discards all received broadcast frames.

Unicast frame source address filter

Enable MAC address 1 to MAC address 3 register and set the corresponding SAF bit in the MAC address high register, the MAC compares and filter the source address (SA) field in the received frame with the values programmed in the SA registers. MAC also supports the group filter on the source address. If the SAFLT bit in frame filter register ENET_MAC_FRMF is set, MAC drops the frame that failed the source address filtering; meanwhile the filter result will reflect by SAFF bit in RDES0 of DMA receive descriptor. When the SAFLT bit is set, the destination address filter is also at work, so the result of the filter is simultaneous determined by DA and SA filter. This means that, as long as a frame does not pass any one of the filters (DA filter or SA filter), it will be discarded. Only a frame passing the entire filter can be forwarded to the application.

Reverse filtering operation

MAC can reverse filter-match result at the final output whether the destination address filtering or source address filtering. By setting the DAIFLT and SAIFLT bits in ENET_MAC_FRMF register, this address filter reverse function can be enabled. DAIFLT bit is used for unicast and multicast frames' DA filtering result, SAIFLT bit is used for unicast and multicast frames SA filtering result.

The following two tables summarize the destination address and source address filters working condition at different configuration.

Table 27-4. Destination address filtering table

Frame Type	PM	HPFLT	HUF	DAIFLT	HMF	MFD	BFRMD	DA filter operation
Broadcast	1	-	-	-	-	-	-	Pass

Frame Type	PM	HPFLT	HUF	DAIFLT	HMF	MFD	BFRMD	DA filter operation
	0	-	-	-	-	-	0	Pass
	0	-	-	-	-	-	1	Fail
Unicast	1	-	-	-	-	-	-	Pass all frames
	0	-	0	0	-	-	-	Pass on perfect/group filter match
	0	-	0	1	-	-	-	Fail on perfect/group filter match
	0	0	1	0	-	-	-	Pass on hash filter match
	0	0	1	1	-	-	-	Fail on hash filter match
	0	1	1	0	-	-	-	Pass on hash or perfect/group filter match
	0	1	1	1	-	-	-	Fail on hash or perfect/group filter match
Multicast	1	-	-	-	-	-	-	Pass all frames
	-	-	-	-	-	1	-	Pass all frames
	0	-	-	0	0	0	-	Pass on perfect/group filter match and drop PAUSE control frames if PCFRM = 0x
	0	0	-	0	1	0	-	Pass on hash filter match and drop PAUSE control frames if PCFRM = 0x
	0	1	-	0	1	0	-	Pass on hash or perfect/group filter match and drop PAUSE control frames if PCFRM = 0x
	0	-	-	1	0	0	-	Fail on perfect/group filter match and drop PAUSE control frames if PCFRM = 0x
	0	0	-	1	1	0	-	Fail on hash filter match and drop PAUSE control frames if PCFRM = 0x
	0	1	-	1	1	0	-	Fail on hash or perfect/group filter match and drop PAUSE control frames if PCFRM = 0x

Table 27-5. Source address filtering table

Frame type	PM	SAIFLT	SAFLT	SA filter operation
Unicast	1	-	-	Pass all frames
	0	0	0	Pass status on perfect/group filter match but do not drop frames that fail
	0	1	0	Fail status on perfect/group filter match but do not drop frame
	0	0	1	Pass on perfect/group filter match and drop frames that fail
	0	1	1	Fail on perfect/group filter match and drop frames that fail

Promiscuous mode

If the PM bit in ENET_MAC_FRMF register is set, promiscuous mode is enable. Then the address filter function is bypassed, all frames are thought passed through the filter. At the same time the receive status information DA / SA error bit is always '0'.

Pause control frame filter

When MAC received pause frame, it will detect 6 bytes DA field in the frame. If UPFDT bit in ENET_MAC_FCTL register is 0, it is determined by whether the value of the DA field conforms to the unique value (0x0180C2000001) with IEEE-802.3 specification control frames. If UPFDT bit in ENET_MAC_FCTL register is set, MAC additionally compares DA field with the programmed MAC address for bit match. If DA field match and receive flow control is enabled (RFCEN bit in ENET_MAC_FCTL register is set), the corresponding pause control frame function will be triggered. Whether this filter passed pause frame is forwarded to memory is depending on the PCFRM[1:0] bit in ENET_MAC_FRMF register.

Reception process of MAC

Received frames will be pushed to the RxFIFO. The MAC strips the preamble and SFD of the frame, and starts pushing the frame data beginning with the first byte following the SFD to the RxFIFO. If IEEE 1588 time stamp function is enabled, the MAC will record the current system time when a frame's SFD is detected. If the frame passes the address filter, this time stamp is passed on to the application by writing it to descriptor.

The MAC can automatically strip PAD and FCS field data when the length/type field of received frame is less than 1536 if APCD bit is set. MAC pushes the data of the frame into RxFIFO up to the count specified in the length/type field, then starts dropping bytes (including the FCS field). If the value of Length/Type field is greater than or equal to 0x600, regardless of whether the option of automatic CRC and pad stripping function is enabled, the MAC pushes all received frame data to Rx FIFO.

If the watchdog timer is enabled (WDD bit in ENET_MAC_CFG is reset), a frame has more than 2048 bytes (DA + SA + LT + DATA + FCS) will be cut off receiving when has received 2048 bytes. If the watchdog timer is disabled, the MAC can extend the max receiving data bytes to 16384(16K Bytes), any data beyond this number will be cut off.

When RxFIFO works at Cut-Through mode, it starts popping out data from RxFIFO when the number of FIFO is greater than threshold value (RTHC bits in ENET_DMA_CTL register). After all data of a frame pop out, receive status word is sent to DMA for writing back to descriptor. In this mode, if a frame has started to forward to application by DMA from FIFO, the forwarding will continue until the frame is end even if frame error is detected. Although the error frame is not discarded, the error status will reflect in descriptor status field.

When RxFIFO works at Store-and-Forward mode (set by RSFD bit in ENET_DMA_CTL), DMA reads frame data from RxFIFO only after RxFIFO has completed received the whole frame. In this mode, if the MAC is configured to discard all error frames, then only valid frames

without any error can be read out from RxFIFO and forward to the application. Once the MAC detects an SFD signal on the interface, a receive operation is started. The MAC strips the preamble and SFD before processing the frame. The header fields are checked by filtering and the FCS field used to verify the CRC for the frame. The frame is discarded by MAC if it fails to pass the address filter.

Reception management of MAC

Receive operation on multi-frame handling

It is different from transmit operation, after receiving the last byte of a frame, the MAC can judge the status of the receiving operation, so the second received frame's forwarding is surely followed by the first received frame data and status.

Receive flow control

In Full-duplex mode, the MAC can detect the pause control frames, and perform it by suspending a certain time which is indicated in pause time field of detected pause control frame and then to transmit data. This function can set by RFCEN bit in ENET_MAC_FCTL register. If this function is not enabled, the MAC will ignore the received pause frames. If this function is enabled, MAC can decode this frame. Type field, opcode field and pause time field in the frame are all recognized by the MAC. During the pause time period, if MAC received a new pause frame, the new pause time filed value is loaded to the pause time counter immediately. If the new pause time filed is zero, then the pause time counter stops and transmit operation recovers. Application can configure PCFRM bit in ENET_MAC_FRMF register to decide the solving method for such control frame.

Receive checksum offload

Receive checksum offload is enabled when IPFCO bit in ENET_MAC_CFG register is set. Receive checksum offload can calculate the IPv4 header checksum and check whether it matches the contents of the IPv4 header checksum field. The MAC identifies IPv4 or IPv6 frames by checking for the value of 0x0800 or 0x86DD respectively in the received Ethernet frame type field. This method is also used to identify frames with VLAN tags. Header checksum error bits in DMA receive descriptor (the 7 bit in RDES0) reflects the header checksum result. This bit is set if received IP header has the following errors:

- Any mismatch between the IPv4 calculation result by checksum offload module and the value in received frame's checksum field.
- Any inconsistent between the data type of Ethernet type field and IP header version field.
- Received frame length is less than the length indicated in IPv4 header length field, or IPv4 or IPv6 header is less than 20 bytes.

Receive checksum offload also identifies the data type of the IP packet is TCP, UDP or ICMP, and calculate their checksum according to TCP, UDP or ICMP specification. Calculation process can include data of TCP/UDP/ICMPv6 pseudo-header. Payload checksum error bits

in DMA receive descriptor (bit 0 in RDES0) reflects the payload checksum result. This bit is set if received IP payload has the following errors:

- Any mismatch between the TCP, UDP or ICMP checksum calculation result by checksum offload and the received TCP/UDP/ICMP frame's checksum field.
- Any inconsistent between the received TCP, UDP or ICMP data length and length of IP header.

The received checksum offload does not calculate the following conditions: Incomplete IP packets, IP packets with security features, packets of IPv6 routing header and data type is not TCP, UDP or ICMP.

Error handling

- If RxFIFO becomes full but the last received byte is not the end of frame (EOF), the RxFIFO will discard the whole frame data and return an overflow status. Also the counter of counting the overflow condition times will plus 1.
- If the RxFIFO is configured in Store-and-Forward mode, the MAC can filter and discard all error frames. But according to the configuration of FERF and FUF bit in ENET_DMA_CTL register, RxFIFO can also receive and forward such error frame and the frame that length is less than the minimum length.
- If the RxFIFO is configured in Cut-Through mode, not all the error frames can be dropped. Only when the start of frame (SOF) has not been read from RxFIFO and the receive frame has been detected error status, the RxFIFO will discard the whole error frame.

Receive status word

After receiving a complete frame, the MAC will analysis and record some state information about the frame and receiving process. These detail status information will write back to the receive descriptor and DMA status flag. Application can check these flags for upper protocol implementation.

Note: The value of frame length is 0 means that for some reason (such as FIFO overflow or dynamically modify the filter value in the receiving process, resulting did not pass the filter, etc), frame data is not written to FIFO completely.

MAC loopback mode

Often, loopback mode is used for testing and debugging hardware and software system for application. The MAC loopback mode is enabled by setting the LBM bit in ENET_MAC_CFG register. In this mode, the MAC transmitter sends the Ethernet frame to its own receiver. This mode is disabled by default.

27.3.3. MAC statistics counters: MSC

For knowing the statistics situation of transmitting and receiving frames, there is a group of

counters designed for gathering statistics data. These MAC counters are called statistics counters (MSC).In Section ‘Register Description’, there is a detailed description of the function of these registers.

When the transmit frame does not appear the following situation, it can be called ‘fine frame’ and MSC transmit counters will automatically update:

- Frame underflow
- No carrier
- Lose of carrier
- Excessive deferral
- Late collision
- Excessive collision
- Jabber Timeout

When the receiving frame does not appear the following situation, it can be called ‘fine frame’ and MSC reception counters will automatically update:

- Alignment error
- CRC mismatch(calculated CRC value is different from FSC field value)
- Runt frame (frame length is shorter than 64 bytes)
- Length error (length field value is different from the actual received data bytes)
- Range error (length field value is larger than maximum size of defined in IEEE802.3,which is 1518 for untagged frame and 1522 for VLAN tagged frame)
- Error signal valid on pin MII_RX_ER

Note: Only when the discarded frame is a short frame whose length is less than 6 bytes (no complete receives the DA), MSC reception counter is updated.

27.3.4. Wake up management: WUM

Ethernet (ENET) module supports two wakeup methods from Deep-sleep mode. The one is remote wakeup frame and the other is Magic Packet wakeup frame. For reduce power consuming, the host system and Ethernet can be powered down and thus the circuit driven by HCLK or transmit clock is stop working. But the circuit driven by receive clock will continues working for listening wakeup frame. If application sets the PWD bit in ENET_MAC_WUM register, the Ethernet enters into power-down state. In power-down state, MAC ignores all the frame data on the interface until the power-down state is exited. For exiting power-down state, application can choose one or both of the two methods mentioned above. Setting WFEN bit in ENET_MAC_WUM register can make Ethernet wakeup if a remote wakeup frame received and setting MPE bit in ENET_MAC_WUM register can make Ethernet wakeup if a Magic

Packet frame is received. When any type of wakeup frame is present on interface and corresponding wakeup function is enabled, Ethernet will generate a wakeup interrupt and exit power-down state at once.

Remote wakeup frame detection

Setting WFEN bit in ENET_MAC_WUM register can enable remote wakeup detection. When the MAC is in power-down state and remote wakeup function enable bit is set, MAC wakeup frame filter is active. If the received frame passes the address filter and filter CRC-16 matches the incoming examined pattern, then MAC identified the received wakeup frame, and then MAC returns to normal working state. Even if the length of the wakeup frame exceeds 512 bytes, as long as the frame has a correct CRC value, it is still considered to be effective. After received the remote wakeup frame, the WUFR bit in ENET_MAC_WUM register will be set. If remote wakeup interrupt is not masked, then a WUM interrupt is generated.

Remote wakeup frame filter register

Wakeup frame filter register is made up of eight different registers but shared the same register offset address. So the inner pointer points the next filter register when the filter register address is accessed by writing or reading. Whatever operation, write or read, it is strongly recommended to operate eight times sequentially. This means continuously write 8 times will configure the filter registers and continuously read 8 times will get the values of filter registers.

Figure 27-6. Wakeup frame filter register

Wakeup Frame Filter Register 0	Filter 0 Byte Mask							
Wakeup Frame Filter Register 1	Filter 1 Byte Mask							
Wakeup Frame Filter Register 2	Filter 2 Byte Mask							
Wakeup Frame Filter Register 3	Filter 3 Byte Mask							
Wakeup Frame Filter Register 4	Reserve	Filter 3 Command	Reserve	Filter 2 Command	Reserve	Filter 1 Command	Reserve	Filter 0 Command
Wakeup Frame Filter Register 5	Filter 3 Offset		Filter 2 Offset		Filter 1 Offset		Filter 0 Offset	
Wakeup Frame Filter Register 6	Filter 1 CRC - 16				Filter 0 CRC - 16			
Wakeup Frame Filter Register 7	Filter 3 CRC - 16				Filter 2 CRC - 16			

- Filter n Byte mask

This register field defines using which bytes of the frame to determine the received frame is wakeup frame or not by filter n (n=0, 1, 2, 3). Bit 31 must be set to 0. Bit 30 to bit 0 are valid byte mask. If bit m(m means byte number) is set, the filter n offset + m of the receiving frame is calculated by the CRC unit, conversely, filter n offset + m is ignored.

- Filter n command

This four bits command controls the operation of the filter n. The bit 3 of the field is address type selection bit. If this bit is 1, the detection only detects a multicast frame and if this bit is 0, the detection only detects a unicast frame. Bit 2 and bit 1 must be set to 0. Bit 0 is the filter switch bit. Setting it to 1 means enable and 0 means disable.

- Filter n offset

It is used in conjunction with filter n byte mask field. This register specifies offset (within the frame) of the first byte which the filter n uses to check. The minimum allowable value is 12, it represents the byte 13 in the frame (offset value 0 indicates the first byte of the frame).

- Filter n CRC-16

This register field contains the filter comparing CRC-16 code which is used for comparing the calculated CRC-16 from frame data.

Magic packet detection

Another wakeup method is detecting Magic Packet frame (see 'Magic Packet Technology', Advanced Micro Devices). A Magic Packet frame is a special frame with formed packet solely intended for wakeup purposes. This packet can be received, analyzed and recognized by the Ethernet block and used to trigger a wakeup event. Setting MPE bit in ENET_MAC_WUM register can enable this function. This type of frame's format is as follows: starts by 6 continuous bytes of the value 0xFF (0xFFFF FFFF FFFF) in anywhere of the frame behind the destination and source address field, then there are 16 duplicate MAC addresses without any interruption and pause. If there is any discontinuity between repeating it 16 times, MAC needs to re-detect 0xFFFF FFFF FFFF in the receive frame. WUM module continuously monitors each frame received. When a Magic Packet frame passing the address filter, MAC will detect its format with Magic Packet format, once the format is matched the WUM will make MAC wakeup from power down state. Then the MAC wakes up from power-down state after receiving a Magic Packet frame. Module also accepts multicast frames as Magic Packet frame.

Example: An example of a Magic Packet with station address 0xAABB CCDD EEFF is the following (MISC indicates miscellaneous additional data bytes in the packet):

<DESTINATION><SOURCE><MISC>

……FF FF FF FF FF FF

AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF

AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF

AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF

AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF AABB CCDD EEFF

<MISC><FCS>

Upon detecting a Magic Packet, the MPKR bit in ENET_MAC_WUM register will be set. If the Magic Packet interrupt is enabled, the corresponding interrupt will generate.

Precautions during system power-down state

When the MCU is in Deep-sleep mode, if external interrupt line 19 is enabled, Ethernet WUM module can still detecting frames. Because the MAC in power-down state needs detecting Magic Packet or remote wakeup frame, the REN bit in ENET_MAC_CFG register must be maintained set. The transmit function should be turned disable during the power-down state by clearing the TEN bit in the ENET_MAC_CFG register. Moreover, the Ethernet DMA block should be disabled during the power-down state, because it is not necessary that the Magic Packet or remote wakeup frame is forwarded to the application. Application can disable the Ethernet DMA block by clearing the STE bit and the SRE bit (for the TxDMA and the RxDMA, respectively) in the ENET_DMA_CTL register.

Follow steps are recommended for application to enter and exit power-down state:

1. Wait the current sending frame completes and then reset the TxDMA block by clearing STE bit in ENET_DMA_CTL register.

2. Clear the TEN and REN bit in ENET_MAC_CFG register to disable the MAC's transmit and receive function.

3. Check the RS bit in ENET_DMA_STAT register, waiting receive DMA read out all the frames in the receive FIFO and then close RxDMA.

4. Configure and enable the external interrupt line 19, so that it can generate an interrupt or event. If EXTI line 19 is configured to generate an interrupt, application still needs to modify ENET_WKUP_IRQ interrupt handling procedures to clear the pending bit of the EXTI line 19.

5. Set the MPEN or WFEN (or both) bit in ENET_MAC_WUM register to enable Magic Packet or Remote Wakeup frame(or both) detection.

6. Setting PWD bit in ENET_MAC_WUM register to enter power-down state.

7. Setting REN bit in ENET_MAC_CFG register to make MAC's receive function work.

8. Make MCU enter Deep-sleep mode.

9. After received a wakeup type frame, the Ethernet module exits the power-down state.

10. Reading the ENET_MAC_WUM register to clear the power management event flags. Enable MAC's transmit function and enable TxDMA and RxDMA.

11. Initialize the MCU system clock: enable HXTAL and configure the RCU unit.

27.3.5. Precision time protocol: PTP

The majority of protocols are implemented by the UDP layer application software. The PTP module of the MAC is mainly to recording the transmitting and receiving PTP packets' precision time and returning it to application.

Specific details about the precise time protocol (PTP) please see the document "IEEE

Standard 1588™".

Reference clock source

System reference time in Ethernet is maintained by a 64-bit register whose high 32-bit indicates 'second' time and low 32-bit indicates 'subsecond', this is defined in IEEE 1588 specification.

The input PTP reference clock is used to drive the system reference time (also called system time for short) and capture timestamp value for PTP frame. The frequency of this reference clock must be configured no less than the resolution of timestamp counter. The synchronization accuracy between the master node and slave node is around 0.1us.

Synchronization accuracy

The accuracy of time synchronization depends on the following factors:

1) PTP reference clock input period
2) Characteristics of the oscillator (drift)
3) Frequency of the synchronization procedure.

System time correction method

The 64-bit PTP system time update by the PTP input reference clock. The PTP system time is used as the source to record transmission/reception frame's timestamp. The system time initialization and calibration support two methods: coarse method and fine method. The purpose of calibration is to correct the frequency offset.

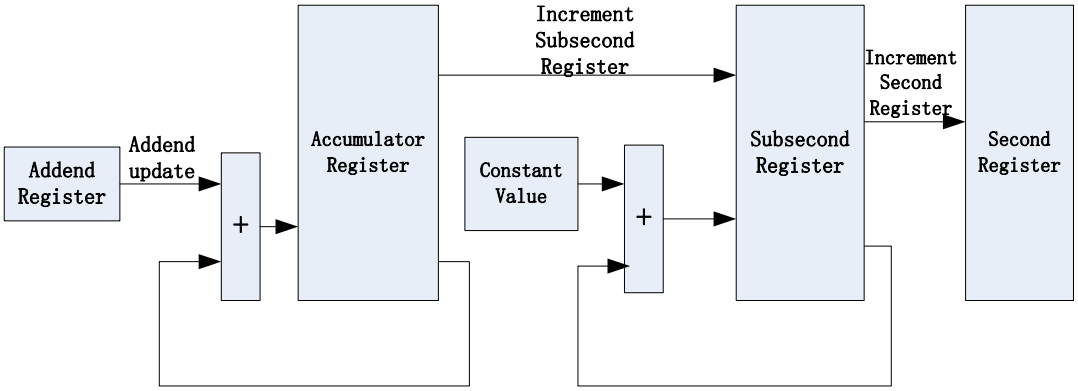
If the coarse correction method is selected, application can configure PTP timestamp update register (ENET_PTP_TSUH and ENET_PTP_TSUL) for system time initialization or correction. If TMSSTI bit is set, PTP timestamp update register is used for initialization and if TMSSTU bit is set, PTP timestamp update register is used for adjust system time by adding or subtracting.

If fine correction method is selected, operation is different. The fine correction method corrects system time not in a single clock cycle. The fine correction frequency can be configured by application to make slave clock frequency smoothly adapt master clock without unpredictability large jitter.

This method is referred to the value of ENET_PTP_TSADDEND added to the accumulator in each HCLK cycle. PTP module will produce a pulse to increase the value of ENET_PTP_TSL register when the accumulator overflowed. The increased value when this pulse occurs is in ENET_PTP_SSINC register.

The following illustration shows the fine correction algorithm process:

Figure 27-7. System time update using the fine correction method



The following concrete example is used to descript the fine correction method how to update the system time:

Assuming the accuracy of the system time update circuit required to achieve 20ns, which means the frequency of update is 50MHz. If the reference clock of HCLK is 75MHz, the frequency ratio is calculated as 75/50, result is 1.5. Hence, the addend (TMSA bit in ENET_PTP_TSADDEND register) value to be set is 2^{32}/1.5, which is equal to 0xAAAA AAAA. If the reference clock frequency drifts lower, for example, down to 65MHz, the frequency ratio changes to 65/50=1.3, the value to be set in the addend register is 2^{32}/1.30 = 0xC4EC 4EC4. If the reference clock drift higher, for example, up to 85MHz, the value addend register must be 0xA000 0000. Initially, the slave clock frequency is set to Clock Addend Value (0) in the addend register. This value is calculated as above. In addition to configuring the addend counter, application also needs to set subsecond increment register to ensure to achieve the precision of 20ns. The value of the register is to update values of timestamp low 32-bit register after accumulator register overflow. Because the timestamp low register (bit 0 to 30) represents the subsecond value of system time, the precision is 10^9ns/2^{31}=0.46ns. So in order to make the system time accuracy to 20ns, sub second increment register value should be set to 20/0.46 = 0d43.

Note: The algorithm described below based on constant delay transferred between master and slave devices (Master-to-Slave-Delay). Synchronous frequency ratio will be confirmed by the algorithm after a few Sync cycles.

Algorithm is as follows:

- Define the master sends a SYNC message to slave time: MSYNCT (n).
  Define the slave local time SLOCALT (n).
  Define the master local time MLOCALT (n).
  Calculation: MLOCALT (n) = MSYNCT (n) + Master-to-Slave-Delay (n)
- Define the master clock count number between two SYNC message sent: MCLOCKC(n)
  Calculation: MCLOCKC (n) = MLOCALT (n) – MLOCALT (n-1)
  Define the slave clock count number between two received SYNC messages: SCLOCKC (n)

Calculation: SCLOCKC (n) = SLOCALT (n) - SLOCALT (n-1)

- Define the difference between these two count numbers: DIFFCC (n)
  Calculation: DIFFCC (n) = MCLOCKC (n) - SCLOCKC (n)
- Define the slave clock frequency-adjusting factor: SCFAF (n)
  Calculation: SCFAF (n) = (MCLOCKC (n) + DIFFCC (n)) / SCLOCKC (n)
- Define the Clock Addend Value for addend register: Clock Addend Value (n)
  Clock Addend Value (n) = SCFAF (n) * Clock Addend Value (n-1)

Note: During the actual operation, application may need more than once SYNC message between master and slave to lock.

System time initialization procedure

Setting TMSEN bit in ENET_PTP_TSCTL register to 1, timestamp function is enabled. Each time after this bit is set from reset, application must initialize the timestamp counter at first. Initialization steps as follow:

1. Setting bit 9 in the ENET_MAC_INTMSK register to mask the timestamp trigger interrupt
2. Setting bit 0 in the ENET_PTP_TSCTL register to enable timestamp function
3. Configure the subsecond increment register according to the PTP clock frequency precision
4. If application hopes to use fine correction method, configure the timestamp addend register and set bit 5 in the ENET_PTP_TSCTL register to 1. If application hopes to use coarse correction method, please jump directly to step 7 and step 4-6 can be ignored.
5. Poll the bit 5 in the ENET_PTP_TSCTL register until it is cleared
6. Set bit 1 in the ENET_PTP_TSCTL register to 1 to choose fine correction method
7. Configure the timestamp update high and low register with the value of system time application wants to initialize
8. Send initialization command by setting bit 2 in the ENET_PTP_TSCTL register
9. The timestamp counter starts counting as soon as the initialization process complete

System time update steps under coarse correction method

1. Program the offset (may be negative) value in the timestamp update high and low registers
2. Set bit 3 (TMSSTU) in the ENET_PTP_TSCTL register to update the timestamp register
3. Poll TMSSTU bit until it is cleared.

System time update steps under fine correction method

1. Calculate the value of the desired system clock rate corresponding to the addend register (calculation formula has explained before)
2. Program the addend register, and set the bits 5 in ENET_PTP_TSCTL register
3. Program the target high and low register and reset the bit 9 of the ENET_MAC_INTMSK register to allow time stamp interrupt
4. Set bit 4 (TMSITEN) in ENET_PTP_TSCTL register
5. When an interrupt is generated by this event, read out the value of ENET_MAC_INTF register and clear the corresponding interrupt flag
6. Rewrite the old value of addend register to timestamp addend register and set bit 5 in ENET_PTP_TSCTL register

Transmission and reception of frames with the PTP feature

After enabled the IEEE 1588 (PTP) timestamp function, timestamp is recorded when the frame's SFD field is outputting from the MAC or the MAC receives a frame's SFD field. Each transmitted frame can be marked in TxDMA descriptor to indicate whether a timestamp should be captured or not.

Together with the state information of frame, the recorded timestamp value will also be stored in the corresponding transmission/reception descriptor. The 64-bit timestamp information of transmission frame is written back to the transmit descriptor and the 64-bit timestamp information of reception frame is written back to the receive descriptor. See the detailed description in "Transmit DMA descriptor" and "Receive DMA descriptor".

PTP trigger internal connection with TIMER1

MAC can provide trigger interrupt when the system time is no less than the target time. Using an interrupt imports a known latency and an uncertainty in the command execution time. In order to calculate the time of this known latency part, when the system time is greater than target time, the PTP module sets an output signal. Set bit 29 of AFIO_PCF0 register to 0 can make this signal internally connected to the ITI0 input of TIMER1. For this feature designed, no uncertainty is introduced because the clock of the TIMER1 and PTP reference clock (HCLK) are synchronous.

PTP pulse-per-second (PPS) output signal

Application configures ETH_PPS_OUT pin to AF output push-pull to enable the PPS output function. This function can output a signal with the pulse width of 125ms which can be used to check the synchronization between all nodes in the network. To test the difference between the slave clock and the master clock, both of the slave and master can output PPS and connect them to one oscilloscope for clock measurement.

27.3.6. DMA controller description

Ethernet DMA controller is designed for frame transmission between FIFO and system memory which can reduce the occupation of CPU. Communication between the CPU and the DMA is achieved by the following two kinds of data structures:

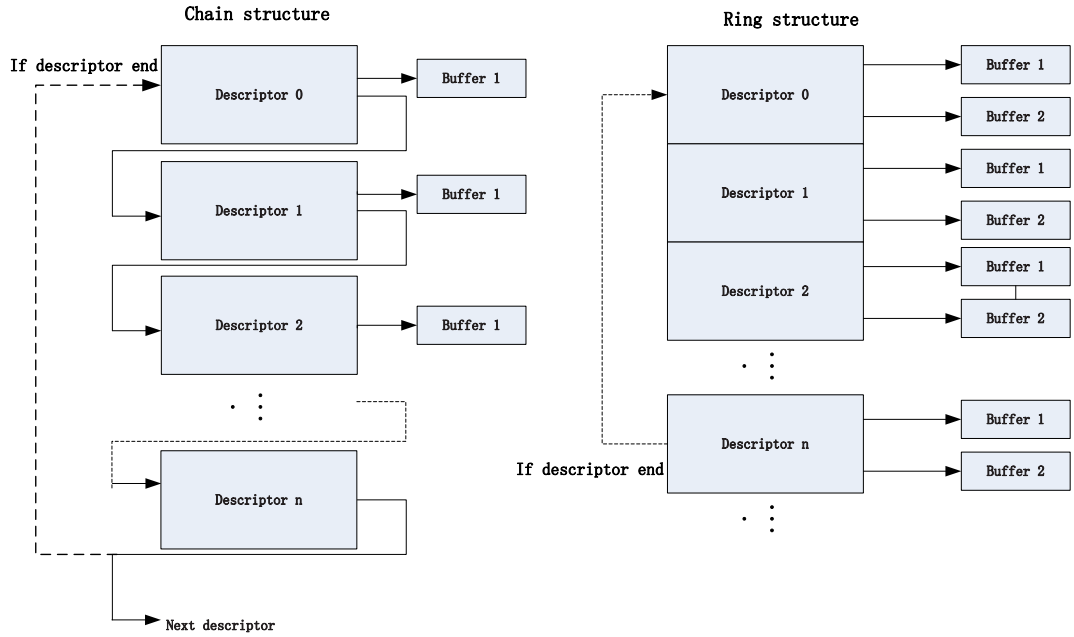
- Descriptor table (ring or chain type) and data buffer
- Control and status register

Applications need to provide the memory for storage of descriptor tables and data buffers. Descriptors that reside in the memory act as pointers to these buffers. Transmission has transmission descriptor and reception has reception descriptor. The base address of each table is stored in ENET_DMA_TDTADDR and ENET_DMA_RDTADDR register. Descriptors of transmission constituted by 4 descriptor word (TDES0-TDES3). Likewise, reception descriptors constituted by 4 descriptor word (RDES0-RDES3). Each descriptor can point to a maximum of two buffers. The value of the buffer 2 can be programmed to the second data address or the next descriptor address which is determined by the configured descriptor table type: Ring or Chain. Buffer space only contains frame data which are located in host's physical memory space. One buffer can store only one frame data but one frame data can be stored in more than one buffer which means one buffer can only store a part of a frame. When chain structure is set, descriptor table is an explicitly one and when ring structure is set, descriptor table is an implicitly one. Explicit chaining of descriptors is accomplished by configuring the second address chained in both receive and transmit descriptors (RDES1[14] and TDES0[20]), at this time RDES2 and TDES2 are stored the data buffer address, RDES3 and TDES3 should be stored the next descriptor address, this connection method of descriptor table is called chain structure. Implicitly chaining of descriptors is accomplished by clearing the RDES1[14] and TDES0 [20], at this time RDES2, TDES2 and RDES3, TDES3 should be all stored the data buffer address, this connection method of descriptor table is called ring structure. When current descriptor's buffer address is used, descriptor pointer will point to the next descriptor. If chain structure is selected, the pointer points to the value of buffer 2. If ring structure is selected, the pointer points to an address calculated as below:

Next descriptor address = Current descriptor address + 16 + DPSL*4

If current descriptor is the last one in descriptor table, application needs to set the bit 21 in TDES0 or bit 15 in RDES1 to inform DMA the current descriptor is the last one of the table in ring structure. At this time, the next descriptor pointer points back to the first descriptor address of the descriptor table. In chain structure, can also set TDES3 or RDES3 value to point back to the first descriptor address of the descriptor table. The DMA skips to the next frame buffer when the end of frame is detected.

Figure 27-8. Descriptor ring and chain structure



Alignment rule for data buffer address

The DMA controller supports all alignment types: byte alignment, half-word alignment and word alignment. This means application can configure the buffer address to any address. But during the operation of the DMA controller, access address is always word align and is different between write and read access. Follow example describes the detail:

Buffer Reading: Assuming the transmit buffer address is 0x2000 0AB2, and 15 bytes need to be transferred. After starting operating, the DMA controller will read five word addresses which are 0x2000 0AB0, 0x2000 0AB4, 0x2000 0AB8, 0x2000 0ABC and 0x2000 0AC0. But when sending data to the FIFO, the first two bytes (0x2000 0AB0 and 0x2000 0AB1) and the last 3 bytes (0x2000 0AC1, 0x2000 0AC2 and 0x2000 0AC3) will be dropped.

Buffer Writing: Assuming the receive buffer address is 0x2000 0CD2, and 16 bytes need to be stored. After starting operating, the DMA controller will write five times 32-bit data from address 0x2000 0CD0 to 0x2000 0CE0. But the first 2 bytes (0x2000 0CD0 and 0x2000 0CD1) and the last 2 bytes (0x2000 0CE2 and 0x2000 0CE3) will be substituted by the virtual bytes.

Note: DMA controller will not write any data out of the defined buffer range.

The effective length of the buffer

For the frame transmitting process, the effective length of the buffer is the same as the value configured by application in TDES1. As mentioned before, a transmitting frame can use one or more descriptors to indicate the frame information which means a frame data can be located in many buffers. When the DMA controller reads a descriptor which the FSG bit in TDES0 is set, it knows the current buffer is pointing to a new frame and the first byte of the frame is included. When the DMA controller reads a descriptor with FSG bit and LSG bit in TDES0 are both reset, it knows the current buffer is pointing to a part of current frame. When

the DMA controller reads a descriptor with LSG bit in TDES0 is set, it know the current buffers is pointing to the last part of the current frame. Normally one frame is stored only in one buffer (because buffer size is large enough for a normal frame), so FSG bit and LSG bit are set in the same descriptor.

For the frame receiving process, the receive buffer size must be word align. But for word-align buffer address or not word-align buffer address, the operation is different from transmitting. When the receive buffer address is word align, it's no difference with transmitting process, the effective length of the buffer is the same as the value configured by application in RDES1. When the receive buffer address is not word align, the effective length of the buffer is less than the value configured by application in RDES1. The effective length of the buffer should be the size value minus the low two bits value of buffer address. For example, assuming the total buffer size is 2048 bytes and buffer address is 0x2000 0001, the low two bits are 0b01, the effective length of the buffer is 2047 bytes whose address range is from 0x20000001 (for the first received frame byte) to 0x2000 07FF.

When a start of frame (SOF) is received, the FSG bit is set by DMA controller and when the end of the frame (EOF) is received, the LSG bit is set. If the receive buffer size is programmed to be large enough to store the whole frame, the FSG and the LSG bit are set in the same descriptor. The actual frame length FRML can be read from RDES0. So application can calculate the left unused buffer space. The RxDMA always uses a new descriptor to receive the start of next frame.

Arbitration for TxDMA and RxDMA controller

There are two types of arbitration method designed for improving the efficiency of DMA controller between transmission and reception: fixed-priority and round-robin. When DAB bit in ENET_DMA_BCTL register is reset, arbiter selects round-robin method. The arbiter allocates the data bus in the ratio set by the RTPR bits in ENET_DMA_BCTL, when both of TxDMA and RxDMA controller request access simultaneously. When DAB bit in ENET_DMA_BCTL register is set, arbiter selects fixed-priority, and the RxDMA controller always has higher priority over the TxDMA.

Error response to DMA controller

During the operation of the DMA controller, when a response error presents on the bus, the DMA controller considers a fatal error occurs and stops operating at once with error flags written to the DMA status register (ENET_DMA_STAT). After such fatal error (response error) occurs, application must reset the Ethernet module and reinitialize the DMA controller.

DMA controller initialization for transmission and reception

Before using the DMA controller, the initialization must be done as follow steps:

1. Set the bus access parameters by writing the ENET_DMA_BCTL register
2. Mask unnecessary interrupt source by configuring the ENET_DMA_INTEN register

3. Program the Tx and Rx descriptor table start address by writing the ENET_DMA_TDTADDR register and the ENET_DMA_RDTADDR register
4. Configure filter option by writing related registers
5. According to the auto-negotiation result with external PHY, set the SPD bit and DPM bit for selecting the communication mode (Half-duplex/Full-duplex) and the communication speed (10Mbit/s or 100Mbit/s). Set the TEN and REN bit in ENET_MAC_CFG register to enable MAC transmit and receive operations.
6. Set STE bit and SRE bit in ENET_DMA_CTL register to enable TxDMA controller and RxDMA controller

Note: If the HCLK frequency is too much low, application can enable RxDMA before set REN bit in ENET_MAC_CFG register to avoid RxFIFO overflow at start time.

TxDMA configuration

Operate on second frame in buffer

When OSF bit in ENET_DMA_CTL is reset, the order of the transmitting is follows: the first is reading transmit descriptor, followed by reading data from memory and writing to FIFO, then sending frame data on interface through MAC and last wait frame data transmitting complete and writing back transmitting status.

Above procedure is TxDMA's standard transmitting procedure but when HCLK is much faster than TX_CLK, the efficiency of transmitting two frames will be greatly reduced.

To avoid the case mentioned above, application can set OSF to 1.If so, the second frame data can be read from the memory and push into FIFO without waiting the first frame's status writing back. OSF function is only performed between two neighboring frames.

TxDMA operation mode (A) (default mode): Non-OSF

The TxDMA controller in Non-OSF mode proceeds as follows:

1. Initialize the frame data into the buffer space and configure the descriptor (TDES0-3) with DAV bit of TDES0 sets to 1
2. Enable TxDMA controller by setting STE bit in ENET_DMA_CTL register
3. The TxDMA controller starts continue polling and performing transmit descriptor. When the DAV bit in TDES0[31] that TxDMA controller read is cleared, or any error condition occurs, the controller will enter suspend state and at the same time both the transmit buffer unavailable bit in ENET_DMA_STAT and normal interrupt summary bit in ENET_DMA_STAT register are set. If entered into suspend state, operation proceeds to Step 8
4. When the DAV bit in TDES0[31] of the acquired descriptor is set, the DMA decodes the transmit frame configured and the data buffer address from the acquired descriptor

5. DMA retrieve data from the memory and push it into the TxFIFO of MAC
6. The TxDMA controller continues polling the descriptor table until the EOF data (LSG bit is set) is transferred. If the LSG bit of current descriptor is reset, it will be closed by resetting the DAV bit after all buffer data pushed into TxFIFO. Then the TxDMA controller waits to write back descriptor status and IEEE 1588 timestamp value if enabled
7. After the whole frame is transferred, the transmit status bit (TS bit in ENET_DMA_STAT register) is set only when INTC bit in TDES0[30] is set. Also an interrupt generates if the corresponding interrupt enable flag is set. The TxDMA controller returns to Step 3 for the next frame
8. In the suspend state, application can make TxDMA returns to running state by writing any data to ENET_DMA_TPEN register and clearing the transmit underflow flag. Then the TxDMA controller process turns to Step 3.

TxDMA operation mode (B): OSF

The TxDMA controller supports transmitting two frames without waiting status write back of the first frame, this mode is called operation on second frame (OSF). When the frequency of system is much faster than the frequency of the MAC interface (10Mbit/s or 100Mbit/s), the OSF mode can improve the sending efficiency. Setting OSF bit in ENET_DMA_CTL register can enable this mode. When the TxDMA controller received EOF of the first frame, it will not enter the state of waiting status write back but to fetch the next descriptor, if the DAV bit and FSG bit of the next descriptor is set, the TxDMA controller immediately read the second frame data an push them into the MAC FIFO.

The TxDMA controller in OSF mode proceeds as follows:

1. Follow steps 1-6 operation in TxDMA default mode
2. The TxDMA controller retrieves the next descriptor without closing the previous frame's last descriptor in which the LSG bit is set
3. If the DAV bit of the next descriptor is set, the TxDMA controller starts reading the next frame's data from the buffer address. If the DAV bit of the next descriptor is reset, TxDMA controller enters suspend state and the next operation goes to Step 7.
4. TxDMA controller continues polling descriptor and frame data until the EOF is transferred. If a frame is described with more than one descriptor, the intermediate descriptors are all closed by TxDMA controller after fetched.
5. The TxDMA controller enters the state of waiting for the transmission status and time stamp of the previous frame (if timestamp enabled). With writing back status to descriptor, the DAV bit is also cleared by TxDMA controller
6. After the whole frame is transferred, the transmit status bit (TS bit in ENET_DMA_STAT register) is set only when INTC bit in TDES0[30] is set. Also an interrupt generates if the corresponding interrupt enable flag is set. The TxDMA controller returns to Step 3 for

the next frame if no underflow error occurred in previous frame. If underflow error of the previous frame is occurred, the TxDMA controller enters in suspend state and the next operation goes to Step 7.

7. In suspend state, when the status information and timestamp value (if the function is enable) of the transmitting frame is available, the TxDMA controller writes them back to descriptor and then close it by setting DAV=0 of descriptor.

8. In suspend state, application can make TxDMA returns to running state by writing any data to ENET_DMA_TPEN register and clearing the transmit underflow flag. Then the TxDMA controller process goes to Step 1 or Step 2.

Transmit frame format in buffer

According to IEEE 802.3 specification described before, a frame structure is made up of such fields: Preamble, SFD, DA, SA, QTAG (option), LT, DATA, PAD (option), and FCS.

The Preamble and SFD are automatically generated by the MAC, so the application only need store the DA, SA, QTAG(if needed), LT, DATA, DATA, PAD(if needed), FCS(if needed) parts. If the frame needs padding which means PAD and FCS parts are not stored in buffer, then application can configure the MAC to generate the PAD and FCS. If the frame only need FCS which means only FCS part is not stored in buffer, the application can configure the MAC to generate FCS. The DPAD bit and DCRC bit are designed to achieve the generate function of the PAD and FCS field.

Transmit frame processing

As mentioned before, a frame can span over several buffers which means several descriptors. When the FSG bit is set, the descriptor indicates the start of the frame and when the LSG bit is set, the descriptor indicates the end of the frame. All the buffers among these descriptors store the whole frame data. When the last descriptor is fetched and buffer finished reading, the transmitting status will write back to it. The other descriptors (here means the descriptor whose LSG bit is reset) of the current frame will not be changed by TxDMA controller except the DAV bit will be reset to 0. After starting transfer frame data from memory to FIFO, the transmitting has not actually start. The real start time for sending frame on interface is depended on TxDMA mode: Cut-Through mode or Store-and-Forward mode. The former mode starts sending when the byte number of FIFO is greater than configured threshold and the latter mode starts sending when the whole frame data are transferred into FIFO or when the FIFO is almost full.

Suspend during transmit polling

The DMA controller keeps querying the transmit descriptor after the transmission is started. If either of the following conditions happens, the DMA controller will enter suspend state and the transmit polling will stop. Though the DMA entered suspend state, the descriptor pointer is maintained to the descriptor following of the last closed descriptor.

- The DMA controller fetches a descriptor with DAV=0, then it enters suspend state and stops polling. In this case, the NI bit and TBU bit in ENET_DMA_STAT register are set.
- The MAC FIFO is empty during sending a frame on interface which means an error of underflow occurs. In this case, the AI bit and TU bit in ENET_DMA_STAT register are set. Also the transmit error status will write back to transmit descriptor.

Transmit DMA descriptor with IEEE 1588 timestamp format

When TTSEN bit is set, the timestamp function is enabled. The TxDMA controller writes transmit timestamp status TTMSS and timestamp back to descriptor TDES2 and TDES3 after the frame transmission complete.

TxDMA descriptors

The TxDMA descriptor structure consists of four 32-bit words: TDES0 ~ TDES3. The descriptions of TDES0, TDES1, TDES2 and TDES3 are given below:

Note: When a frame is described by more than one descriptor, only the control bits of the first descriptor are accept by TxDMA controller (except INTC). But the status and timestamp (if enabled) are written back to the last descriptor.

Figure 27-9. Transmit descriptor

Bits	Fields	Descriptions
31	DAV	DAV bit The DMA clears this bit either when it completes the frame transmission or the buffer allocated in the descriptor is read completely. This bit of the frame's first descriptor

		must be set after all subsequent descriptors belonging to the same frame have been set. 0: The descriptor is available for CPU not for DMA 1: The descriptor is available for DMA not for CPU
30	INTC	Interrupt on completion bit This is valid only when the last segment (TDES0[29]) is set. 0: TS bit in ENET_DMA_STAT is not set when frame transmission complete. 1: TS bit in ENET_DMA_STAT is set when frame transmission complete.
29	LSG	Last segment bit This bit indicates that the buffer contains the last segment of the frame. 0: The buffer of descriptor is not stored the last part of frame 1: The buffer of descriptor is stored the last part of frame
28	FSG	First segment bit This bit indicates that the buffer contains the first segment of a frame. 0: The buffer of descriptor is not stored the first block of frame 1: The buffer of descriptor is stored the first block of frame
27	DCRC	Disable CRC bit This is valid only when the first segment (TDES0[28]) is set. 0: The MAC automatic append a CRC to the end of the transmitted frame 1: The MAC does not append a CRC to the end of the transmitted frame
26	DPAD	Disable adding pad bit This is valid only when the first segment (TDES0[28]) is set. 0: The DMA automatically adds padding byte and CRC to a frame shorter than 64 bytes. Only the padding actually acts, the CRC is also appended. The DCRC bit is don't care. 1:The MAC does not automatically add padding to a frame
25	TTSEN	Transmit timestamp function enable bit. This field is only valid when the First segment control bit (TDES0[28]) is set. 0: Disable transmit timestamp function 1: When TMSEN is set (ENET_PTP_TSCTL bit 0), IEEE 1588 hardware time stamping is activated for the transmit frame
24	Reserved	Must be kept at reset value
23:22	CM[1:0]	Checksum mode bits 0x0: Disabled checksum insertion function 0x1: Only enable function for IP header checksum calculation and insertion 0x2: Enable IP header checksum and payload checksum calculation and insertion, pseudo-header checksum is not calculated in hardware 0x3: Enable IP Header checksum and payload checksum calculation and insertion, pseudo-header checksum is calculated in hardware.

21	TERM	Transmit end for ring mode bit This bit is used only in ring mode and has higher priority than TCHM 0: The current descriptor is not the last descriptor in the table 1: The descriptor table reached its final descriptor. The DMA descriptor pointer returns to the start address of the table.
20	TCHM	The second address chained mode bit This bit is used only in chain mode. When this bit, TCHM (TDES0[20]), is set, TB2S (TDES1[28:16]) is don't care. 0: The second address in the descriptor is the second buffer address 1:The second address in the descriptor is the next descriptor address
19:18	Reserved	Must be kept at reset value
17	TTMSS	Transmit timestamp status bit This bit is only valid when the descriptor's last segment (LSG) control bit (TDES0[29]) is set. 0: Timestamp was not captured 1:A timestamp was captured for the described transmit frame and push into TDES2 and TDES3.
16	IPHE	IP header error bit IP header error occurs when any case of below happen: IPv4 frames: 1) The header length field has a value less than 0x5. 2) The header length field value in transmitting IPv4 frame is mismatch with the number of header bytes 3) The version field value does not match the length/type field value IPv6 frames: 1) The main header length is not 40 bytes 2) The version field value does not match the length/type field value 0:The MAC transmitter did not detect error in the IP datagram header 1:The MAC transmitter detected an error in the IP datagram header
15	ES	Error summary bit Following bits are logical ORed to generate this bit: TDES0[16]: IP header error TDES0[14]: Jabber timeout TDES0[13]: Frame flush TDES0[12]: IP payload error TDES0[11]: Loss of carrier TDES0[10]: No carrier TDES0[9]: Late collision TDES0[8]: Excessive collision TDES0[2]:Excessive deferral TDES0[1]: Underflow error

14	JT	Jabber timeout bit Only set when the JBD bit is reset 0:No jabber timeout occurred 1:The MAC transmitter has experienced a jabber timeout
13	FRMF	Frame flushed bit This bit is set to flush the Tx frame by software
12	IPPE	IP payload error bit The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP or ICMP packet bytes received from the application and issues an error status in case of a mismatch 0:No IP payload error occurred 1: MAC transmitter detected an error in the TCP, UDP, or ICMPIP datagram payload
11	LCA	Loss of carrier bit When the interface signal 'CRS' lost one or more cycles and no collision happened during transmitting, the loss of carrier condition occurs. This is valid only in Half-duplex mode. 0:No loss of carrier occurred 1:A loss of carrier occurred during frame transmission
10	NCA	No carrier bit 0: PHY carrier sense signal is active 1: The carrier sense signal from the PHY was not asserted during transmission
9	LCO	Late collision bit If a collision occurs when 64 bytes (including preamble and SFD) has already transferred, this situation called late collision. 0: No late collision occurred 1: Late collision situation occurred **Note:** This bit is not valid if the UFE bit is set
8	ECO	Excessive collision bit If the RTD=1 (retry function disable), this bit is set after the first collision. If the RTD=0 (retry function enable), this bit is set when failed 16 successive retry transmitting. When this bit is set, the transmission of current frame is aborted. 0: No excessive collision occurred 1: Excessive collision occurred
7	VFRM	VLAN frame bit 0:The transmitted frame was a normal frame 1: The transmitted frame was a VLAN-type frame
6:3	COCNT[3:0]	Collision count bits

		This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the ECO bit (TDES0[8]) is set
2	EXD	Excessive deferral bit This is valid when the DFC bit in the MAC configuration register is set 0: No excessive deferral occurred 1: The transmission has ended because of excessive deferral time is over 3036 bytes
1	UFE	Underflow error bit This bit indicates that the TxDMA comes across an empty TxFIFO while transmitting the frame before EOF which is caused by pushing data to TxFIFO late from memory. The transmission process enters the suspend state and sets both the TU (bit 5) and the TS (bit 0) in ENET_DMA_STAT 0: No underflow error occurred 1: Underflow error occurred and the MAC aborted the frame transmitting
0	DB	Deferred bit This bit indicates whether the transmitting frame is deferred because of interface signal CRS is active before MAC transmit frame. Valid only in Half-duplex mode 0:No transmission deferred 1:The MAC is deferred before transmission

Bits	Fields	Descriptions
31:29	Reserved	Must be kept at reset value
28:16	TB2S[12:0]	Transmit buffer 2 size bits These bits indicate byte size of the second data buffer. This field is not valid if the TCHM bit (TDES0[20]) is set.
15:13	Reserved	Must be kept at reset value
12:0	TB1S[12:0]	Transmit buffer 1 size bits These bits indicate the byte size of the first data buffer. If this field is 0, the TxDMA ignores this buffer and uses buffer 2 (for TCHM=0) or the next descriptor (for TCHM=1).

■ TDES2: Transmit descriptor word 2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TB1AP/TTSL[31:16]															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TB1AP/TTSL[15:0]															
rw															

Bits	Fields	Descriptions
31:0	TB1AP/TTSL[31:0]	Transmit buffer 1 address pointer/Transmit frame timestamp low 32-bit value bits Before transmitting frame, application must configure these bits for transmit buffer 1 address (TB1AP). When the transmitting frame is complete, these bits can be changed to the timestamp low 32-bit value (TTSL) for transmitting frame. When these bits stand for buffer 1 address (TB1AP), the alignment is no limitation. When these bits stand for timestamp low 32-bit value, the TTSEN and LSG bit of current descriptor must be set.

■ TDES3: Transmit descriptor word 3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TB2AP/TTSH[31:16]															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TB2AP/TTSH[15:0]															
rw															

Bits	Fields	Descriptions
31:0	TB2AP/TTSH[31:0]	Transmit buffer 2 address pointer (or next descriptor address) / Transmit frame timestamp high 32-bit value bits Before transmitting frame, application must configure these bits for transmit buffer 2 address (TB2AP) or the next descriptor address which is decided by descriptor type is ring or chain. When the transmitting frame is complete, these bits can be changed to the timestamp high 32-bit value (TTSH) for transmitting frame TTSEN =1. When these bits stand for buffer 2 address (TCHM=0), the alignment is no limitation. When these bits stand for the next descriptor address (TCHM=1), these bits must be word-alignment. When these bits stand for timestamp high 32-bit value, the TTSEN and LSG bit of current descriptor must be set.

RxDMA configuration

The receiving process of the RxDMA controller is described detailed as below:

1. Applications initialize the receive descriptors with the DAV bit (RXDES0[31]) is set

2. Setting the SRE bit in ENET_DMA_CTL register to make RxDMA controller entering running state. In running state, the RxDMA controller continually fetching the receive descriptors from descriptor table whose starting address is configured in ENET_DMA_RDTADDR register by application. If the DAV bit of the fetched receive descriptor is set, then this descriptor is used for receiving frame. But if the DAV bit is reset which means this receive descriptor cannot be used by RxDMA, the RxDMA controller will enter suspend state and operation goes to Step 9

3. From the valid receive descriptor (DAV=1), the RxDMA controller marks the receiving control bit and data buffer address

4. Processing the received frames and transfer data to the receive buffer from the RxFIFO.

5. If all frame data has completely transferred or the buffer is full, the RxDMA controller fetches the next descriptor from receive descriptor table.

6. If the current receiving frame transfer is complete, the operation of RxDMA goes to Step7. But if not complete, two conditions may occur:

   1) The next descriptor's DAV bit is reset. The RxDMA controller sets descriptor error bit DERR in RDES0 if flushing function is enabled. The RxDMA controller closes current descriptor by resetting DAV bit and sets the LSG bit (if flushing is enabled) or resets the LSG bit (if flushing is disabled). Then the operation goes to Step 8.

   2) The next descriptor's DAV bit is set. The RxDMA controller closes current descriptor by resetting DAV bit and operation goes to Step 4.

7. If IEEE 1588 time stamping function is enabled, the RxDMA controller writes the time stamp value (if receiving frame meets the configured time stamping condition) to the current descriptor's RDES2 and RDES3. At the same time (writing timestamp value) the RxDMA controller also writes the received frame's status word to the RDES0 with the DAV bit cleared and the LSG bit set.

8. The latest descriptor is fetched by RxDMA controller. If the fetched descriptor bit 31 (DAV) is set, the RxDMA controller operation goes to Step 4. If the fetched descriptor bit 31 is reset, the RxDMA controller enters the suspend state and sets the RBU bit in register ENET_DMA_STAT. If flushing function is enabled, the RxDMA controller will flush the received frame data in the RxFIFO before entering suspend state.

9. In suspended state, there are two conditions to exit. The first is writing data in the ENET_DMA_RPEN register by application. The second is when a new received frame is available which means the byte number of receiving frame is greater than threshold in Cut-Through mode or when the whole frame is received in Store-and-Forward mode. Once exiting suspend mode, the RxDMA controller fetches the next descriptor and the following operation goes to Step 2.

Receive descriptor fetching regulation

Descriptor fetching occurs if any one or more of the following conditions are met:

- The time SRE bit is configured from 0 to 1 which makes the RxDMA controller entering running state
- The total buffer size (buffer 1 for chain mode or buffer 1 plus buffer 2 for ring mode) of the current descriptor cannot hold the current receiving frame. In other word, the last byte stored in buffer space is not the EOF byte
- After a complete frame is transferred to buffer and before current descriptor is closed
- In suspend state, the MAC received a new frame
- Writing any value to receive poll enable register ENET_DMA_RPEN

Process of receiving frame

When a frame is presented on the interface, the MAC starts to receive it. At the same time, the address filter block is running for this received frame. If the received frame fails the address filtering it will be discarded from RxFIFO in MAC and not be forwarded to buffer by RxDMA controller. If the received frame passes the address filtering, it will be forwarded to buffer when the available time comes. If the RxDMA controller is configured in Cut-Through mode, the available time means the byte number of the received frame is equal or greater than the configured threshold. If the RxDMA controller is configured in Store-and-Forward mode, the available time means the complete frame is stored in RxFIFO. During receiving frame, if any one of the below cases occurs the MAC can discard the received frame data in RxFIFO and the RxDMA controller will not forward these data: 1) The received frame bytes is less than 64. 2) Collision occurred during frame receiving. 3) The premature termination for the receiving frame.

When the available time comes, the RxDMA controller starts transfer frame data from RxFIFO to the receive buffer. If the SOF is included in current receive buffer, the FDES bit in RDES0 is set when the RxDMA controller writing receive frame status to indicate this descriptor is used for storing the first part of the frame. If the EOF is included in current receive buffer, the LDES bit in RDES0 is set when RxDMA controller writing receive frame status to indicate this descriptor is used for storing the last part of the frame. Often when the buffer size is larger than received frame, the FDES and LDES bit are set in the same descriptor. When the EOF is transferred to buffer or the receive buffer space is exhausted, the RxDMA controller fetches the next receive descriptor and closes previous descriptor by writing RDES0 with DAV=0. If the LDES bit is set, the other status are also be updated and the RS bit in ENET_DMA_STAT register will be set when DINTC=0 or not when DINTC=1. If the DAV bit of the next descriptor is set, the RxDMA controller repeats above operation when received a new frame. If the DAV bit of the next descriptor is reset, the RxDMA controller enters suspend state and sets RBU bit in ENET_DMA_STAT register. The pointer value of descriptor address table is retained and be used for the starting descriptor address after exiting suspend state.

Processing after a new frame received in suspend state

When a new frame is available (see available definition in the previous paragraph), the RxDMA controller fetches the descriptor. If the DAV bit in RDES0 is set, the RxDMA controller exits suspend state and returns to running state for frame reception. But if the DAV bit in RDES0 is reset, application can choose whether these received frame data in RxFIFO are flushed or not by configuring DAFRF bit in ENET_DMA_CTL register. If DAFRF=0, the RxDMA controller discards these received frame data and makes the missed frame counter (MSFC) increase one. If DAFRF=1, these frame data are will not be flushed and MSFC counter will not increase until the RxFIFO is full. If the DAV bit is reset in fetched descriptor, the RBU bit in ENET_DMA_STAT register will be set and the RxDMA controller will be still in suspend state.

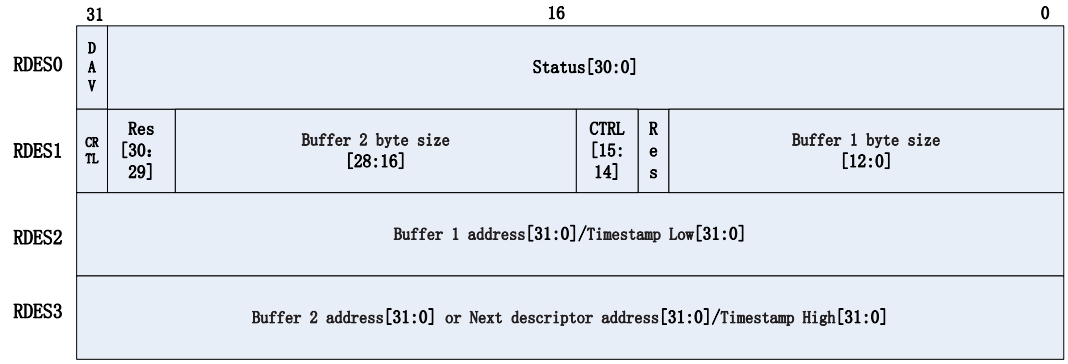
Receive DMA descriptor with IEEE 1588 timestamp format

If the IEEE 1588 function enabled, the MAC writes the timestamp value to RDES2 and RDES3 after a frame with timestamp reception complete and before the RxDMA controller clears the DAV bit.

RxDMA descriptors

In normal descriptor mode, the descriptor structure consists of four 32-bit words: RDES0 ~ RDES3. The detailed description of RDES0, RDES1, RDES2 and RDES3 are given below.

Figure 27-10. Receive descriptor



■ RDES0: Receive descriptor word 0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DAV	DAFF	FRML[13:0]													
rw	rw	rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERRS	DERR	SAFF	LERR	OERR	VTAG	FDES	LDES	IPHERR/TSV	LCO	FRMT	RWDT	RERR	DBERR	CERR	PCERR/EXSV
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits	Fields	Descriptions
31	DAV	Descriptor available bit

		This bit indicates the DMA controller can use this descriptor. The DMA clears this bit either when it completes the frame reception or when the buffers in this descriptor are full 0: The descriptor is owned by the CPU 1: The descriptor is owned by the DMA
30	DAFF	Destination address filter fail bit 0: A frame passed the destination address filter 1: A frame failed the destination address filter
29:16	FRML[13:0]	Frame length bits These bits indicate the byte length of the received frame that was transferred to the buffer (including CRC). This field is valid only when LDES=1 (RDES0[8]) and DERR=0 (RDES0[14]). If LDES=0 and ERRS=0, these bits indicate the accumulated number of bytes that have been transferred for the current frame.
15	ERRS	Error summary bit This field is valid only when the LDES (RDES0[8]) is set. This bit is logical ORed by the following bits: RDES0[14]: Descriptor error. RDES0[11]: Overflow error RDES0[7]: IP frame header error RDES0[6]: Late collision RDES0[4]: Watchdog timeout RDES0[3]: Receive error RDES0[1]: CRC error
14	DERR	Descriptor error bit This field is valid only when the LDES (RDES0[8]) is set. When the current buffer cannot hold current received frame and the next descriptor's DAV bit is reset, the descriptor error occurs. 0: No descriptor error occurred 1: Descriptor error occurred
13	SAFF	SA filtering fail bit 0: No source address filter fail occurred 1: A received frame failed the SA filter
12	LERR	Length error bit This bit is valid only when the FRMT (RDES0[5]) bit is reset. This bit indicates the mismatch between the length field in received and the actual frame length. 0: No length error occurred 1: Length error occurred
11	OERR	Overflow error bit

		When RxFIFO is overflow and the frame data has been partly forwarded to descriptor buffer, the overflow error bit sets. 0: No overflow error occurred 1: RxFIFO overflowed and frame data is not valid
10	VTAG	VLAN tag bit 0: Received frame is not a tag frame 1: Received frame is a tag frame
9	FDES	First descriptor bit This bit indicates that current descriptor contains the SOF of the received frame. 0: The current descriptor does not store the SOF of the received frame 1: The current descriptor buffer saves the SOF of the received frame
8	LDES	Last descriptor bit This bit indicates that current descriptor contains the EOF of the received frame 0: The current descriptor buffer does not store EOF of the received frame 1: The current descriptor buffer saves the EOF of the received frame
7	IPHERR	IP frame header checksum error bit This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. 0: No IPv header checksum error occurred 1: An error in the IPv4 or IPv6 header
6	LCO	Late collision bit This bit indicates a collision occurs after 64 bytes have been received This bit only valid in Half-duplex mode. 0: No late collision occurred 1: Late collision has occurred
5	FRMT	Frame type bit This bit is not valid for Runt frames less than 14 bytes. 0: The received frame is an IEEE802.3 frame 1: The receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600)
4	RWDT	Receive watchdog timeout bit When WDD=0, this bit indicates a frame with more than 2048 bytes was detected. When WDD=1, this bit indicates a frame with more than 16384 bytes was detected. 0: No receive watchdog timeout occurred 1: Watchdog timer overflowed during receiving and current frame is only a part of frame.
3	RERR	Receive error bit This bit indicates the interface signal RX_ER asserted when RX_DV signal is active during frame receiving process.

0: No receive error occurred
1: Receive error occurred

2 DBERR Dribble bit error bit
This bit is valid only in MII interface mode and indicates there is an incomplete byte (odd cycles during reception) received.
0: No dribble bit error occurred
1: Dribble bit error occurred

1 CERR CRC error bit
This bit is valid only when the LDES (RDES0[8]) is set and indicates FCS field in received frame is mismatch with the calculation result of the hardware
0: No CRC error occurred
1: A CRC error occurred

0 PCERR Payload checksum error bit
0: No payload checksum error occurred
1: The TCP, UDP or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP or ICMP segment's Checksum field or when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame.

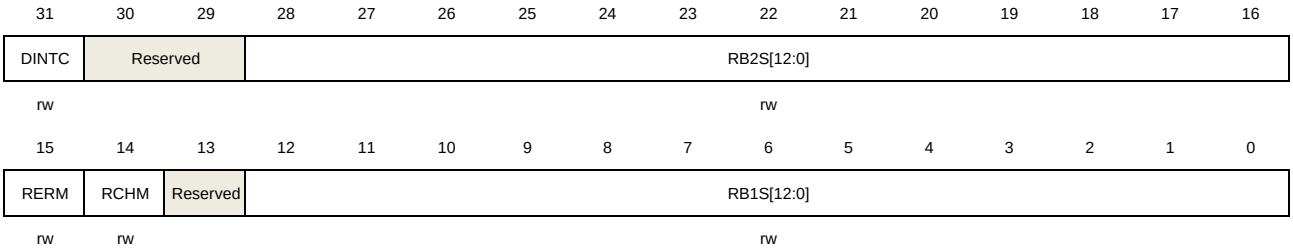
The following table shows the combination meaning for bit 7, 5, and 0 in RDES0:

Table 27-6. Error status decoding in RDES0, only used for normal descriptor

Bit 7: IPHERR	Bit 5: FRMT	Bit 0: PCERR	Frame status
0	0	0	IEEE 802.3 normal frame (Length field value is less than 0x0600 and not tagged)
0	0	1	IPv4 or IPv6 frame, no header checksum error, payload checksum is bypassed because of unsupported payload type
0	1	0	IPv4 or IPv6 frame, checksum checking pass
0	1	1	IPv4 or IPv6 frame, payload checksum error. This error may cased by following condition: 1) Calculated checksum value mismatch the checksum field 2) byte number of received payload mismatch length field
1	0	0	Reserved
1	0	1	A type (length/type field equal or greater than 0x0600) or tagged frame but neither IPv4 nor IPv6. Offload check engine is bypassed.
1	1	0	IPv4 or IPv6 frame, but an header checksum error detected This error may cased by following condition: 1) Type value inconsistent with version value 2) Calculated header checksum mismatch the header checksum field 3) Expected IP header bytes is not received enough

1	1	1	IPv4 or IPv6 frame, both header and payload checksum detected errors

- RDES1: Receive descriptor word 1



Bits	Fields	Descriptions
31	DINTC	Disable interrupt on completion bit 0: RS bit in ENET_DMA_STAT register will be set after receiving the completed, then if enabled the corresponding interrupt, the interrupt will trigger. 1: RS bit in ENET_DMA_STAT register will not be set after receiving the completed, so the corresponding interrupt will not be triggered.
30:29	Reserved	Must be kept at reset value
28:16	RB2S[12:0]	Receive buffer 2 size bits The second buffer size in bytes. The buffer size must be a multiple of 4. This field is ignored if RCHM (RDES1[14]) is set
15	RERM	Receive end of ring mode bit This bit indicates the final descriptor in table is arrived and the next descriptor address is automatically set to the configured start descriptor address. 0: Current descriptor is not the last descriptor in table 1: Current descriptor is the last descriptor in table
14	RCHM	Receive chained mode for second address bit 0: The second address points to the second buffer address. 1: The second address points to the next descriptor address. RB2S (RDES1[28:16]) is ignored. **Note:** If the RERM=1, the next descriptor returns to base address even this bit is set to 1.
13	Reserved	Must be kept at reset value
12:0	RB1S[12:0]	Receive buffer 1 size bits The first buffer size in bytes. The buffer size must be a multiple of 4. If this field is 0, the RxDMA controller ignores this buffer and uses buffer 2 (RCHM=0) or the next descriptor (RCHM=1)

- RDES2: Receive descriptor word 2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RB1AP/RTSL[31:16]															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RB1AP/RTSL[15:0]															
rw															

Bits	Fields	Descriptions
31:0	RB1AP/RTSL[31:0]	Receive buffer 1 address pointer / Receive frame timestamp low 32-bit These bits are designed for two different functions: buffer address pointer (RB1AP) or timestamp low 32-bit value (RTSL). **RB1AP**: Before fetching this descriptor by RxDMA controller, these bits are configured to the buffer 1 address by application. This buffer 1 address pointer is used for RxDMA controller to store the received frame if RB1S is not 0. The buffer address alignment has no limitation. **RTSL**: When timestamp function is enabled and LDES is set, these bits will be changed to timestamp low 32-bit value by RxDMA controller if received frame passed the filter and satisfied the snapshoot condition. If the received frame does not meet the snapshoot condition, these bits will keep RB1AP value.

- RDES3: Receive descriptor word 3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RB2AP/RTSH[31:16]															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RB2AP/RTSH[15:0]															
rw															

Bits	Fields	Descriptions
31:0	RB2AP/RTSH[31:0]	Receive buffer 2 address pointer (next descriptor address) / Receive frame timestamp high 32-bit value bits These bits are designed for two different functions: buffer address pointer or next descriptor address (RB1AP) or timestamp high 32-bit value (RTSH). **RB2AP**: Before fetching this descriptor by RxDMA controller, these bits are configured to the buffer 2 address (RCHM=0) or the next descriptor address (RCHM=1) by application. This buffer 2 address pointer is used for RxDMA controller to store the received frame if RB1S is not 0 when RCHM=0. If RCHM=1 and RERM=0, this address pointer is used for fetching the next descriptor. If RCHM=1 and RERM=1, these bits are ignored. When this address is used for next descriptor address, the word alignment is needed. The other conditions have no limitation for these bits. **RTSH**: When timestamp function is enabled and LDES is set, these bits will be changed to timestamp high 32-bit value by RxDMA controller if received frame

passed the filter and satisfied the snapshoot condition. If the received frame does not meet the snapshoot condition, these bits will keep RB2AP value.

27.3.7. Example for a typical configuration flow of Ethernet

After power-on reset or system reset, the following operation flow is a typical process for application to configure and run Ethernet:

- **Enable Ethernet clock.**

Program the RCU module to enable the HCLK and Ethernet Tx/Rx clock.

- **Setup the communication interface.**

  Configure AFIO_PCF0 to define which interface mode is selected (MII or RMII). Configure GPIO module to make selected PADs to alternate function.

- **Wait the resetting complete**

  Polling the ENET_DMA_BCTL register until the SWR bit is reset. (SWR bit is set by default after power-on reset or system reset)

- **Obtain and configure the parameters in PHY register**

  According to the frequency of HCLK, configure the SMI clock frequency and access external PHY register to obtain the information of PHY (e.g. support Half/Full duplex or not, support 10M/100Mbit speed or not, and so on). Based on supported mode of external PHY, configure ENET_MAC_CFG register consistent with PHY register.

- **Initialize the DMA in Ethernet module for transaction**

  Configure the ENET_DMA_BCTL, ENET_DMA_RDTADDR, ENET_DMA_TDTADDR, ENET_DMA_CTL registers to initialize the DMA module. (Detailed information refer to ***DMA controller description***)

- **Initialize the physical memory space for descriptor table and data buffer**

  According to the address value in ENET_DMA_RDTADDR and ENET_DMA_TDTADDR register, program transmitting and receiving descriptors (with DAV=1) and data buffer.

- **Enable MAC and DMA module to start transmit and receive**

  Set TEN and REN bit in ENET_MAC_CFG register to make MAC work for transmit and receive. Set STE and SRE bit in ENET_DMA_CTL register to make DMA controller work for transmit and receive.

- **If transmitting frames is needed**

  1) Choose one or more programmed transmitting descriptor, write the transmit frame data into buffer address which is decided in TDES.

  2) Set the DAV bit in these one or more transmit frame descriptor.

3) Write any value in ENET_DMA_TPEN register to make TxDMA exit suspend state and start transmitting

4) There are two methods for application to confirm whether current transmitting frame is complete or not. The first method is that application can poll the DAV bit of current transmit descriptor until it is reset, this means the transmitting is complete. The second method can be used only when INTC=1. Application can poll the TS bit in ENET_DMA_STAT register until it is set, this means the transmitting is complete.

- **If receiving frames is enabled**

1) Check the first receive descriptor in descriptor table (whose address is configured in ENET_DMA_RDTADDR register).

2) If DAV bit in RDES0 is reset, then the descriptor is used and receive buffer space has stored the receive frame.

3) Handling this receive frame data.

4) Set DAV bit of this descriptor to release this descriptor for new frame receiving.

5) Check next descriptor in table, then goes to Step 2.

27.3.8. Ethernet interrupts

There are two interrupt vectors in Ethernet module. The first interrupt vector is made up of normal operation interrupts and the second vector is made up of WUM events for wakeup which is mapped to the EXTI line 19.

All of the MAC and DMA controller interrupt are connected to the first interrupt vector. The description for the MAC interrupt and DMA controller interrupt are showed behind.

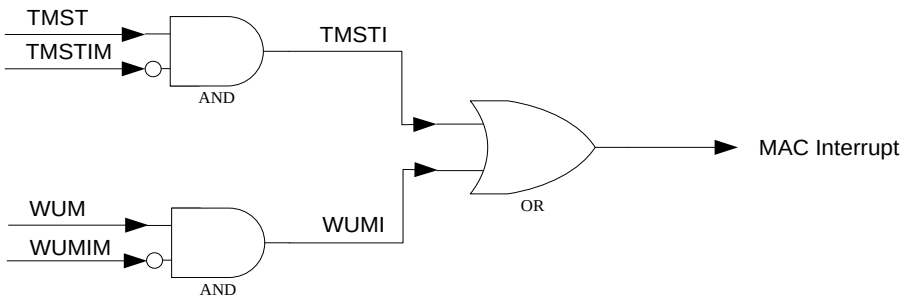
The WUM block event is connected to the second interrupt vector. The event can be remote wakeup frame received event or/and Magic Packet wakeup frame received event. This interrupt is inner mapped on the EXTI line 19. So, if the EXTI line 19 is enabled and configured to trigger by rising edge, the Ethernet WUM event can make the system exiting Deep-sleep mode after a WUM event occurred. In addition, if the WUM interrupt is not masked, both the EXTI line 19 interrupt and Ethernet normal interrupt to CPU are both generated.

Note: Because of the WUM registers are designed in RX_CLK domain, clear these registers by reading them will need a long time delay (depends on the frequency disparity between HCLK and RX_CLK). To avoid entering the same event interrupt twice, it's strongly recommended that application polls the WUFR and MPKR bit until they reset to zero during the interrupt service routine.

MAC interrupts

All of the MAC events can be read from ENET_MAC_INTF and each of them has a mask bit for masking corresponding interrupt. The MAC interrupt is logical ORed of all interrupts.

Figure 27-11. MAC interrupt scheme



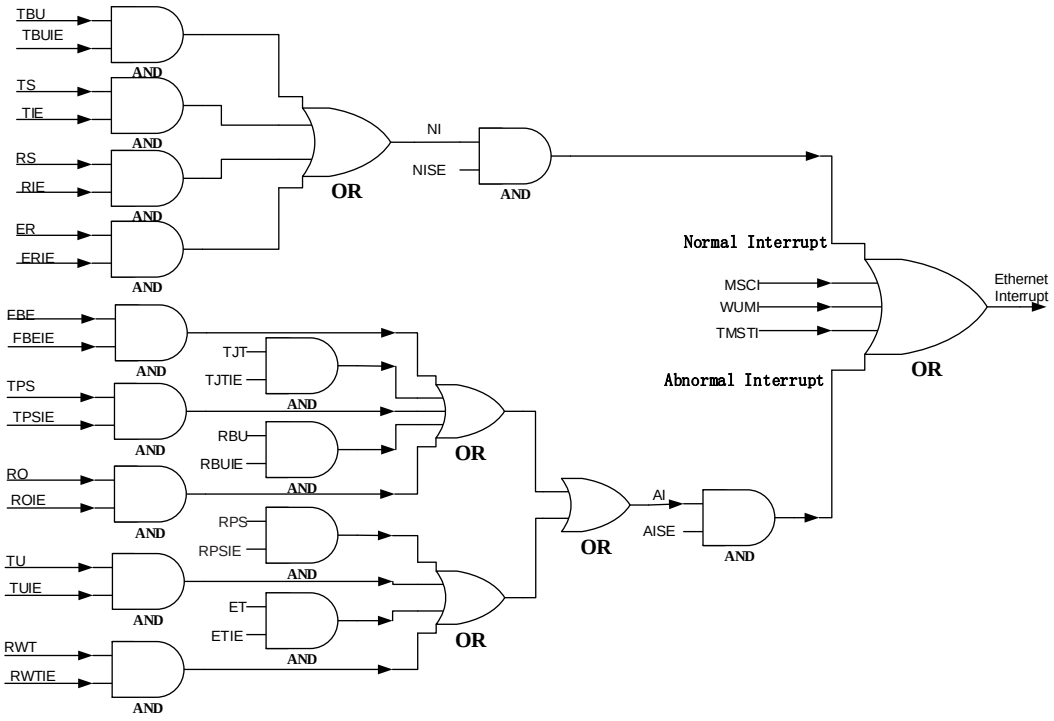
DMA controller interrupts

The DMA controller has two types of event: Normal and Abnormal.

No matter what type the event is, it has an enable bit (just like mask bit) to control the generating interrupt or not. Each event can be cleared by writing 1 to it. When all of the events are cleared or all of the event enable bits are cleared, the corresponding summary interrupt bit is cleared. If both normal and abnormal interrupts are cleared, the DMA interrupt will be cleared.

Below block diagram illustrates the Ethernet module interrupt connection:

Figure 27-12. Ethernet interrupt scheme



27.4. Register definition

Byte (8-bit) access, half word (16-bit) access and word (32-bit) access are all supported for application.

ENET start address: 0x4002 8000

27.4.1. MAC configuration register (ENET_MAC_CFG)

Address offset: 0x0000
Reset value: 0x0000 8000

This register configures the operation mode of the MAC. It also configures the MAC receiver and MAC transmitter operating mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								WDD	JBD	Reserved		IGBS[2:0]			CSD
								rw	rw				rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	SPD	ROD	LBM	DPM	IPFCO	RTD	Reserved	APCD	BOL[1:0]		DFC	TEN	REN	Reserved	
	rw	rw	rw	rw	rw	rw		rw	rw		rw	rw	rw		

Bits	Fields	Descriptions
31:24	Reserved	Must be kept at reset value
23	WDD	Watchdog disable bit This bit indicates the maximum bytes for receiving, data beyond this will be cut off. 0: The MAC allows no more than 2048 bytes of the frame being received 1: The MAC disables the watchdog timer on the receiver, and can receive frames of up to 16384 bytes
22	JBD	Jabber disable bit This bit indicates the maximum bytes for transmitting data, data beyond this will be cut off. 0: The maximum transmission byte is 2048 1: The maximum transmission byte can be 16384
21:20	Reserved	Must be kept at reset value
19:17	IGBS[2:0]	Inter frame gap bit selection bits These bits can select the minimum inter frame gap bit time between two neighboring frames during transmission. 0x0: 96 bit times 0x1: 88 bit times 0x2: 80 bit times 0x3: 72 bit times

		0x4: 64 bit times 0x5: 56 bit times(For Half-duplex, must be reserved) 0x6: 48 bit times(For Half-duplex, must be reserved) 0x7: 40 bit times(For Half-duplex, must be reserved)
16	CSD	Carrier sense disable bit 0: The MAC transmitter generates carrier sense error and aborts the transmission 1: The MAC transmitter ignores the MII CRS signal during frame transmission in Half-duplex mode. Loss of carrier error and no carrier error will not be generated.
15	Reserved	Must be kept at reset value
14	SPD	Fast Ethernet speed bit Indicates the speed in Fast Ethernet mode: 0: 10 Mbit/s 1: 100 Mbit/s
13	ROD	Receive own disable bit This bit is not applicable if the MAC is operating in Full-duplex mode 0: The MAC receives all packets that are given by the PHY while transmitting 1: The MAC disables the reception of frames in Half-duplex mode
12	LBM	Loopback mode bit 0: The MAC operates in normal mode 1: The MAC operates in loopback mode at the MII.
11	DPM	Duplex mode bit 0: Half-duplex mode enable 1: Full-duplex mode enable
10	IPFCO	IP frame checksum offload bit 0: The checksum offload function in the receiver is disabled 1: IP frame checksum offload function enabled for received IP frame
9	RTD	Retry disable bit This bit is applicable only in the Half-duplex mode 0: The MAC attempts retries up to 16 times based on the settings of BOL 1: The MAC attempts only 1 transmission.
8	Reserved	Must be kept at reset value
7	APCD	Automatic pad/CRC drop bit This bit only valid for a non tagged frame and its length field value is equal or less than 1536. 0: The MAC forwards all received frames without modify it 1: The MAC strips the Pad/FCS field on received frames
6:5	BOL[1:0]	Back-off limit bits

		When a collision occurred, the MAC needs to retry sending current frame after delay some time. The base time unit for this delay time (dt) called slot time which means 1 slot time is equal to 512 bit times. This delay time (dt) is a random integer number calculated by following formula : $0 \leqslant dt < 2^k$ 0x0: k = min (n, 10) 0x1: k = min (n, 8) 0x2: k = min (n, 4) 0x3: k = min (n, 1), n = number of times for retransmission attempt **Note:** This bit is valid only in Half-duplex mode
4	DFC	Deferral check bit 0: The deferral check function is disabled. MAC defers sending until the CRS goes inactive. 1: The deferral check function is enabled in the MAC. If deferred more than 24288 bit times, excessive deferral error occurs and MAC abort transmitting frame. If CRS signal active during deferral time running, the deferral time will reset and restart. **Note:** This bit is valid only in Half-duplex mode
3	TEN	Transmitter enable bit 0:The MAC transmit function is disabled after finish the transmission of the current frame, and no frames to be transmitted anymore 1: The transmit function of the MAC is enabled for transmission
2	REN	Receiver enable bit 0: The MAC reception function is disabled after finish the reception of the current frame, and no frames will be received anymore. 1: The MAC reception function is enabled for receiving frames
1:0	Reserved	Must be kept at reset value

27.4.2. MAC frame filter register (ENET_MAC_FRMF)

Address offset: 0x0004
Reset value: 0x0000 0000

This register configures the filtering method for receiving frames

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FAR	Reserved														
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					HPFLT	SAFLT	SAIFLT	PCFRM[1:0]		BFRMD	MFD	DAIFLT	HMF	HUF	PM
					rw	rw	rw	rw		rw	rw	rw	rw	rw	rw

Bits	Fields	Descriptions
31	FAR	Frames all receive bit This bit controls the receive filter function. 0: Only the frame passed the filter can be forwarded to application. 1: All received frame are forwarded to application. But filter result will also be updated to receive descriptor status.
30:11	Reserved	Must be kept at reset value
10	HPFLT	Hash or perfect filter bit 0: If the HUF or HMF bit is set, only frames that match the hash filter are passed 1: If the HUF or HMF bit is set, the receive filter passes frames that match either the perfect filtering or the hash filtering
9	SAFLT	Source address filter bit Enable source address filtering function besides destination address filtering. The filter also compares the SA field value in received frames with the values configured in the enabled SA registers. If SA comparison matches, the SA match bit in the receive descriptor status is set high 0: Source address function in filter disable 1: Source address function in filter enable
8	SAIFLT	Source address inverse filtering bit This bit makes the result of SA matching inverse. 0: Not inverse for source address filtering 1: Inverse source address filtering result. When SA matches the enabled SA registers, filter marks it as failing the SA address filter
7:6	PCFRM[1:0]	Pass control frames bits These bits set the forwarding conditions for all control frames (including unicast and multicast pause frame). For pause control frame, the processing (not forwarding) depends only on RFCEN in ENET_MAC_FCTL[2] 0x0: MAC prevents all control frames from reaching the application 0x1: MAC only forwards all other control frames except pause control frame 0x2: MAC forwards all control frames to application even if they fail the address filter 0x3: MAC forwards control frames that only pass the address filter
5	BFRMD	Broadcast frames disable bit 0:The address filters pass all received broadcast frames 1:The address filters filter all incoming broadcast frames
4	MFD	Multicast filter disable bit 0:Filtering of multicast frame depends on the HMF bit 1:All received frames with a multicast destination address (first bit in the destination address field is '1' and not all bits in the destination are ‘1’) are passed

3	DAIFLT	Destination address inverse filtering bit This bit makes the result of DA filtering inverse 0: Not inverse DA filtering result 1: Inverse DA filtering result
2	HMF	Hash multicast filter bit 0: The filter uses perfect mode for filtering multicast frame. 1: The filter uses hash mode for filtering multicast frame
1	HUF	Hash unicast filter bit 0: The filter uses perfect mode for filtering unicast frame 1: The filter uses hash mode for filtering unicast frame
0	PM	Promiscuous mode bit This bit can make the filter bypassed which means all received frames are thought pass the filer and DA/SA filtering result status in descriptor is always '0'. 0: Promiscuous mode disabled 1: Promiscuous mode enabled

27.4.3. MAC hash list high register (ENET_MAC_HLH)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HLH[31:16]															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HLH[15:0]															
rw															

Bits	Fields	Descriptions
31:0	HLH[31:0]	Hash list high bits These bits take the high 32-bit value of hash list

27.4.4. MAC hash list low register (ENET_MAC_HLL)

Address offset: 0x000C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HLL[31:16]															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HLL[15:0]															

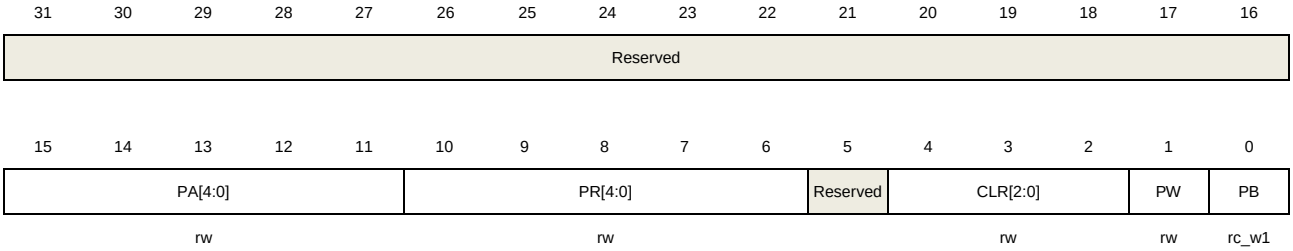
rw

Bits	Fields	Descriptions
31:0	HLL[31:0]	Hash list low bits These bits take the low 32-bit value of hash list

27.4.5. MAC PHY control register (ENET_MAC_PHY_CTL)

Address offset: 0x0010

Reset value: 0x0000 0000



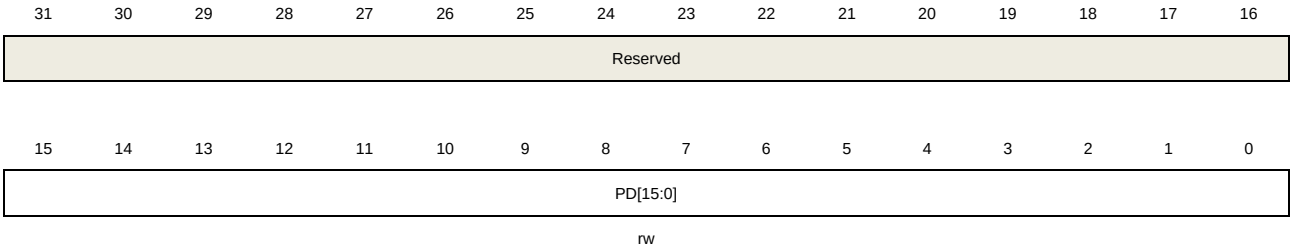
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:11	PA[4:0]	PHY address bits These bits choose which PHY device is to be accessed
10:6	PR[4:0]	PHY register bits These bits choose the register address in selected PHY device
5	Reserved	Must be kept at reset value
4:2	CLR[2:0]	Clock range bits MDC clock divided factor select which is decided by HCLK frequency range 0x0: HCLK/42 (HCLK range: 60-100 MHz) 0x1: HCLK/62 (HCLK range: 100-120 MHz) 0x2: HCLK/16 (HCLK range: 20-35 MHz) 0x3: HCLK/26 (HCLK range: 35-60 MHz) other: Reserved
1	PW	PHY write bit This bit indicate the PHY operation mode 0: Sending read operation to PHY 1: Sending write operation to PHY
0	PB	PHY busy bit This bit indicates the running state of operation on PHY. Application sets this bit to 1 and should wait it cleared by hardware. Application must make sure this bit is

zero before writing data to ENET_MAC_PHY_CTL register and reading/writing data from/to ENET_MAC_PHY_DATA register

27.4.6. MAC MII data register (ENET_MAC_PHY_DATA)

Address offset: 0x0014

Reset value: 0x0000 0000



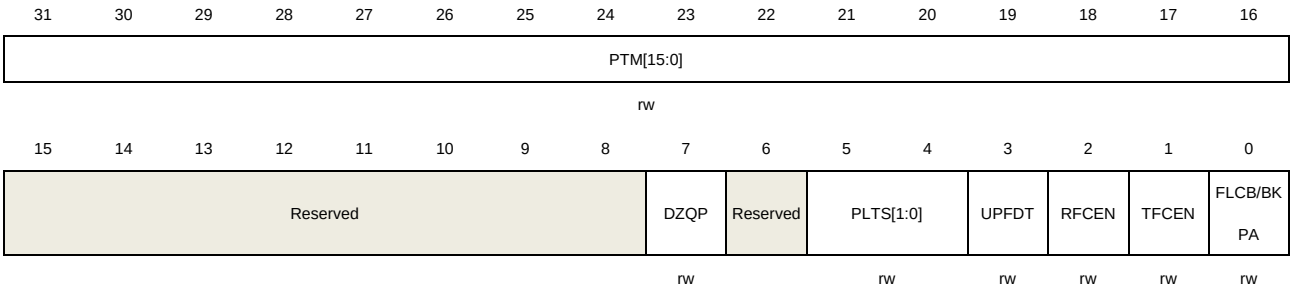
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value
15:0	PD[15:0]	PHY data bits For reading operation, these bits contain the data from external PHY. For writing operation, these bits contain the data will be sent to external PHY.

27.4.7. MAC flow control register (ENET_MAC_FCTL)

Address offset: 0x0018

Reset value: 0x0000 0000

This register configures the generation and reception of the control frames.



Bits	Fields	Descriptions
31:16	PTM[15:0]	Pause time bits These bits configured the pause time filed value in transmit pause control frame.
15:8	Reserved	Must be kept at reset value
7	DZQP	Disable Zero-quanta pause bit

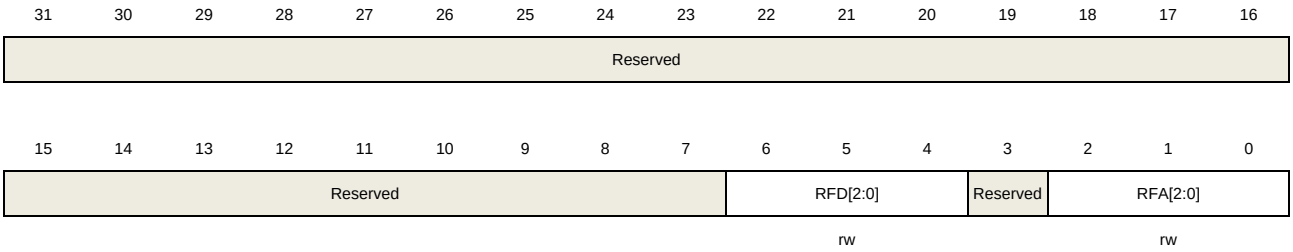
		0: Enable automatic zero-quanta generation function for pause control frame. 1: Disable the automatic zero-quanta generation function for pause control frame
6	Reserved	Must be kept at reset value
5:4	PLTS[1:0]	Pause low threshold bits These bits configure the threshold of the pause timer for retransmitting frames automatically. Application must make sure the low threshold bits are greater than 0 and less than configured pause time. The low threshold calculation formula is PTM-PLTS. For example, if PTM = 0x80 (128 slot-times), and PLTS = 0x1 (28 slot-times), then the second pause frame is automatically transmitted when pause timer counted at 100 (128 - 28) slot-times after the first pause frame is transmitted 0x0: Pause time minus 4 slot times 0x1: Pause time minus 28 slot times 0x2: Pause time minus 144 slot times 0x3: Pause time minus 256 slot times **Note:** One slot time equals the time of transmitting 512 bits on the MII interface
3	UPFDT	Unicast pause frame detect bit 0: Only the unique multicast address for pause frame which is specified in IEEE802.3 can be detected. 1: Besides the unique multicast address, MAC can also use the MAC0 address (ENET_MAC_ADDR0H and ENET_MAC_ADDR0L register) to detecting pause frame.
2	RFCEN	Receive flow control enable bit 0: Decode function for pause frame is disabled 1: Enable decoding function for the received pause frame and process it. The MAC disables its transmitter for a specified (pause time field value in received frame) time
1	TFCEN	Transmit flow control enable bit 0: Disable the flow control operation in the MAC. Both pause frame sending in Full-duplex mode and back-pressure feature in Half-duplex mode are not performed. 1: Enable the flow control operation in the MAC. Both pause frame sending in Full-duplex mode and back-pressure feature in Half-duplex mode can be performed by transmitter.
0	FLCB/BKPA	Flow control busy/back pressure activate bit This bit only valid when TFCEN is set. This bit can send a pause frame in Full-duplex mode or activate the back pressure function in Half-duplex mode by application. For Full-duplex mode, application must make sure this bit is 0 before writing ENET_MAC_FCTL register. After set by application, MAC sends a pause frame to interface and this bit will keep set until the pause frame has completed transmitting.

For Half-duplex mode, MAC can enter back-pressure state by application setting this bit. When the MAC is in back-pressure state, any frame presented on interface will make the MAC send a JAM pattern to inform outside a collision occurred.

27.4.8. MAC flow control threshold register (ENET_MAC_FCTH)

Address offset: 0x1080

Reset value: 0x0000 0015



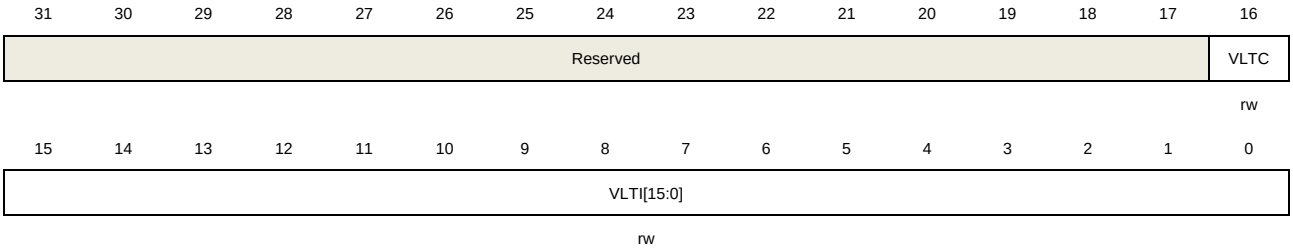
Bits	Fields	Descriptions
31:7	Reserved	Must be kept at reset value
6:4	RFD[2:0]	Threshold of deactive flow control This field configures the threshold of the deactive flow control. The value should always be less than the Threshold of active flow control value configured in bits[2:0]. When the value of the unprocessed data in RxFIFO is less than this value configured, the flow control function will deactive. 0x0: 256 bytes 0x1: 512 bytes 0x2: 768 bytes 0x3: 1024 bytes 0x4: 1280 bytes 0x5: 1536 bytes 0x6,0x7: 1792 bytes
3	Reserved	Must be kept at reset value
2:0	RFA[2:0]	Threshold of active flow control This field configures the threshold of the active flow control. If flow control function is enabled, when the value of the unprocessed data in RxFIFO is more than this value configured, the flow control function will active. 0x0: 256 bytes 0x1: 512 bytes 0x2: 768 bytes 0x3: 1024 bytes 0x4: 1280 bytes 0x5: 1536 bytes

0x6,0x7: 1792 bytes

27.4.9. MAC VLAN tag register (ENET_MAC_VLT)

Address offset: 0x001C
Reset value: 0x0000 0000

This register configures the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th byte (length/type field) of the receiving frame with 0x8100, and the following 2 bytes (the 15th and 16th byte) are compared with the VLAN tag.



Bits	Fields	Descriptions
31:17	Reserved	Must be kept at reset value
16	VLTC	12-bit VLAN tag comparison bit This bit selects 12 or 16 bit VLAN tag for comparison. 0: All 16 bits (the 15th and 16th byte) of the VLAN tag in received frame are used for comparison. 1: Only low 12 bits of the VLAN tag in received frame are used for comparison.
15:0	VLTI[15:0]	VLAN tag identifier (for receive frames) bits These bits are configured for detecting VLAN frame using 802.1Q VLAN tag format. The format shows below: VLTI[15:13]: UP(user priority) VLTI[12]: CFI(canonical format indicator) VLTI[11:0]: VID(VLAN identifier) When comparison bits (VLTI[11:0] if VLTC=1 or VLTI[15:0] if VLTC=0) are all zeros, VLAN tag comparison is bypassed and every frame with type filed value of 0x8100 is considered a VLAN frame. When comparison bits not all zeros, VLAN tag comparison use bit VLTI[11:0] (if VLTC=1) or VLTI[15:0] (if VLTC=0) for checking.

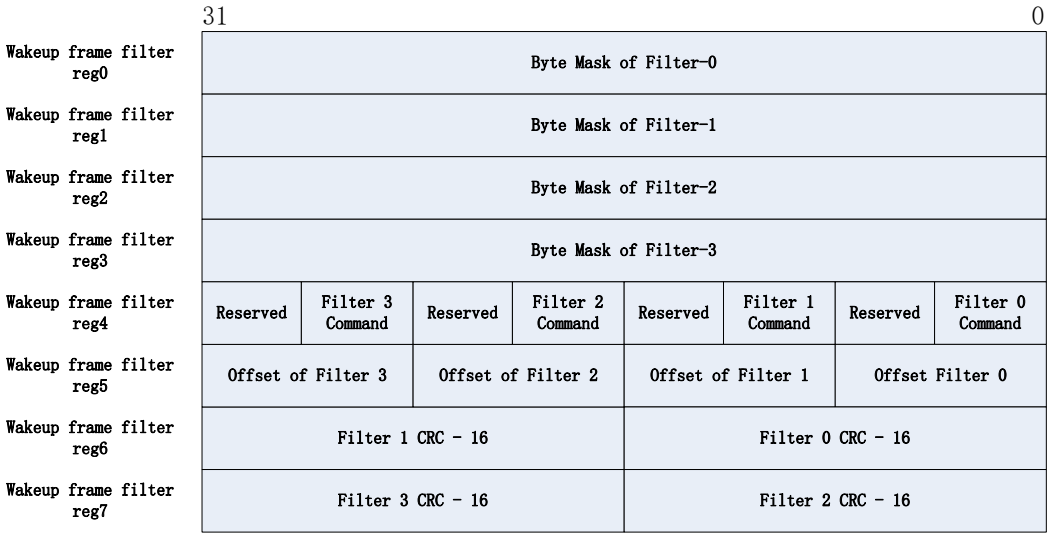
27.4.10. MAC remote wakeup frame filter register (ENET_MAC_RWFF)

Address offset: 0x0028
Reset value: 0x0000 0000

The MAC remote wakeup frame filter register is actually a pointer to eight (with same address

offset) such wakeup frame filter registers. Eight sequential write operations to this address with the offset (0x0028) will write all wakeup frame filter registers. Eight sequential read operations from this address with the offset (0x0028) will read all wakeup frame filter registers.

Figure 27-13. Wakeup frame filter register

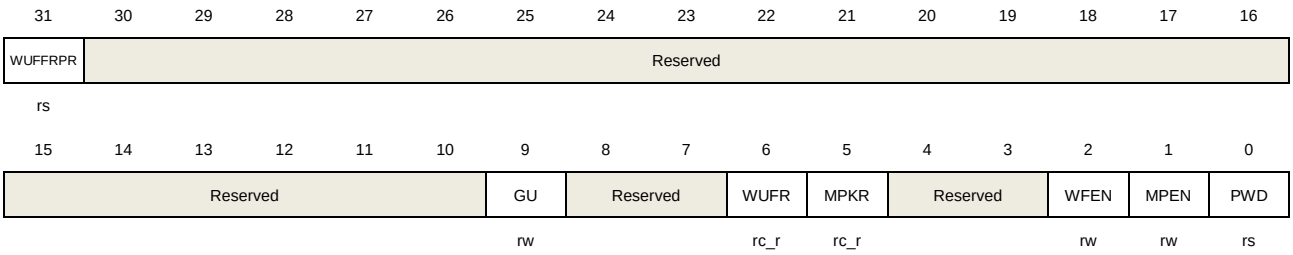


27.4.11. MAC wakeup management register (ENET_MAC_WUM)

Address offset: 0x002C

Reset value: 0x0000 0000

This register configures the request of wakeup events and monitors the wakeup events.



Bits	Fields	Descriptions
31	WUFFRPR	Wakeup frame filter register pointer reset bit This bit can reset the inner pointer of ENET_MAC_RWFF register by application set it to 1. Hardware clears it when resetting completes. 0: No effect 1: Reset the ENET_MAC_RWFF register inner pointer
30:10	Reserved	Must be kept at reset value
9	GU	Global unicast bit 0: Not all of received unicast frame is considered to be a wakeup frame

		1: Any received unicast frame passed address filtering is considered to be a wakeup frame
8:7	Reserved	Must be kept at reset value
6	WUFR	Wakeup frame received bit This bit is cleared when this register is read 0:Has not received the wake-up frame 1:The wakeup event was generated due to reception of a wakeup frame
5	MPKR	Magic packet received bit This bit is cleared when this register is read 0:Has not received the Magic Packet frame 1:The wakeup event was generated by the reception of a Magic Packet frame
4:3	Reserved	Must be kept at reset value
2	WFEN	Wakeup frame enable bit 0: Disable generating a wakeup event due to wakeup frame reception 1: Enable generating a wakeup event due to wakeup frame reception
1	MPEN	Magic Packet enable bit 0: Disable generating a wakeup event due to Magic Packet reception 1: Enable generating a wakeup event due to Magic Packet reception
0	PWD	Power down bit This bit is set by application and reset by hardware. When this bit is set, MAC drops all received frames. When power-down mode exit because of wakeup event occurred, hardware resets this bit.

27.4.12. MAC interrupt flag register (ENET_MAC_INTF)

Address offset: 0x0038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

						rc_r			r	r	r	r			

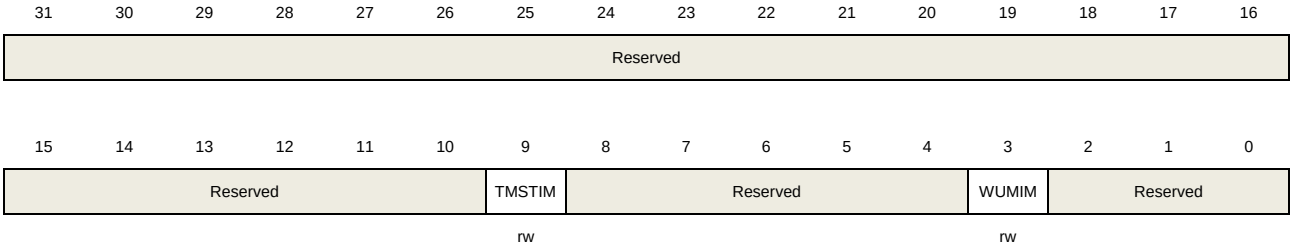
Bits	Fields	Descriptions
31:10	Reserved	Must be kept at reset value
9	TMST	Time stamp trigger status bit This bit is cleared when ENET_PTP_TSF register is read

		0: The system time value is less than the value specified in the target time registers 1: The system time value equals or exceeds the value specified in the target time registers
8:7	Reserved	Must be kept at reset value
6	MSCT	MSC transmit status bit 0: All the bits in register ENET_MSC_TINTF are cleared 1: An interrupt is generated in the ENET_MSC_TINTF register
5	MSCR	MSC receive status bit 0: All the bits in register ENET_MSC_RINTF are cleared 1: An interrupt is generated in the ENET_MSC_RINTF register
4	MSC	MSC status bit This bit is logic ORed from MSCT and MSCR bit. 0: Both MSCT and MSCR bits in this register are low 1: Any of bit 6 (MSCT) or bit 5 (MSCR) is set high
3	WUM	WUM status bit This bit is logic ORed from WUFR and MPKR bit in ENET_MAC_WUM register. 0: Wakeup frame or Magic Packet frame is not received 1: A Magic packet or remote wakeup frame is received in power down Mode
2:0	Reserved	Must be kept at reset value

27.4.13. MAC interrupt mask register (ENET_MAC_INTMSK)

Address offset: 0x003C

Reset value: 0x0000 0000



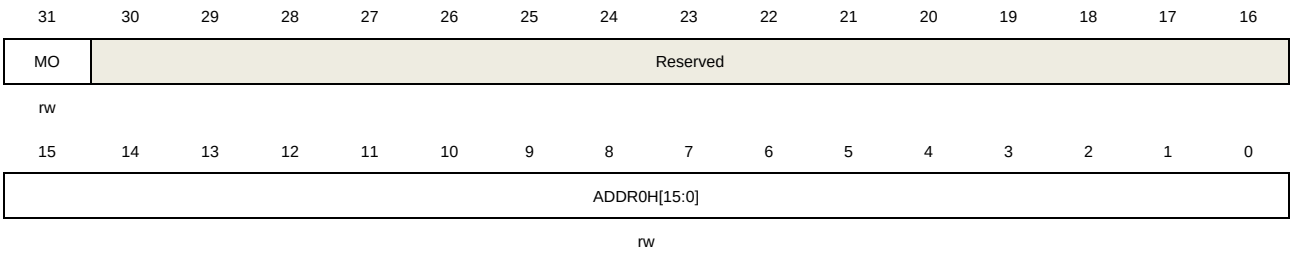
Bits	Fields	Descriptions
31:10	Reserved	Must be kept at reset value
9	TMSTIM	Timestamp trigger interrupt mask bit 0:Unmask the timestamp interrupt generation 1:Mask the timestamp interrupt generation
8:4	Reserved	Must be kept at reset value
3	WUMIM	WUM interrupt mask bit

		0: Unmask the interrupt generation due to the WUM bit in ENET_MAC_INTF register 1: Mask the interrupt generation due to the WUM bit in ENET_MAC_INTF register
2:0	Reserved	Must be kept at reset value

27.4.14. MAC address 0 high register (ENET_MAC_ADDR0H)

Address offset: 0x0040

Reset value: 0x8000 FFFF

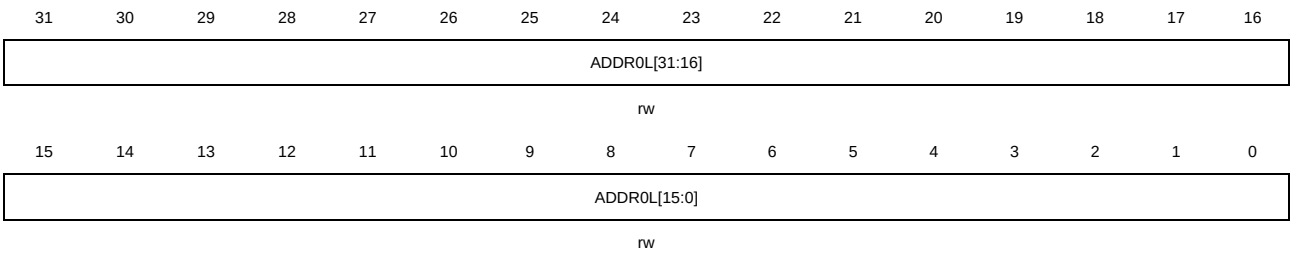


Bits	Fields	Descriptions
31	MO	Always read 1 and must be kept
30:16	Reserved	Must be kept at reset value
15:0	ADDR0H[15:0]	MAC address0 high16-bit These bits contain the high 16-bit (bit 47 to 32) of the 6-byte MAC address0. These bits are used for address filtering in frame reception and address inserting in pause frame transmitting during transmit flow control.

27.4.15. MAC address 0 low register (ENET_MAC_ADDR0L)

Address offset: 0x0044

Reset value: 0xFFFF FFFF



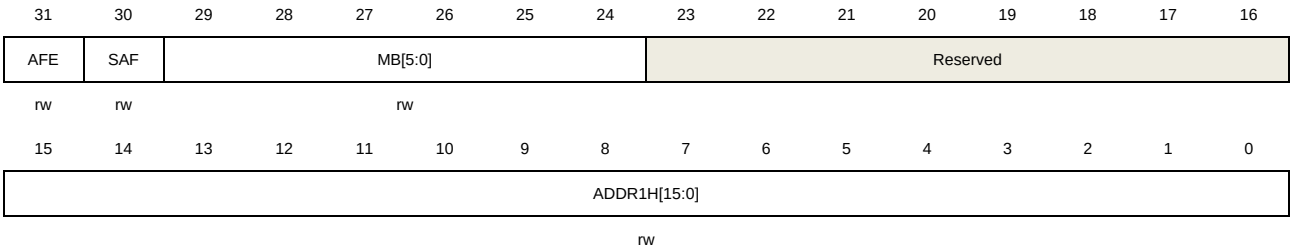
Bits	Fields	Descriptions
31:0	ADDR0L[31:0]	MAC addresss0 low 32-bit

These bits contain the low 32-bit (bit 31 to 0) of the 6-byte MAC address0. These bits are used for address filtering in frame reception and address inserting in pause frame transmitting during transmit flow control.

27.4.16. MAC address 1 high register (ENET_MAC_ADDR1H)

Address offset: 0x0048

Reset value: 0x0000 FFFF

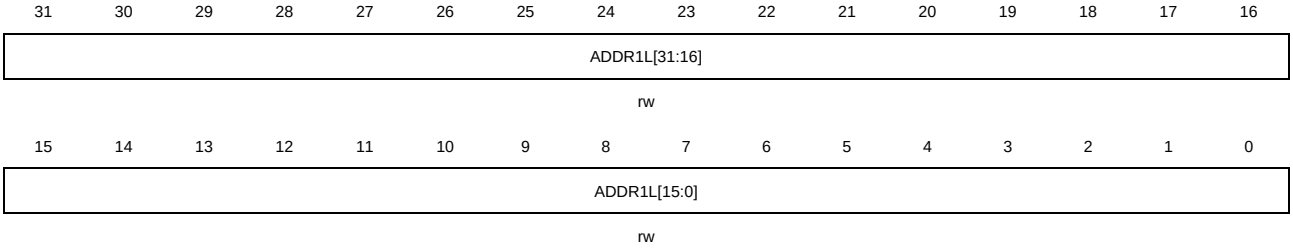


Bits	Fields	Descriptions
31	AFE	Address filter enable bit 0: The address filter ignores the MAC address1 for filtering 1: The address filter uses the MAC address1 for perfect filtering
30	SAF	Source address filter bit 0: The MAC address1[47:0] is used to comparing with the DA field of the received frame 1: The MAC address1[47:0] is used to comparing with the SA field of the received frame
29:24	MB[5:0]	Mask byte bits When they are set high, the MAC does not compare the corresponding byte of received DA/SA with the contents of the MAC address1 registers. Each bit controls one byte mask as follows: MB[5]: ENET_MAC_ADDR1H [15:8] MB[4]: ENET_MAC_ADDR1H [7:0] MB[3]: ENET_MAC_ADDR1L [31:24] MB[2]: ENET_MAC_ADDR1L[23:16] MB[1]: ENET_MAC_ADDR1L[15:8] MB[0]: ENET_MAC_ADDR1L [7:0]
23:16	Reserved	Must be kept at reset value
15:0	ADDR1H[15:0]	MAC address1 high [47:32] bits This field contains the high 16-bit (bit 47 to 32) of the 6-byte MAC address1

27.4.17. MAC address 1 low register (ENET_MAC_ADDR1L)

Address offset: 0x004C

Reset value: 0xFFFF FFFF

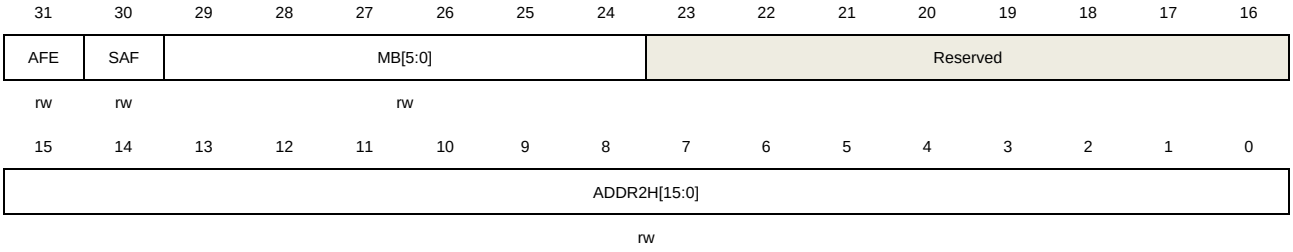


Bits	Fields	Descriptions
31:0	ADDR1L[31:0]	MAC address1 low 32-bit This field contains the low 32-bit of the 6-byte MAC address1

27.4.18. MAC address 2 high register (ENET_MAC_ADDR2H)

Address offset: 0x0050

Reset value: 0x0000 FFFF



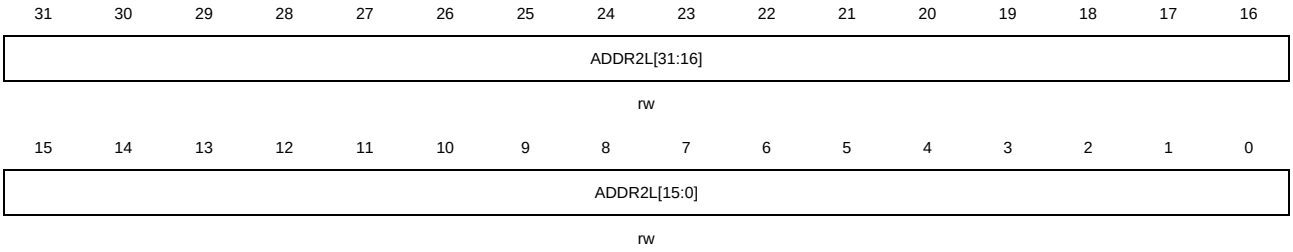
Bits	Fields	Descriptions
31	AFE	Address filter enable bit 0:The address filter ignores the MAC address2 for filtering 1:The address filter uses the MAC address2 for perfect filtering
30	SAF	Source address filter bit 0:The MAC address2[47:0] is used to comparing with the DA fields of the received frame 1:The MAC address2[47:0] is used to comparing with the SA fields of the received frame
29:24	MB[5:0]	Mask byte bits When they are set high, the MAC does not compare the corresponding byte of received DA/SA with the contents of the MAC address2 registers. Each bit controls one byte mask as follows: MB[5]: ENET_MAC_ADDR2H [15:8] MB[4]: ENET_MAC_ADDR2H [7:0]

		MB[3]: ENET_MAC_ADDR2L [31:24] MB[2]: ENET_MAC_ADDR2L[23:16] MB[1]: ENET_MAC_ADDR2L[15:8] MB[0]: ENET_MAC_ADDR2L [7:0]
23:16	Reserved	Must be kept at reset value
15:0	ADDR2H[15:0]	MAC address2 high 16-bit This field contains the high 16-bit (bit 47 to 32) of the 6-byte MAC address2

27.4.19. MAC address 2 low register (ENET_MAC_ADDR2L)

Address offset: 0x0054

Reset value: 0xFFFF FFFF

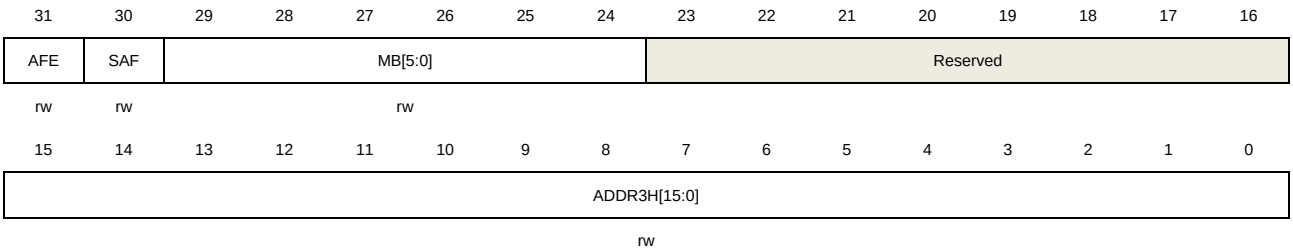


Bits	Fields	Descriptions
31:0	ADDR2L[31:0]	MAC address2 low 32-bit This field contains the low 32-bit of the 6-byte MAC address2

27.4.20. MAC address 3 high register (ENET_MAC_ADDR3H)

Address offset: 0x0058

Reset value: 0x0000 FFFF



Bits	Fields	Descriptions
31	AFE	Address filter enable bit 0:The address filter ignores the MAC address3 for filtering 1:The address filter use the MAC address3 for perfect filtering

30	SAF	Source address filter bit 0:The MAC address3[47:0] is used to comparing with the DA fields of the received frame 1:The MAC address3[47:0] is used to comparing with the SA fields of the received frame
29:24	MB[5:0]	Mask byte bits When they are set high, the MAC does not compare the corresponding byte of received DA/SA with the contents of the MAC address3 registers. Each bit controls one byte mask as follows: MB[5]: ENET_MAC_ADDR3H [15:8] MB[4]: ENET_MAC_ADDR3H [7:0] MB[3]: ENET_MAC_ADDR3L [31:24] MB[2]: ENET_MAC_ADDR3L[23:16] MB[1]: ENET_MAC_ADDR3L[15:8] MB[0]: ENET_MAC_ADDR3L [7:0]
23:16	Reserved	Must be kept at reset value
15:0	ADDR3H[15:0]	MAC address3 high 16-bit This field contains the high 16-bit (bit 47 to 32) of the 6-byte MAC address3

27.4.21. MAC address 3 low register (ENET_MAC_ADDR3L)

Address offset: 0x005C

Reset value: 0xFFFF FFFF

Bits	Fields	Descriptions
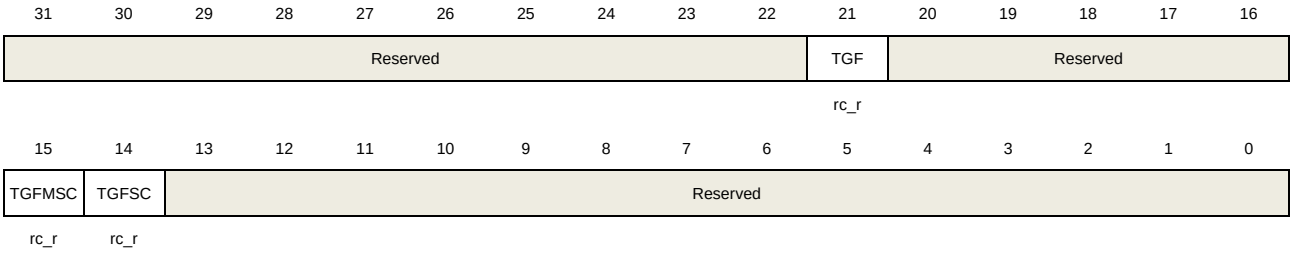
31:18	Reserved	Must be kept at reset value
17	RGUF	Received good unicast frames bit 0: Good unicast frame received counter is less than half of the maximum value 1: Good unicast frame received counter reaches half of the maximum value

16：7	Reserved	Must be kept at reset value
6	RFAE	Received frames alignment error bit 0: Alignment error frame received counter is less than half of the maximum value 1: Alignment error frame received counter reaches half of the maximum value
5	RFCE	Received frames CRC error bit 0: CRC error frame received counter is less than half of the maximum value 1: CRC error frame received counter reaches half of the maximum value
4:0	Reserved	Must be kept at reset value

27.4.24. MSC transmit interrupt flag register (ENET_MSC_TINTF)

Address offset: 0x0108

Reset value: 0x0000 0000



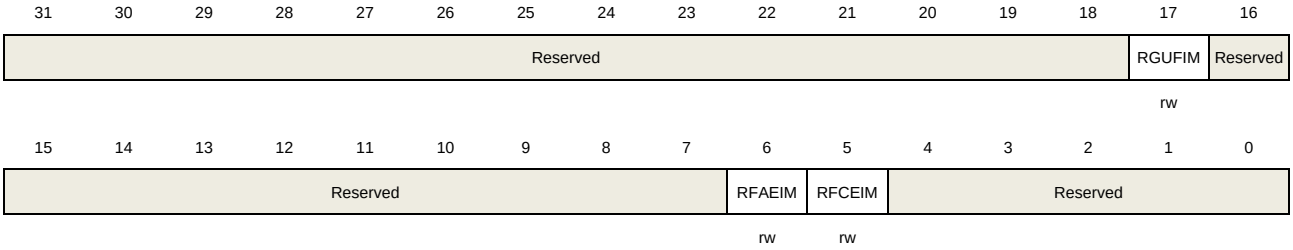
Bits	Fields	Descriptions
31:22	Reserved	Must be kept at reset value
21	TGF	Transmitted good frames bit 0: Good frame transmitted counter is less than half of the maximum value 1: Good frame transmitted counter reaches half of the maximum value
20:16	Reserved	Must be kept at reset value
15	TGFMSC	Transmitted good frames more single collision bit 0: Good frame after more than a single collision transmitted counter is less than half of the maximum value 1:Good frame after more than a single collision transmitted counter reaches half of the maximum value
14	TGFSC	Transmitted good frames single collision bit 0: Good frame after a single collision transmitted counter is less than half of the maximum value 1: Good frame after a single collision transmitted counter reaches half of the maximum value
13:0	Reserved	Must be kept at reset value

27.4.25. MSC receive interrupt mask register (ENET_MSC_RINTMSK)

Address offset: 0x010C

Reset value: 0x0000 0000

The Ethernet MSC receive interrupt mask register maintains the masks for interrupts generated when receive statistic counters reach half their maximum value



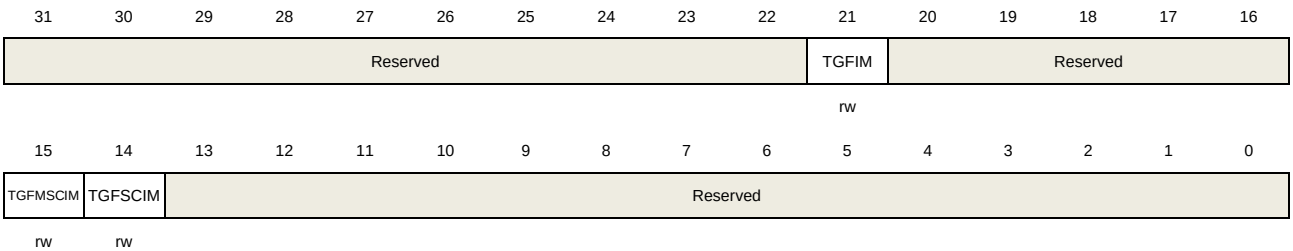
Bits	Fields	Descriptions
31:18	Reserved	Must be kept at reset value
17	RGUFIM	Received good unicast frames interrupt mask bit 0: Unmask the interrupt when the RGUF bit is set 1: Mask the interrupt when RGUF bit is set
16:7	Reserved	Must be kept at reset value
6	RFAEIM	Received frames alignment error interrupt mask bit 0: Unmask the interrupt when the RFAE bit is set 1: Mask the interrupt when the RFAE bit is set
5	RFCEIM	Received frame CRC error interrupt mask bit 0: Unmask the interrupt when RFCE bit is set 1: Mask the interrupt when the RFCE bit is set
4:0	Reserved	Must be kept at reset value

27.4.26. MSC transmit interrupt mask register (ENET_MSC_TINTMSK)

Address offset: 0x0110

Reset value: 0x0000 0000

The MSC transmit interrupt mask register configures the mask bits for interrupts generation



Bits	Fields	Descriptions
31:22	Reserved	Must be kept at reset value
21	TGFIM	Transmitted good frames interrupt mask bit 0: Unmask the interrupt when the TGF bit is set 1:Mask the interrupt when the TGF bit is set
20:16	Reserved	Must be kept at reset value
15	TGFMSCIM	Transmitted good frames more single collision interrupt mask bit 0: Unmask the interrupt when the TGFMSC bit is set 1: Mask the interrupt when the TGFMSC bit is set
14	TGFSCIM	Transmitted good frames single collision interrupt mask bit 0: Unmask the interrupt when the TFGSC bit is set 1: Mask the interrupt when the TFGSC bit is set
13:0	Reserved	Must be kept at reset value

27.4.27. MSC transmitted good frames after a single collision counter register (ENET_MSC_SCCNT)

Address offset: 0x014C
Reset value: 0x0000 0000

This register counts the number of successfully transmitted frames after a single collision in Half-duplex mode.

Bits	Fields	Descriptions
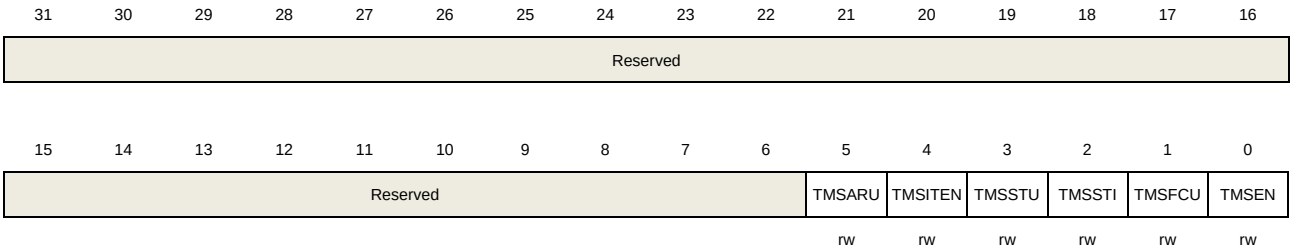
31:0	RGUF[31:0]	Received good unicast frames counter bits These bits count the number of good unicast frames received.

27.4.33. PTP time stamp control register (ENET_PTP_TSCTL)

Address offset: 0x0700

Reset value: 0x0000 0000

This register configures the generation and updating for timestamp.



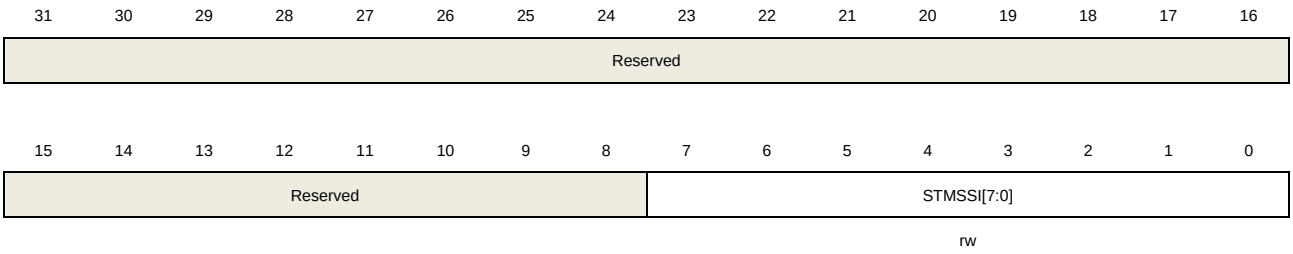
Bits	Fields	Descriptions
31:6	Reserved	Must be kept at reset value
5	TMSARU	Time stamp addend register update bit This bit is cleared when the update is completed. This register bit must be read as zero before application set it. 0: The timestamp addend register's contents are not updated to the PTP block for fine correction 1: The timestamp addend register's contents are updated to the PTP block for fine correction
4	TMSITEN	Timestamp interrupt trigger enable bit 0: Disable timestamp interrupt 1: A timestamp interrupt is generated when the system time becomes greater than the value written in target time register. **Note:** When the timestamp trigger interrupt generated, this bit is cleared
3	TMSSTU	Timestamp system time update bit Both the TMSSTU and TMSSTI bits must be read as zero before application set this bit 0: The system time is maintained without any change 1: The system time is updated (added to or subtracted from) with the value specified in the timestamp update (high and low) registers. It is cleared by hardware when the update finished.
2	TMSSTI	Timestamp system time initialize bit

		This bit must be read as zero before application set it. 0: The system time is maintained without any change 1: Initializing the system time with the value in timestamp update (high and low) registers. It is cleared by hardware when the initialization finished.
1	TMSFCU	Timestamp fine or coarse update bit 0:The system timestamp uses the coarse method for updating 1:The system timestamp uses the fine method for updating
0	TMSEN	Timestamp enable bit 0: Disable timestamp function 1: Enable timestamp function for transmit and receive frames **Note:** After setting this to 1, application must initialize the system time.

27.4.34. PTP subsecond increment register (ENET_PTP_SSINC)

Address offset: 0x0704
Reset value: 0x0000 0000

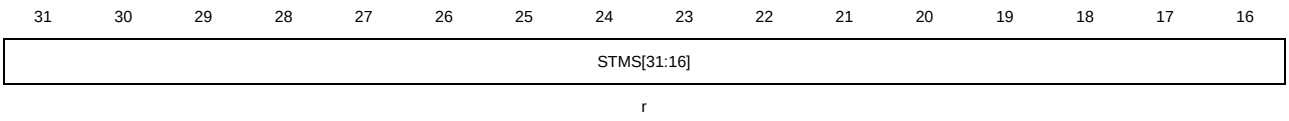
This register configures the 8-bit value for the incrementing subsecond register. In coarse mode, this value is added to the system time every HCLK clock cycle. In fine mode, this value is added to the system time when the accumulator reaches overflow.



Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value
7:0	STMSSI[7:0]	System time subsecond increment bits In every update operation, these bits are added to the subsecond value of system time.

27.4.35. PTP time stamp high register (ENET_PTP_TSH)

Address offset: 0x0708
Reset value: 0x0000 0000



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
STMS[15:0]															
r															

Bits	Fields	Descriptions
31:0	STMS[31:0]	System time second bits These bits show the current second of the system time.

27.4.36. PTP time stamp low register (ENET_PTP_TSL)

Address offset: 0x070C

Reset value: 0x0000 0000

r															

Bits	Fields	Descriptions
31	STS	System time sign bit 0: Time value is positive 1: Time value is negative
30:0	STMSS[30:0]	System time subseconds bits These bits show the current subsecond of the system time with 0.46 ns accuracy if required accuracy is 20 ns.

27.4.37. PTP time stamp update high register (ENET_PTP_TSUH)

Address offset: 0x0710

Reset value: 0x0000 0000

This register configures the high 32-bit of the time to be written to, added to, or subtracted from the system time value. The timestamp update registers (high and low) initialize or update the system time maintained by the MAC core. Application must write both of these registers before setting the TMSSTI or TMSSTU bits in the timestamp control register.

rw

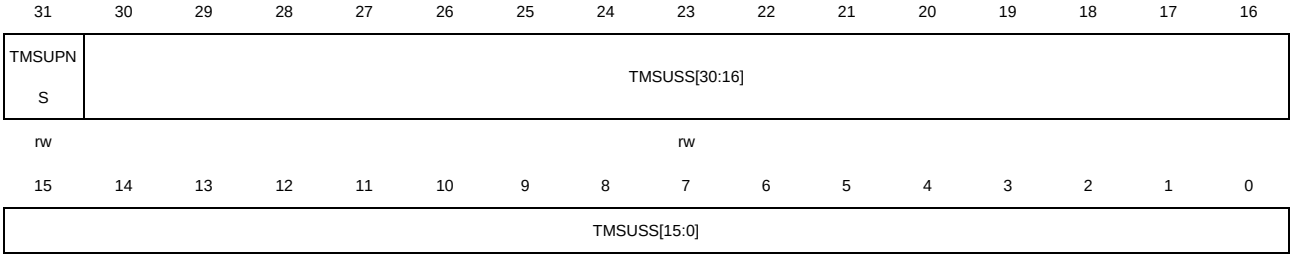
Bits	Fields	Descriptions
31:0	TMSUS[31:0]	Time stamp update second bits These bits are used for initializing or adding/subtracting to second of the system time

27.4.38. PTP time stamp update low register (ENET_PTP_TSUL)

Address offset: 0x0714

Reset value: 0x0000 0000



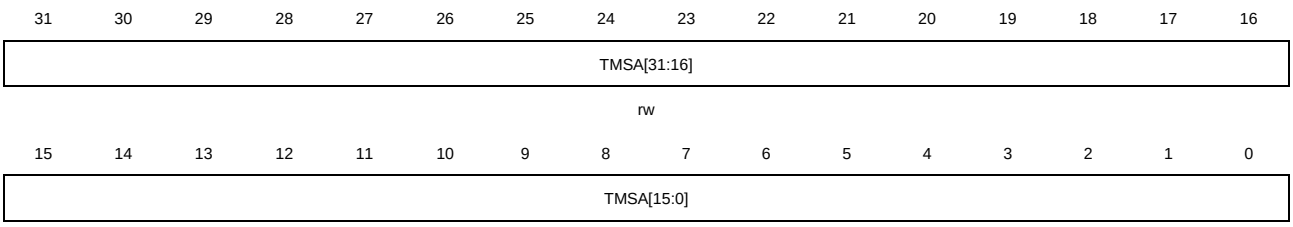
Bits	Fields	Descriptions
31	TMSUPNS	Timestamp update positive or negative sign bit When TMSSTI is set, this bit must be 0. 0: Timestamp update value is added to system time 1: Timestamp update value is subtracted from system time
30:0	TMSUSS[30:0]	Timestamp update subsecond bits These bits are used for initializing or adding/subtracting to subsecond of the system time

27.4.39. PTP time stamp addend register (ENET_PTP_TSADDEND)

Address offset: 0x0718

Reset value: 0x0000 0000

This register value is used only in fine update mode for adjusting the clock frequency. This register value is added to a 32-bit accumulator in every clock cycle and the system time updates when the accumulator reaches overflow.



rw

Bits	Fields	Descriptions
31:0	TMSA[31:0]	Time stamp addend bits These registers contain a 32-bit time value which is added to the accumulator register to achieve time synchronization

27.4.40. PTP expected time high register (ENET_PTP_ETH)

Address offset: 0x071C

Reset value: 0x0000 0000

31:0	ETSL[31:0]	Expected time low bits These bits store the expected target nanosecond time (signed).

27.4.42. DMA bus control register (ENET_DMA_BCTL)

Address offset: 0x1000

Reset value: 0x0000 2101

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved						AA	FPBL	UIP	RXDP[5:0]						FB
						rw	rw	rw	rw						rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTPR[1:0]		PGBL[5:0]						Reserved	DPSL[4:0]					DAB	SWR
rw		rw							rw					rw	rs

Bits	Fields	Descriptions
31:26	Reserved	Must be kept at reset value
25	AA	Address-aligned bit 0: Disable address-aligned 1: Enabled address-aligned. If the FB=1, all AHB interface address is aligned to the start address LS bits (bit 1 to 0). If the FB=0, the AHB interface first access address (accessing the data buffer's start address) is not aligned, but subsequent burst access addresses are aligned to the address
24	FPBL	Four times PGBL mode bit 0: The PGBL value programmed (bits [22:17] and bits [13:8]) for the DMA data number of beats to be transferred 1: Multiple the PGBL value programmed (bits [22:17] and bits [13:8]) four times for the DMA data number of beats to be transferred
23	UIP	Use independent PGBL bit 0: The PGBL value in bits [13:8] is applicable for both TxDMA and RxDMA engines 1: The RxDMA uses the RXDP[5:0] bits as burst length while the PGBL[5:0] is used by TxDMA
22:17	RXDP[5:0]	RxDMA PGBL bits If UIP=0, these bits are not valid. Only when UIP=1, these bits is configured for the maximum number of beats to be transferred in one RxDMA transaction. 0x01: max beat number is 1 0x02: max beat number is 2 0x04: max beat number is 4 0x08: max beat number is 8 0x10: max beat number is 16 0x20: max beat number is 32 Other: Reserved
16	FB	Fixed burst bit 0: The AHB can use SINGLE and INCR burst transfer operations 1: The AHB can only use SINGLE, INCR4, INCR8 or INCR16 during start of normal burst transfers **Note:** MB and FB should be and must be only one of bit is set.
15:14	RTPR[1:0]	RxDMA and TxDMA transfer priority ratio bits

		These bits indicate the access ratio between RxDMA and TxDMA. 0x0: RxDMA : TxDMA = 1:1 0x1: RxDMA : TxDMA = 2:1 0x2: RxDMA : TxDMA = 3:1 0x3: RxDMA : TxDMA = 4:1 **Note:** This bit is valid only when the arbitration mode is Round-robin (DAB=0)
13:8	PGBL[5:0]	Programmable burst length bits These bits indicate the maximum number of beats to be transferred in one DMA transaction. When UIP=1, the PGBL value is only used for TxDMA. When UIP=0, the PGBL value is used for both TxDMA and RxDMA. 0x01: max beat number is 1 0x02: max beat number is 2 0x04: max beat number is 4 0x08: max beat number is 8 0x10: max beat number is 16 0x20: max beat number is 32 Other: Reserved
7	Reserved	Must be kept at reset value
6:2	DPSL[4:0]	Descriptor skip length bit These bits are valid only between two ring mode descriptors. They define the number of words (32-bit) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DPSL value equals zero, the descriptor table is taken as contiguous by the DMA, in ring mode
1	DAB	DMA arbitration bit This bit indicates the arbitration mode between RxDMA and TxDMA. 0: Round-robin mode and DMA access priority is given in RTPR 1: Fixed mode. RxDMA has higher priority than TxDMA
0	SWR	Software reset bit This bit can reset all core internal registers located in CLK_TX and CLK_RX. It is cleared by hardware when the reset operation is complete in all clock domains. **Note:** Application must make sure this bit is 0 before writing any MAC core registers. 0: Core and inner register are not in reset state 1: Reset all core internal registers

27.4.43. DMA transmit poll enable register (ENET_DMA_TPEN)

Address offset: 0x1004
Reset value: 0x0000 0000

This register is used by the application to make the TxDMA controller poll the transmit descriptor table. The TxDMA controller can go into suspend state because of an underflow

error in a transmitted frame or the descriptor unavailable (DAV=0). Application can write any value into this register for attempting to re-fetch the current descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw_wt															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TPE[15:0]															
rw_wt															

Bits	Fields	Descriptions
31:0	TPE[31:0]	Transmit poll enable bits Writing to this register with any value makes DMA read the current descriptor address which is indicated in ENET_DMA_CTDADDR register. If the fetched current descriptor is available (DAV=1), DMA exits suspend state and resumes working. If the fetched current descriptor is unavailable (DAV=0), the DMA returns to suspend state again and the TBU bit in ENET_DMA_STAT register will be set.

27.4.44. DMA receive poll enable register (ENET_DMA_RPEN)

Address offset: 0x1008

Reset value: 0x0000 0000

This register is used by the application to make the RxDMA controller poll the receive descriptor table. Writing to this register makes the RxDMA controller exit suspend state.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw_wt															

Bits	Fields	Descriptions
31:0	RPE[31:0]	Receive poll enable bits Writing to this register with any value makes DMA read the current descriptor address which is indicated in ENET_DMA_CRDADDR register. If the fetched current descriptor is available (DAV=1), DMA exits suspend state and resumes working. If the fetched current descriptor is unavailable (DAV=0), the DMA returns to suspend state again and the RBU bit in ENET_DMA_STAT register will be set.

27.4.45. DMA receive descriptor table address register (ENET_DMA_RDTADDR)

Address offset: 0x100C

Reset value: 0x0000 0000

This register points to the start of the receive descriptor table. The descriptor table is located in the physical memory space and must be word-aligned. This register can only be written when RxDMA controller is in stop state. Before starting RxDMA reception process, this register must be configured correctly.

Bits	Fields	Descriptions
31:0	SRT[31:0]	Start address of receive table bits These bits indicate the start address of the receive descriptor table. SRT[1:0] are internally taken as zero so SRT[1:0] are read only.

27.4.46. DMA transmit descriptor table address register (ENET_DMA_TDTADDR)

Address offset: 0x1010
Reset value: 0x0000 0000

This register points to the start of the transmit descriptor table. The descriptor table is located in the physical memory space and must be word-aligned. This register can only be written when TxDMA controller is in stop state. Before starting TxDMA transmission process, this register must be configured correctly.

Bits	Fields	Descriptions
31:0	STT[31:0]	Start address of transmit table bits These bits indicate the start address of the transmit descriptor table. STT[1:0] are internally taken as zero so STT[1:0] are read only.

27.4.47. DMA status register (ENET_DMA_STAT)

Address offset: 0x1014

Reset value: 0x0000 0000

This register contains all the status bits that the DMA controller recorded. Writing 1 to meaningful bits in this register clears them but writing 0 has no effect. Each bit (bits [16:0]) can be masked by masking the corresponding bit in the ENET_DMA_INTEN register.

Bits	Fields	Descriptions
31:30	Reserved	Must be kept at reset value
29	TST	Timestamp trigger status bit This bit indicates a timestamp event occurred. It is cleared by application through clearing TMST bit. If the corresponding interrupt mask bit is reset, an interrupt is generated. 0: Timestamp event has not occurred 1: Timestamp event has occurred
28	WUM	WUM status bit This bit indicates a WUM event occurred. It is cleared when both two source event status bits are cleared. If the corresponding interrupt mask bit is reset, an interrupt is generated. 0: WUM event has not occurred 1: WUM event has occurred
27	MSC	MSC status bit This bit indicates a MSC event occurred. It is cleared when all of event sources are cleared. If the corresponding interrupt mask bit is reset, an interrupt is generated. 0: MSC event has not occurred 1: MSC event has occurred
26	Reserved	Must be kept at reset value
25:23	EB[2:0]	Error bits status bit When FBE=1, these bits decode the type of error that caused a bus response error on AHB bus. EB[0] 1: Error during data transfer by TxDMA 0: Error during data transfer by RxDMA EB[1] 1: Error during read transfer 0: Error during write transfer EB[2] 1: Error during descriptor access

		0: Error during data buffer access
22:20	TP[2:0]	Transmit process state bit These bits decode the TxDMA state. 0x0: Stopped; Reset or Stop Transmit Command issued 0x1: Running; Fetching transmit transfer descriptor 0x2: Running; Waiting for status 0x3: Running; Reading Data from host memory buffer and queuing it to transmit buffer (TxFIFO) 0x4, 0x5: Reserved 0x6: Suspended; Transmit descriptor unavailable or transmit buffer underflow 0x7: Running; Closing transmit descriptor
19:17	RP[2:0]	Receive process state bit These bits decode the RxDMA state. 0x0: Stopped: Reset or Stop Receive Command issued 0x1: Running: Fetching receive transfer descriptor 0x2: Reserved 0x3: Running: Waiting for receive packet 0x4: Suspended: Receive descriptor unavailable 0x5: Running: Closing receive descriptor 0x6: Reserved 0x7: Running: Transferring the receive packet data from receive buffer to host memory
16	NI	Normal interrupt summary The NI bit is logical ORed of the following if the corresponding interrupt bit is enabled in the ENET_DMA_INTEN register: TS (ENET_DMA_STAT [0]): Transmit interrupt TBU (ENET_DMA_STAT [2]): Transmit buffer unavailable RS (ENET_DMA_STAT [6]): Receive interrupt ER (ENET_DMA_STAT [14]): Early receive interrupt **Note:** Each time when this bit is set, application must cleared its source bit by writing 1 to that bit.
15	AI	Abnormal interrupt summary bit The AI bit is logical ORed of the following if the corresponding interrupt bit is enabled in the ENET_DMA_INTEN register: TPS (ENET_DMA_STAT [1]):Transmit process stopped TJT (ENET_DMA_STAT [3]):Transmit jabber timeout RO (ENET_DMA_STAT [4]): Receive FIFO overflow TU (ENET_DMA_STAT [5]): Transmit underflow RBU (ENET_DMA_STAT [7]): Receive buffer unavailable RPS (ENET_DMA_STAT [8]): Receive process stopped RWT (ENET_DMA_STAT [9]): Receive watchdog timeout ET (ENET_DMA_STAT [10]): Early transmit interrupt

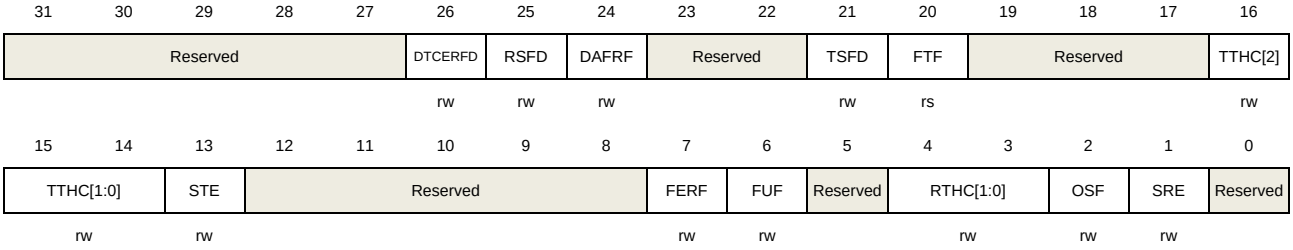
		FBE (ENET_DMA_STAT [13]): Fatal bus error **Note:** Each time when this bit is set, application must cleared its source bit by writing 1 to that bit.
14	ER	Early receive status bit This bit is automatically cleared when the ENET_DMA_STAT [6] is set. 0: The first buffer has not been filled 1: The first buffer has filled with received frame
13	FBE	Fatal bus error status bit This bit indicates a response error on AHB interface is occurred and the error type can be decoded by EB[2:0] bits. 0: Bus error has not occurred 1: A bus error occurred and the corresponding DMA stops all operations
12:11	Reserved	Must be kept at reset value
10	ET	Early transmit status bit 0: The frame to be transmitted has not fully transferred into the TxFIFO 1: The frame to be transmitted has fully transferred into the TxFIFO
9	RWT	Receive watchdog timeout status bit 0: A frame with a length less than 2048 bytes is received 1: A frame with a length greater than 2048 bytes is received
8	RPS	Receive process stopped status bit 0: The receive process is not in stop state 1: The receive process is in stop state
7	RBU	Receive buffer unavailable status bit 0: The DAV bit in fetched next receive descriptor is set 1: The DAV bit in fetched next receive descriptor is reset and RxDMA enters suspend state.
6	RS	Receive status bit 0: Frame reception has not completed 1: Frame reception has completed
5	TU	Transmit underflow status bit 0: Underflow error has not occurred during frame transmission 1: The TxFIFO encountered an underflow error during frame transmission and entered suspend state
4	RO	Receive overflow status bit 0: Receive overflow error has not occurred during frame reception 1: The RxFIFO encountered an overflow error during frame reception. If a part of frame data has transferred to the memory, the overflow status in RDES0[11] is also set

3	TJT	Transmit jabber timeout status bit 0: Transmit jabber timeout has not occurred during frame transmission 1: The transmit jabber timer expired. The TxDMA controller cancels the current transmission and enters stop state. This also causes JT bit in TDES0 set.
2	TBU	Transmit buffer unavailable status bit 0: The DAV bit in fetched next transmit descriptor is set 1: The DAV bit in fetched next transmit descriptor is reset and TxDMA enters suspend state.
1	TPS	Transmit process stopped status bit 0: The transmission is not in stop state 1: The transmission is in stop state
0	TS	Transmit status bit This bit can only be set when both LSG and INTC are set in TDES0. 0: Current frame transmission is not finished 1: Current frame transmission is finished.

27.4.48. DMA control register (ENET_DMA_CTL)

Address offset: 0x1018
Reset value: 0x0000 0000

This register configures both the transmitting and receiving operation modes and commands. This register should be written at last during the process of DMA initialization.



Bits	Fields	Descriptions
31:27	Reserved	Must be kept at reset value
26	DTCERFD	Dropping of TCP/IP checksum error frames disable bit 0: All error frames will be dropped when FERF=0 1: The received frame with only payload error but no other errors will not be dropped.
25	RSFD	Receive Store-and-Forward bit 0: The RxFIFO operates in Cut-Through mode. The forwarding threshold depends on the RTHC bits 1: The RxFIFO operates in Store-and-Forward mode. The RTHC bits are ignored and the frame forwarding starts after the whole frame has pushed into RxFIFO.

24	DAFRF	Disable flushing of received frames bit 0: The RxDMA flushes all frames because of unavailable receive descriptor 1: The RxDMA does not flush any frames even though receive descriptor is unavailable
23:22	Reserved	Must be kept at reset value
21	TSFD	Transmit Store-and-Forward bit 0: The TxFIFO operates in Cut-Through mode. The TTHC bits in ENET_DMA_CTL register defines the start popping time from TxFIFO 1: The TxFIFO operates in Store-and-Forward mode. Transmission on interface starts after the full frame has been pushed into the TxFIFO. The TTHC bits are ignored in this mode. **Note:** This bit can be changed when transmission is in stop state
20	FTF	Flush transmit FIFO bit This bit can be set by application to reset TxFIFO inner control register and logic. If set, all data in TxFIFO are flushed. It is cleared by hardware after the flushing operation is finish. **Note:** Before this bit is reset, this register (ENET_DMA_CTL) must not be written.
19:17	Reserved	Must be kept at reset value
16:14	TTHC[2:0]	Transmit threshold control bit These bits control the start transmitting byte threshold of the TxFIFO. When TSFD=1, these bits are ignored. 0x0: 64 0x1: 128 0x2: 192 0x3: 256 0x4: 40 0x5: 32 0x6: 24 0x7: 16
13	STE	Start/stop transmission enable bit 0: The TxDMA controller will enter stop state after transmitting complete if the current frame is being transmitted. After complete transmitting, the next descriptor address will become current descriptor address for the address pointer. If the TxDMA controller is in suspend state, reset this bit make the controller entering stop state. 1: The TxDMA controller will enter running state. TxDMA controller fetches current descriptor address for frame transmitting. Transmit descriptor's fetching can either from base address in ENET_DMA_TDTADDR register or from the pointer position when transmission was stopped previously. If the DAV bit of current descriptor is reset, TxDMA controller enters suspend state and the TBU bit will be set. This bit

		should be set after all other DMA registers have been configured otherwise the action of TxDMA is unpredictable.
12:8	Reserved	Must be kept at reset value
7	FERF	Forward error frames bit 0: When RxFIFO is in Cut-Through mode (RSFD=0), if frame error (CRC error, collision error, checksum error, watchdog timeout, overflow error) is detected before popping RxFIFO data to memory, RxFIFO drops this error frame. But if frame error is detected after popping RxFIFO data to memory, RxFIFO will not drop this frame data. When RxFIFO is in Store-and-Forward mode, once frame error is detected during reception the RxFIFO drops this frame. 1: All frame received with error except runt error are forwarded to memory
6	FUF	Forward undersized good frames bit 0: The RxFIFO drops all frames whose length is less than 64 bytes. However, if this frame has already started forwarding (may due to lower value of receive threshold in Cut-Through mode), the whole frame will be forwarded. 1: The RxFIFO forwards received frame whose frame length is less than 64 bytes but without any other error.
5	Reserved	Must be kept at reset value
4:3	RTHC[1:0]	Receive threshold control bit These bits control the threshold bytes of the RxFIFO. **Note:** These bits are valid only when the RSFD=0 and are ignored when the RSFD=1. 0x0: 64 0x1: 32 0x2: 96 0x3: 128
2	OSF	Operate on second frame bit 0: The TxDMA controller process the second transmit frame after the status of the first frame is written back to descriptor 1: The TxDMA controller process the second transmit frame after pushed all first frame data into TxFIFO but before the status of the first frame is written back to descriptor
1	SRE	Start/stop receive enable bit 0: The RxDMA controller will enter stop state after transfer complete if current received frame is transmitting to memory by RxDMA. After transfer complete, the next descriptor address in the receive table will become the current descriptor address when restart the RxDMA controller. Only RxDMA controller is in running state or suspend state, this bit can be reset by application. 1: The RxDMA controller will enter running state. RxDMA controller fetches receive descriptor from receive descriptor table for receiving frames. The descriptor address

		can either from current address in the ENET_DMA_RDTADDR register or the address after previous frame stopped by application. If the DAV bit in fetched descriptor is reset, RxDMA controller will enter suspend state and RBU bit will be set. This bit can be set only when RxDMA controller is in stop state or suspend state. This bit should be set after all other DMA registers have been configured, otherwise the action of RxDMA is unpredictable.
0	Reserved	Must be kept at reset value

27.4.49. DMA interrupt enable register (ENET_DMA_INTEN)

Address offset: 0x101C

Reset value: 0x0000 0000

This register configures the interrupts which are reflected in ENET_DMA_STAT register.

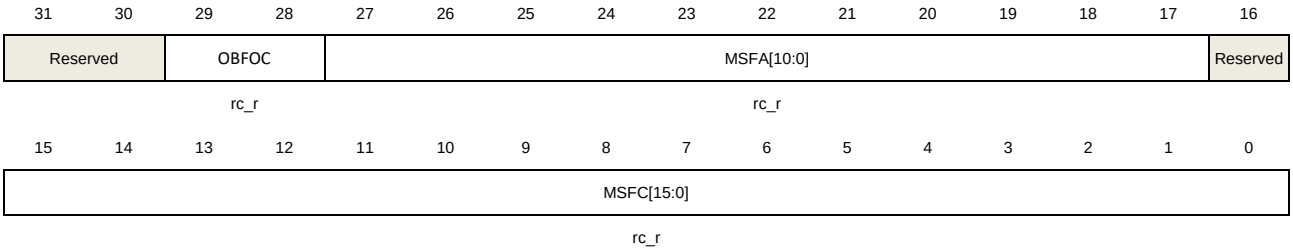
27.4.50. DMA missed frame and buffer overflow counter register (ENET_DMA_MFBOCNT)

Address offset: 0x1020
Reset value: 0x0000 0000

There are two counters designed in DMA controller for tracking the number of missed frames during receiving. The counter value can be read from this register for debug purpose.



Bits	Fields	Descriptions
31:29	Reserved	Must be kept at reset value
28	OBFOC	Overflow bit for FIFO overflow counter bit Overflow bit for FIFO overflow counter
27:17	MSFA[10:0]	Missed frames by the application bits These bits indicate the number of frames dropped by RxFIFO
16	Reserved	Must be kept at reset value
15:0	MSFC[15:0]	Missed frames by the controller bits These bits indicate the number of frames missed by the RxDMA controller because of the unavailable receive buffer. Each time the RxDMA controller flushes one frame, this counter will plus 1.

27.4.51. DMA current transmit descriptor address register (ENET_DMA_CTDADDR)

Address offset: 0x1048

Reset value: 0x0000 0000

This register points to the start descriptor address of the current transmit descriptor read by the TxDMA controller.

28. Universal serial bus full-speed interface (USBFS)

The USBFS is available on GD32F205 and GD32F207 series.

28.1. Overview

USB Full-Speed (USBFS) controller provides a USB-connection solution for portable devices. USBFS supports host and device modes, as well as OTG mode with HNP (Host Negotiation Protocol) and SRP (Session Request Protocol). USBFS contains a full-speed internal USB PHY and the external PHY chip is not contained. USBFS supports all the four types of transfer (control, bulk, Interrupt and isochronous) which defined in USB 2.0 protocol.

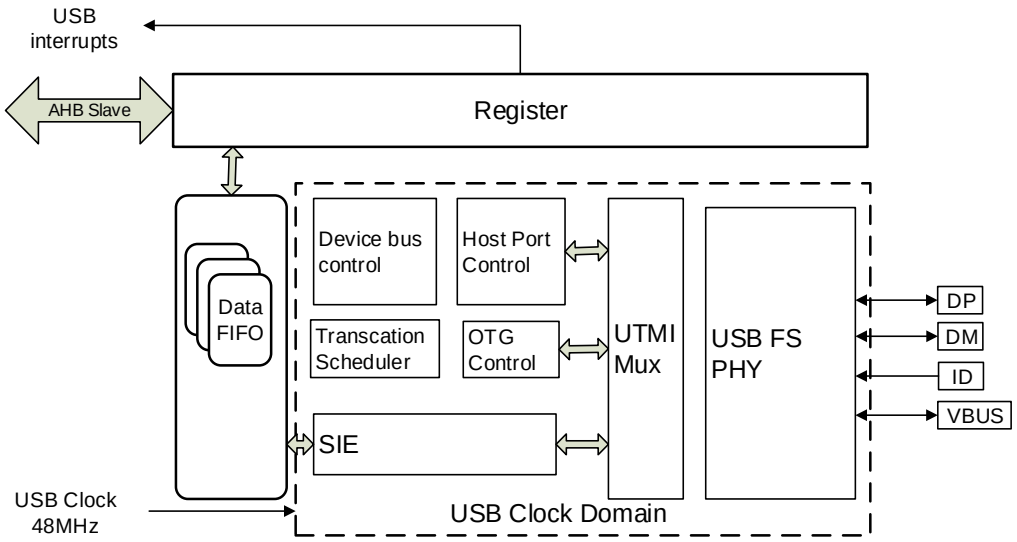
28.2. Characteristics

- Supports USB 2.0 host mode at full-speed(12Mb/s) or low-speed(1.5Mb/s)
- Supports USB 2.0 device mode at full-speed(12Mb/s)
- Supports OTG protocol with HNP (Host Negotiation Protocol) and SRP (Session Request Protocol)
- Supports all the 4 types of transfer: control, bulk, interrupt and isochronous
- Includes a USB transaction scheduler in host mode to handle USB transaction request efficiently.
- Includes a 1.25KB FIFO RAM.
- Supports 8 channels in host mode.
- Includes 2 Tx FIFOs (periodic and non-periodic) and 1 Rx FIFO (shared by all channels) in host mode.
- Includes 4 Tx FIFOs (one for each IN endpoint) and 1 Rx FIFO (shared by all OUT endpoints) in device mode.
- Supports 4 OUT and 4 IN endpoints in device mode.
- Supports remote wakeup in device mode.
- Includes a full-speed USB PHY with OTG protocol supported.
- Time intervals of SOFs is dynamic adjustable in host mode
- SOF pulse supports output to PAD.
- Supports detecting ID pin level and VBUS voltage.
- Needs external component to supply power for connected USB device in host mode or

OTG A-device mode.

28.3. Block diagram

Figure 28-1. USBFS block diagram



28.4. Signal description

Table 28-1. USBFS signal description

I/O port	Type	Description
VBUS	Input/Output	Bus power port
DM	Input/Output	Differential D-
DP	Input/Output	Differential D+
ID	Input	USB identification: Mini connector identification port

28.5. Function overview

28.5.1. USBFS clocks and working modes

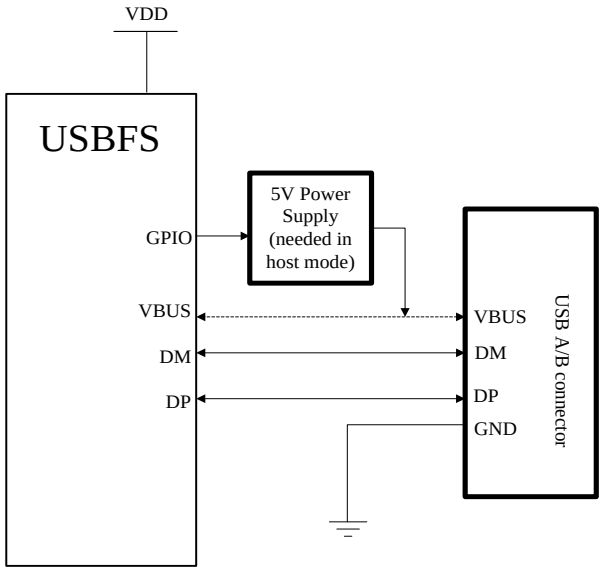
USBFS could be operated as a host, a device or a DRD (Dual-role-Device), it contains an internal full-speed PHY. The maximum speed supported by USBFS is full-speed.

The internal PHY supports Full-Speed and Low-Speed in host mode, supports full-speed in device mode, and supports OTG mode with HNP and SRP. The USB clock used by the USBFS should be 48MHz. The 48MHz USB clock is generated from internal clocks in system,

and its source and divider factors are configurable in RCU.

The pull-up and pull-down resistors have already been integrated into the internal PHY and they could be controlled by USBFS automatically according to the current mode (host, device or OTG mode) and connection status. A typical connection is shown in ***Figure 28-2. Connection with host or device mode.***

Figure 28-2. Connection with host or device mode



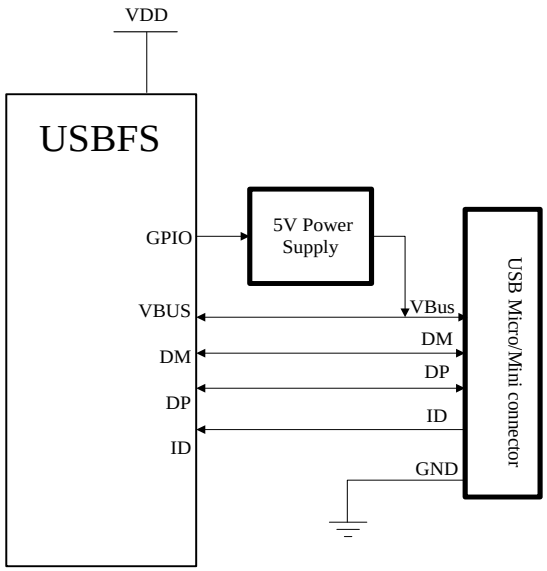
When USBFS works in host mode (FHM bit is set and FDM bit is cleared), the VBUS is 5V power supplied and detecting pin which is used for voltage detection is defined in USB protocol. The internal PHY cannot supply 5V VBUS power and only has some voltage comparers, charge and discharge circuits on VBUS line. Thus, if application needs VBUS power, an external power supply IC is needed. The VBUS connection between USBFS and the USB connector can be omitted in host mode, so USBFS doesn't detect the voltage level on VBUS pin and always assumes that the 5V power is present.

When USBFS works in device mode (FHM bit is cleared and FDM bit is set), the VBUS detection circuit is configured by VBUSIG bit in USBFS_GCCFG register. So if the device does not need to detect the voltage on VBUS pin, it could be configured by setting the VBUSIG bit, then the VBUS pin can be freed for other uses. Otherwise, the VBUS connection cannot be omitted, and USBFS continuously monitors the VBUS voltage. It will immediately switch off the pull-up resistor on DP line once that the VBUS voltage falls below the needed valid value, leading to a disconnection.

The OTG mode connection is described in the ***Figure 28-3. Connection with OTG mode***. When USBFS works in OTG mode, the FHM, FDM bits in USBFS_GUSBCS and VBUSIG bit in USBFS_GCCFG should be cleared. In this mode, the USBFS needs all the four pins: DM, DP, VBUS and ID, and needs to use several voltage comparers to monitor the voltage on these pins. USBFS also contains VBUS charge and discharge circuits to perform SRP request which is described in OTG protocol. The OTG A-Device or B-Device is decided by the level

of the ID pin. USBFS controls the pull-up or pull-down resistor during performing the HNP protocol.

Figure 28-3. Connection with OTG mode

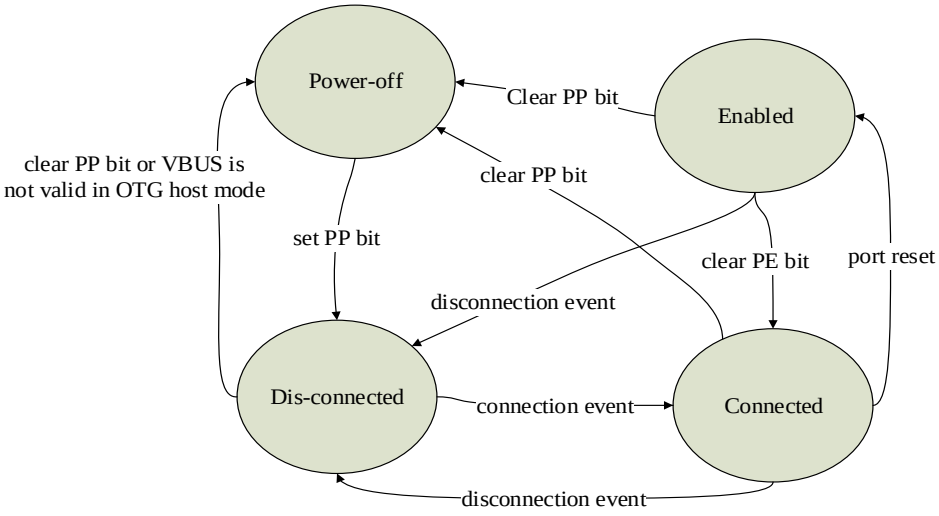


28.5.2. USB host function

USB Host Port State

Host application may control state of the USB port via USBFS_HPCS register. After system initialization, the USB port stays at power-off state. After PP bit is set by software, the internal USB PHY is powered on, and the USB port changes into disconnected state. After a connection is detected, USB port changes into connected state. The USB port changes into enabled state after a port reset is performed on USB bus.

Figure 28-4. State transition diagram of host port



Connection, Reset and Speed identification

As a USB host, USBFS will trigger a connection flag for application after a connection is detected and will trigger a disconnection flag after a disconnection event.

PRST bit in USBFS_HPCS register is used for USB reset sequence. Application may set this bit to start a USB reset and clear this bit to finish the USB reset. This bit only takes effect when port is at connected or enabled state.

The USBFS performs speed identification during connection, and the speed information will be reported in PS field in USBFS_HPCS register. USBFS identifies the device speed by the voltage level of DM or DP. As described in USB protocol, full-speed device pulls up DP line, while low-speed device pulls up DM line.

Suspend and resume

USBFS supports suspend state and resume operation. When USBFS port is at enabled state, writing 1 to PSP bit in USBFS_HPCS register will cause USBFS to enter into suspend state. In suspend state, USBFS stops sending SOFs on USB bus, and it will lead the connected USB device to enter into suspend state after 3ms. Application can set the PREM bit in USBFS_HPCS register to start a resume sequence, so as to wake up the suspended device, and clear this bit to stop the resume sequence. The WKUPIF bit in USBFS_GINTF will be set and the USBFS wakeup interrupt will be triggered if a host in suspend state detects a remote wakeup signal.

SOF generate

USBFS sends SOF tokens on USB bus in host mode. As described in USB 2.0 protocol, SOF packets are generated (by the host controller or hub transaction translator) every 1ms in full-speed links.

Once that USBFS entered into enabled state, it will send the SOF packet periodically and the period is defined in USB 2.0 protocol. In addition, application may adjust the length of a frame by writing FRI field in USBFS_HFT registers. The FRI bits define the number of USB clock cycles in a frame, so its value should be calculated based on the frequency of USB clock which is used by USBFS. The FRT field bits show that the remaining clock cycles of the current frame and it stops changing during suspend state.

USBFS is able to generate a pulse signal for each SOF packet and output it to a pin. The pulse length is 16 HCLK cycles. If application desires to use this function, it needs to set SOFOEN bit in USBFS_GCCFG register and configure the related pin registers in GPIO.

USB Channels and Transactions

USBFS includes 8 independent channels in host mode. Each channel is able to communicate with an endpoint in USB device. The transfer type, direction, packet length and other information are all configured in channel related registers such as USBFS_HCHxCTL and USBFS_HCHxLEN.

USBFS supports all the four types of transfer: control, bulk, interrupt and isochronous. USB

2.0 protocol divides these transfers into 2 kinds: non-periodic transfer (control and bulk) and periodic transfer (interrupt and isochronous). Based on this, USBFS includes two request queues: periodic request queue and non-periodic request queue, to perform efficient transaction schedule. A request entry in a request queue described above may represent a USB transaction request or a channel operation request.

Application needs to write packet into data FIFO via AHB bus if it wants to start an OUT transaction on USB bus. USBFS hardware will automatically generate a transaction request entry in request queue after the application writes a whole packet.

The request entries in request queue are processed in order by transaction control module. USBFS always tries to process periodic request queue firstly and secondly process non-periodic request queue.

After a start of frame, USBFS begins to process periodic queue until the queue is empty or bus time required by the current periodic request is not enough, and then process the non-periodic queue. This strategy ensures the bandwidth of periodic transactions in a frame. Each time the USBFS reads and pops a request entry from request queue. If the request is a channel disable request, it immediately disables the channel and prepares to process the next entry.

If the current request is a transaction request and the USB bus time is enough for this transaction, USBFS will employ SIE to generate this transaction on USB bus.

When the required bus time for the current request is not enough in the current frame, and this is a periodic request, USBFS stops processing the periodic queue and starts to process non-periodic request. If this is a non-periodic queue, the USBFS will stop processing any queue and wait until the end of current frame.

28.5.3. USB device function

USB Device Connection

In device mode, USBFS stays at power-off state after initialization. After connecting to a USB host with a 5V power supply through VBUS pin or setting VBUSIG bit in USBFS_GCCFG register, USBFS enters into power-on state. In this state, USBFS begins to switch on the pull-up resistor on DP line and then the host will detect a connection event.

Reset and Speed-Identification

The USB host always starts a USB reset sequence when it detects a device connection, and USBFS in device mode will trigger a reset interrupt by hardware when it detects the reset event on USB bus.

After the reset sequence, USBFS will trigger an ENUMF interrupt in USBFS_GINTF register and report current enumerated device speed by ES bits in USBFS_DSTAT register, the bit field is always 11(full-speed).

As described in USB 2.0 protocol, USBFS doesn’t support low-speed in device mode.

Suspend and Wake-up

A USB device will enter into suspend state if the USB bus stays at IDLE state and there is no change on data lines for 3ms. When USB device is in suspend state, most of its clocks are closed to save power. The USB host is able to wake up the suspended device by generating a resume signal on USB bus. When USBFS detects the resume signal, the WKUPIF flag in USBFS_GINTF register will be set and the USBFS wakeup interrupt will be triggered.

In suspend mode, USBFS is also able to remotely wake up the USB bus. Software may set RWKUP bit in USBFS_DCTL register to send a remote wakeup signal, and if remote wakeup is supported in USB host, the host will begin to send the resume signal on USB bus.

Soft Disconnection

USBFS supports soft disconnection. After the device is powered on, USBFS will switch on the pull-up resistor on DP line so that the host can detect the connection. It is able to force a disconnection by setting the SD bit in USBFS_DCTL register. After the SD bit is set, USBFS will directly switch off the pull-up resistor, so that USB host will detect a disconnection on USB bus.

SOF tracking

When USBFS receives a SOF packet on USB bus, it will trigger a SOF interrupt and begin to count the bus time by local USB clock. The frame number of the current frame is reported in FNRSOF field in USBFS_DSTAT register. When the USB bus time reaches EOF1 or EOF2 point (End of Frame, described in USB 2.0 protocol), USBFS will trigger an EOPFIF interrupt in USBFS_GINTF register. These flags and registers can be used to get current bus time and position information.

28.5.4. OTG function overview

USBFS supports OTG function described in OTG protocol 1.3, OTG function includes SRP and HNP protocols.

A-Device and B-Device

A-Device is an OTG capable USB device with a Standard-A or Micro-A plug inserted into its receptacle. The A-Device supplies power to VBUS and it is a host by default at the start of a session. B-Device is an OTG capable USB device with a Standard-B, Micro-B or Mini-B plug inserted into its receptacle, or a captive cable ending being a Standard-A plug. The B-Device is a peripheral by default at the start of a session. USBFS uses the voltage level of ID pin to identify A-Device or B-Device. The ID status is reported in IDPS bit in USBFS_GOTGCS register. For the details of transfer states between A-Device and B-Device, please refer to OTG 1.3 protocol.

HNP

The Host Negotiation Protocol (HNP) allows the host function to be switched between two directly connected On-The-Go devices and eliminates the necessity of switching the cable

connections for the change about control of communications between the devices. HNP will be initialized typically by the user or an application on the On-The-Go B-Device. HNP may only be implemented through the Micro-AB receptacle on a device.

Since On-The-Go devices have a Micro-AB receptacle, an On-The-Go device can be a host/device by default, depending on which type of plug (Micro-A plug for host, Micro-B plug for device) is inserted. By utilizing the Host Negotiation Protocol (HNP), an On-The-Go B-Device, which is the default device, may request to be a host. The process for changing the role to be a host is described in next section. This protocol eliminates the necessity of switching the cable connection for the roles change of the connected devices.

When USBFS is in OTG A-Device host mode and it wants to give up its host role, it may firstly set PSP bit in USBFS_HPCS register to make the USB bus enter into suspend status. Then, the B-Device will enter into suspend state 3ms later. If the B-Device wants to change to be a host, HNPREQ bit in USBFS_GOTGCS register should be set and the USBFS will begin to perform HNP protocol on bus, and at last, the result of HNP is reported in HNPS bit in USBFS_GOTGCS register. In additional, it is always available to get the current role (host or device) from COPM bit in USBFS_GINTF register by application.

SRP

The Session Request Protocol (SRP) allows a B-Device to request the A-Device to turn on VBUS and start a session. This protocol allows the A-Device, which may be battery powered, to save power by turning VBUS off when there is no bus activity, while still providing a means for the B-Device to initiate bus activity. As is described in OTG protocol, an OTG device must compare VBUS voltage with several threshold values, and the compared result should be reported in ASV and BSV bits in USBFS_GOTGCS register.

Set SRPREQ bit in USBFS_GOTGCS register to start a SRP request when USBFS is in OTG B-Device mode. USBFS will generate a success flag SRPS in USBFS_GOTGCS register if the SRP requests successfully.

When USBFS is in OTG A-Device mode and it has detected a SRP request from a B-Device, it sets a SESIF flag in USBFS_GINTF register. The 5V power supply for VBUS pin should be prepared to switch on after getting this flag.

28.5.5. Data FIFO

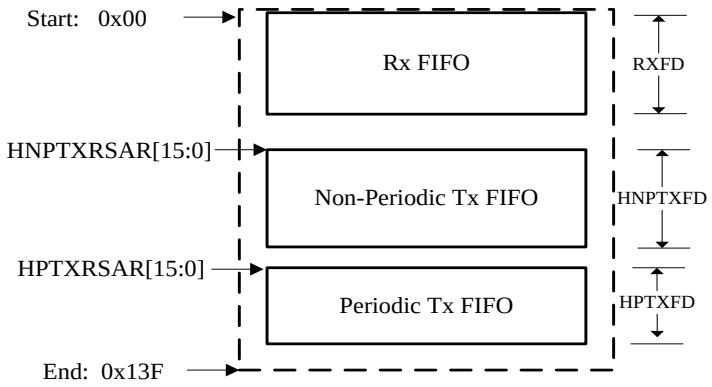
The USBFS contains a 1.25K bytes data FIFO for packet data storage. The data FIFO is implemented by using an internal SRAM in USBFS.

Host Mode

In host mode, the data FIFO space is divided into 3 parts: Rx FIFO for received packet, non-periodic Tx FIFO for non-period transmission packet and periodic Tx FIFO for periodic transmission packet. All IN channels shares the Rx FIFO for packets reception. All the periodic OUT channels share the periodic Tx FIFO for packets transmission. All the non-periodic OUT channels share the non-periodic FIFO for packets transmission. The size and

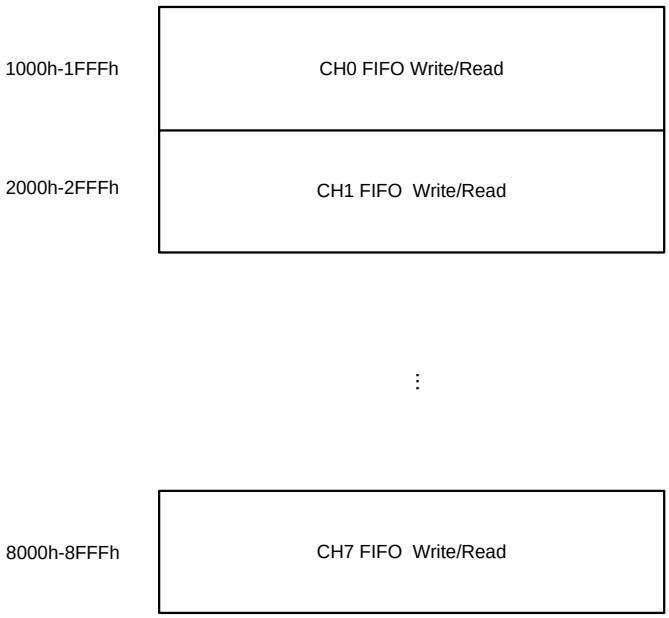
start offset of these data FIFOs should be configured using these registers: USBFS_GRFLEN, USBFS_HNPTFLEN and USBFS_HPTFLEN. ***Figure 28-5. HOST mode FIFO space in SRAM*** describes the structure of these FIFOs in SRAM. The values in the figure are in term of 32-bit words.

Figure 28-5. HOST mode FIFO space in SRAM



USBFS provides a special register area for the internal data FIFO reading and writing. ***Figure 28-6. Host mode FIFO access register mapping*** describes the register memory area that the data FIFO can access. The addresses in the figure are addressed in bytes. Each channel has its own FIFO access register space, although all non-periodic channels share the same FIFO and all the periodic channels also share the same FIFO. It is important for USBFS to get which channel the current pushed packet belongs to, and the Rx FIFO which the packet belongs to is also able to be accessed by using USBFS_GRSTATR/USBFS_GRSTATP register.

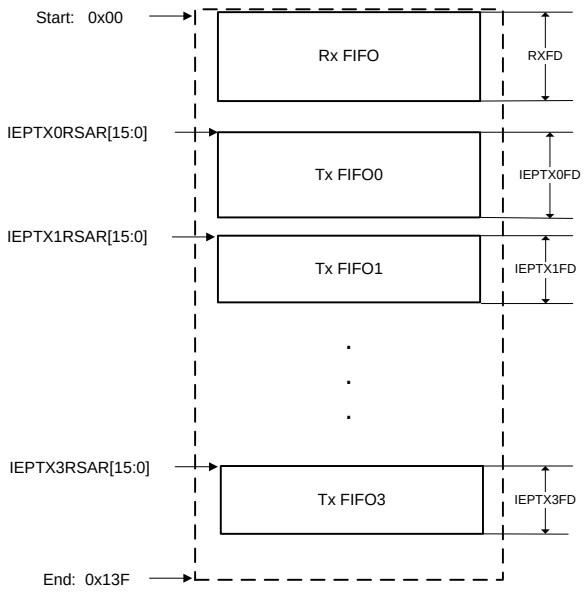
Figure 28-6. Host mode FIFO access register mapping



Device mode

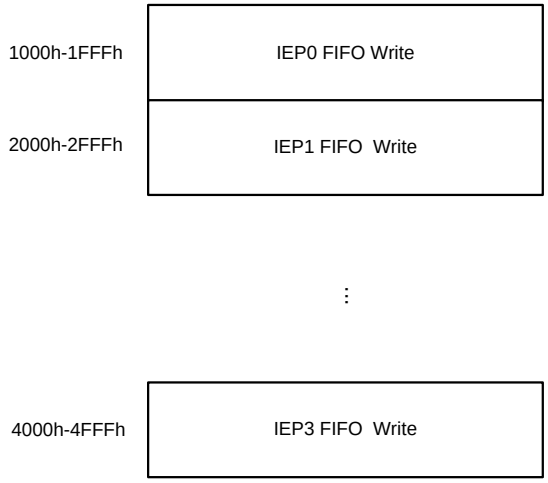
In device mode, the data FIFO is divided into several parts: 1 Rx FIFO, and 4 Tx FIFOs (one for each IN endpoint). All the OUT endpoints share the Rx FIFO for receiving packets. The size and start offset of these data FIFOs should be configured by using USBFS_GRFLEN and USBFS_DIEPxTFLEN (x=0…3) registers. ***Figure 28-7. Device mode FIFO space in SRAM*** describes the structure of these FIFOs in SRAM. The values in the figure are in term of 32-bit words.

Figure 28-7. Device mode FIFO space in SRAM



USBFS provides a special register area for the internal data FIFO reading and writing. ***Figure 28-8. Device mode FIFO access register mapping*** describes the register memory area where the data FIFO can access. The addresses in the figure are addressed in bytes. Each endpoint has its own FIFO access register space. Rx FIFO is also able to be accessed by using USBFS_GRSTATR/USBFS_GRSTATP register.

Figure 28-8. Device mode FIFO access register mappimg



28.5.6. Operation guide

This section describes the advised operation guide for USBFS.

Host mode

Global register initialization sequence

1. Program USBFS_GAHBCS register according to application's demand, such as the Tx FIFO's empty threshold, etc. GINTEN bit should be kept cleared at this time.
2. Program USBFS_GUSBCS register according to application's demand, such as the operation mode (host, device or OTG) and some parameters of OTG and USB protocols.
3. Program USBFS_GCCFG register according to application's demand.
4. Program USBFS_GRFLEN, USBFS_HNPTFLEN and USBFS_HPTFLEN register to configure the data FIFOs according to application's demand.
5. Program USBFS_GINTEN register to enable mode fault and host port interrupt and set GINTEN bit in USBFS_GAHBCS register to enable global interrupt.
6. Program USBFS_HPCS register to set PP bit.
7. Wait for a device's connection, and once a device is connected, the connection interrupt PCD in USBFS_HPCS register will be triggered. Then set PRST bit to perform a port reset. Wait for at least 10ms and then clear PRST bit.
8. Wait PEDC interrupt in USBFS_HPCS register and then read PE bit to ensure that the port is successfully enabled. Read PS [1:0] bits to get the connected device's speed and then program USBFS_HFT register to change the SOF interval if needed.

Channel initialization and enable sequence

1. Program USBFS_HCHxCTL registers with desired transfer type, direction, packet size, etc. Ensure that CEN and CDIS bits are kept cleared during configuration.
2. Program USBFS_HCHxINTEN register. Set the desired interrupt enable bits.
3. Program USBFS_HCHxLEN register. PCNT is the number of packets in a transfer and TLEN is the total bytes number of all the transmitted or received packets in a transfer.

For OUT channel: If PCNT=1, the single packet's size is equal to TLEN. If PCNT>1, the former PCNT-1 packets are considered as max-packet-lengthened packets whose size are defined by MPL field in USBFS_HCHxCTL register, and the last packet's size is calculated based on PCNT, TLEN and MPL. If software wants to send out a zero-lengthened packet, it should program TLEN=0, PCNT=1.

For IN channel: Because the application doesn't know the actual received data size before the IN transaction finishes, TLEN could be set to a maximum possible value supported by Rx FIFO.

4. Set CEN bit in USBFS_HCHxCTL register to enable the channel.

Channel disable sequence

Software can disable the channel by setting both CEN and CDIS bits at the same time. USBFS will generate a channel disable request entry in request queue after the register setting operation. When the request entry reaches the top of request queue, it will be processed by USBFS immediately:

For OUT channels, the specified channel will be disabled immediately. Then, a CH flag will be generated and the CEN and CDIS bits will be cleared by USBFS.

For IN channels, USBFS pushes a channel disable status entry into Rx FIFO. Then software should handle the Rx FIFO not empty event: read and pop this status entry, and then, a CH flag will be generated and the CEN and CDIS bits will be cleared.

IN transfers operation sequence

1. Initialize USBFS global registers.
2. Initialize the channel.
3. Enable the channel.
4. After the IN channel is enabled by software, USBFS generates an Rx request entry in the corresponding request queue.
5. When the Rx request entry reaches the top of the request queue, USBFS begins to process this request entry. If bus time for the IN transaction indicated by the request entry is enough, USBFS starts the IN transaction on USB bus.
6. If the IN transaction is finished successfully (ACK handshake received), USBFS pushes the received data packet into the Rx FIFO and triggers ACK flag. Otherwise, the status flag (NAK) reports the transaction result.
7. If the IN transaction described in step 5 is successful and PCNT is larger than 1 in step2, returns to step 3 and continues to receive the remaining packets. If the IN transaction described in step 5 is not successful, returns to step 3 to re-receive the packet again.
8. After all the transactions in a transfer have been successfully received on USB bus, USBFS pushes a TF status entry into the Rx FIFO on top of the last packet data. Thus after reading and popping all the received data packet, the TF status entry is read. USBFS generates TF flag to indicate that the transfer successfully have been finished.
9. Disable the channel. Now the channel is in IDLE state and is ready for other transfers.

OUT transfers operation sequence

1. Initialize USBFS global registers.
2. Initialize and enable the channel.
3. Write a packet into the channel’s Tx FIFO (Periodic Tx FIFO or non-periodic Tx FIFO).

After the whole packet data is written into the FIFO, USBFS generates a Tx request entry in the corresponding request queue and decreases the TLEN field in USBFS_HCHxLEN register by the written packet's size.

4. When the request entry reaches the top of the request queue, USBFS begins to process this request entry. If bus time for the transaction indicated by the request entry is enough, USBFS starts the OUT transaction on USB bus.
5. When the OUT transaction indicated by the request entry has been finished on USB bus, PCNT in USBFS_HCHxLEN register is decreased by 1. If the transaction is finished successfully (ACK handshake received), the ACK flag is triggered. Otherwise, the status flag (NAK) reports the transaction result.
6. If the OUT transaction described in step 5 is successful and PCNT is larger than 1 in step 2, returns to step 3 and continues to send the remaining packets. If the OUT transaction described in step 5 is not successful, return to step 3 to re-send the packet again.
7. After all the transactions in a transfer are successfully sent on USB bus, USBFS generates TF flag to indicate that the transfer successfully finishes.
8. Disable the channel. Now the channel is in IDLE state and is ready for other transfers.

Device mode

Global register initialization sequence

1. Program USBFS_GAHBCS register according to application's demand, such as the TxFIFO's empty threshold, etc. GINTEN bit should be kept cleared at this time.
2. Program USBFS_GUSBCS register according to application's demand, such as: the operation mode (host, device or OTG) and some parameters of OTG and USB protocols.
3. Program USBFS_GCCFG register according to application's demand.
4. Program USBFS_GRFLEN, USBFS_DIEP0TFLEN, USBFS_DIEPxTFLEN register to configure the data FIFOs according to application's demand.
5. Program USBFS_GINTEN register to enable Mode Fault, Suspend, SOF, Enumeration Done and USB Reset interrupt, and then, set GINTEN bit in USBFS_GAHBCS register to enable global interrupt.
6. Program USBFS_DCFG register according to application's demand, such as the device address, etc.
7. After the device is connected to a host, the host will perform port reset on USB bus and this will trigger the RST interrupt in USBFS_GINTF register.
8. Wait for ENUMF interrupt in USBFS_GINTF register.

Endpoint initialization and enable sequence

1. Program USBFS_DIEPxCTL or USBFS_DOEPxCTL register with desired transfer type, packet size, etc.
2. Program USBFS_DIEPINTEN or USBFS_DOEPINTEN register. Set the desired interrupt enable bits.
3. Program USBFS_DIEPxLEN or USBFS_DOEPxLEN register. PCNT is the number of packets in a transfer and TLEN is the total bytes number of all the transmitted or received packets in a transfer.

   For IN endpoint：If PCNT=1, the single packet’s size is equal to TLEN. If PCNT>1, the former PCNT-1 packets are considered as max-packet-length packets whose size are defined by MPL field in USBFS_DIEPxCTL register, and the last packet’s size is calculated based on PCNT, TLEN and MPL. If a zero-length packet is required to be sent, it should program TLEN=0, PCNT=1.

   For OUT endpoint：Because the application doesn’t know the actual received data size before the OUT transaction finishes, TLEN can be set to a maximum possible value supported by Rx FIFO.
4. Set EPEN bit in USBFS_DIEPxCTL or USBFS_DOEPxCTL register to enable the endpoint.

Endpoint disable sequence

The endpoint can be disabled anytime when the EPEN bit in USBFS_DIEPxCTL or USBFS_DOEPxCTL registers is cleared.

IN transfers operation sequence

1. Initialize USBFS global registers.
2. Initialize and enable the IN endpoint.
3. Write packets into the endpoint’s Tx FIFO. At any time, a data packet is written into the FIFO, USBFS decreases the TLEN field in USBFS_DIEPxLEN register by the written packet’s size.
4. When an IN token received, USBFS transmits the data packet, and after the transaction finishes on USB bus, PCNT in USBFS_DIEPxLEN register is decreased by 1. If the transaction finishes successfully (ACK handshake received), the ACK flag is triggered. Otherwise, the status flags reports the transaction result.
5. After all the data packets in a transfer have been successfully sent on USB bus, USBFS generates TF flag to indicate that the transfer successfully is finished and the IN endpoint is disabled.

OUT transfers operation sequence

1. Initialize USBFS global registers.
2. Initialize the endpoint and enable the endpoint.

3. When an OUT token is received, USBFS receives the data packet or response with an NAK handshake based on the status of Rx FIFO and register configuration. If the transaction is finished successfully (USBFS receives and saves the data packet into Rx FIFO successfully and sends ACK handshake on USB bus), PCNT in USBFS_DOEPxLEN register is decreased by 1 and the ACK flag is triggered, otherwise, the status flags report the transaction result.

4. After all the data packets in a transfer are successfully received on USB bus, USBFS pushes a TF status entry into the Rx FIFO on top of the last packet data. Thus, after reading and popping all the received data packet, the TF status entry is read. USBFS generates TF flag to indicate that the transfer is successfully finished and the IN endpoint is disabled.

28.6. Interrupts

USBFS has two interrupts: global interrupt and wakeup interrupt.

The source flags of the global interrupt are readable in USBFS_GINTF register and are listed in ***Table 28-2. USBFS global interrupt***.

Table 28-2. USBFS global interrupt

Interrupt Flag	Description	Operation Mode
SEIF	Session interrupt	Host or device mode
DISCIF	Disconnect interrupt flag	Host Mode
IDPSC	ID pin status change	Host or device mode
PTXFEIF	Periodic Tx FIFO empty interrupt flag	Host Mode
HCIF	Host channels interrupt flag	Host Mode
HPIF	Host port interrupt flag	Host Mode
ISOONCIF/PXNCIF	Isochronous OUT transfer not complete interrupt flag / Periodic transfer not complete interrupt flag	Host or device mode
ISOINCIF	Isochronous IN transfer not complete interrupt flag	Device mode
OEPIF	OUT endpoint interrupt flag	Device mode
IEPIF	IN endpoint interrupt flag	Device mode
EOPFIF	End of periodic frame interrupt flag	Device mode
ISOOPDIF	Isochronous OUT packet dropped interrupt flag	Device mode

Interrupt Flag	Description	Operation Mode
ENUMF	Enumeration finished	Device mode
RST	USB reset	Device mode
SP	USB suspend	Device mode
ESP	Early suspend	Device mode
GONAK	Global OUT NAK effective	Device mode
GNPINAK	Global IN Non-Periodic NAK effective	Device mode
NPTXFEIF	Non-Periodic Tx FIFO empty interrupt flag	Host Mode
RXFNEIF	Rx FIFO non-empty interrupt flag	Host or device mode
SOF	Start of frame	Host or device mode
OTGIF	OTG interrupt flag	Host or device mode
MFIF	Mode fault interrupt flag	Host or device mode

Wakeup interrupt can be triggered when USBFS is in suspend state, even if when the USBFS's clocks are stopped. The source of the wakeup interrupt is WKUPIF bit in USBHS_GINTF register.

28.7. Register definition

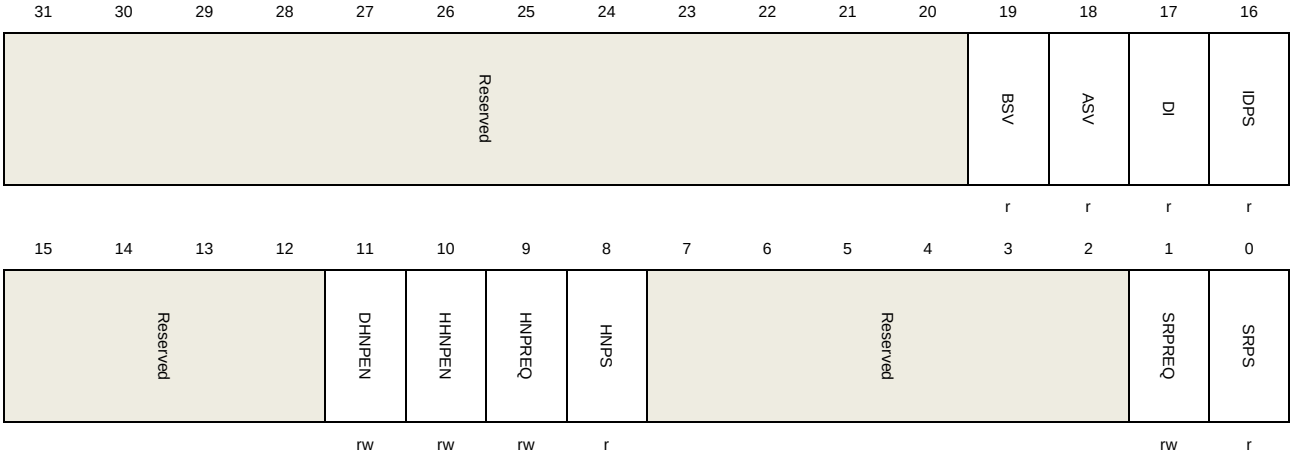
USBFS base address: 0x5000 0000

28.7.1. Global control and status registers

Global OTG control and status register (USBFS_GOTGCS)

Address offset: 0x0000
Reset value: 0x0000 0800

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:20	Reserved	Must be kept at reset value.
19	BSV	B-Session Valid (described in OTG protocol). 0: Vbus voltage level of a OTG B-Device is below $V_{BSESSVLD}$ 1: Vbus voltage level of a OTG B-Device is not below $V_{BSESSVLD}$ **Note:** Only accessible in OTG B-Device mode.
18	ASV	A- Session valid A-host mode transceiver status. 0: Vbus voltage level of a OTG A-Device is below $V_{ASESSVLD}$ 1: Vbus voltage level of a OTG A-Device is below $V_{ASESSVLD}$ The A-Device is the default host at the start of a session. **Note:** Only accessible in OTG A-Device mode.
17	DI	Debounce interval Debounce interval of a detected connection. 0: Indicates the long debounce interval, when a plug-on and connection occurs on USB bus 1: Indicates the short debounce interval, when a soft connection is used in HNP

		protocol. **Note:** Only accessible in host mode.
16	IDPS	ID pin status Voltage level of connector ID pin 0: USBFS is in A-Device mode 1: USBFS is in B-Device mode **Note:** Accessible in both device and host modes.
15:12	Reserved	Must be kept at reset value.
11	DHNPEN	Device HNP enable Enable the HNP function of a B-Device. If this bit is cleared, USBFS doesn't start HNP protocol when application set HNPREQ bit in USBFS_GOTGCS register. 0: HNP function is not enabled. 1: HNP function is enabled **Note:** Only accessible in device mode.
10	HHNPEN	Host HNP enable Enable the HNP function of an A-Device. If this bit is cleared, USBFS doesn't response to the HNP request from B-Device. 0: HNP function is not enabled. 1: HNP function is enabled **Note:** Only accessible in host mode.
9	HNPREQ	HNP request This bit is set by software to start a HNP on the USB. When HNPEND bit in USBFS_GOTGINTF register is set, this bit can be cleared by writing zero to it, or clearing the HNPEND bit in USBFS_GOTGINTF register. 0: Don't send HNP request 1: Send HNP request **Note:** Only accessible in device mode.
8	HNPS	HNP successes This bit is set by the core when HNP success, and this bit is cleared when HNPREQ bit is set. 0: HNP failure 1: HNP success **Note:** Only accessible in device mode.
7:2	Reserved	Must be kept at reset value.
1	SRPREQ	SRP request This bit is set by software to start a SRP on the USB. When SRPEND bit in USBFS_GOTGINTF register is set, this bit can be cleared by writing zero to it, or clearing the SRPEND bit in USBFS_GOTGINTF register. 0: No session request 1: Session request

Note: Only accessible in device mode.

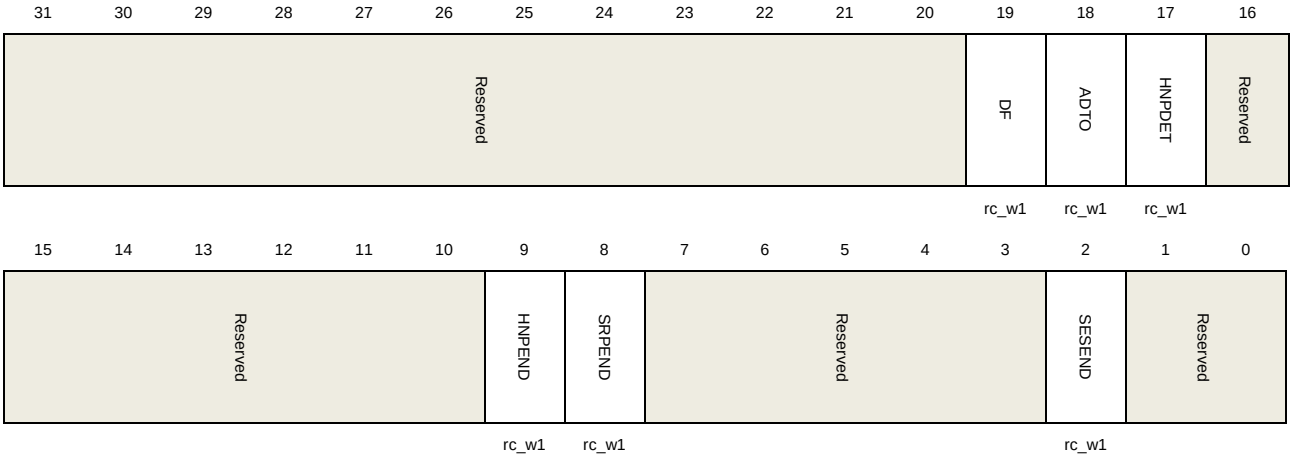
0	SRPS	SRP success flag This bit is set by the core when SRP succeeds, and this bit is cleared when SRPREQ bit is set. 0: SRP failure 1: SRP success **Note:** Only accessible in device mode.

Global OTG interrupt flag register (USBFS_GOTGINTF)

Address offset: 0x0004

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:20	Reserved	Must be kept at reset value.
19	DF	Debounce finish Set by USBFS when the debounce is done during device connection. **Note:** Only accessible in host mode.
18	ADTO	A-Device timeout Set by USBFS when it is timed out for the A-Device waiting for a B-Device connection. **Note:** Accessible in both device and host modes.
17	HNPDET	Host negotiation request detected Set by USBFS when A-Device detects a HNP request. **Note:** Accessible in both device and host modes.
16:10	Reserved	Must be kept at reset value.
9	HNPEND	HNP end

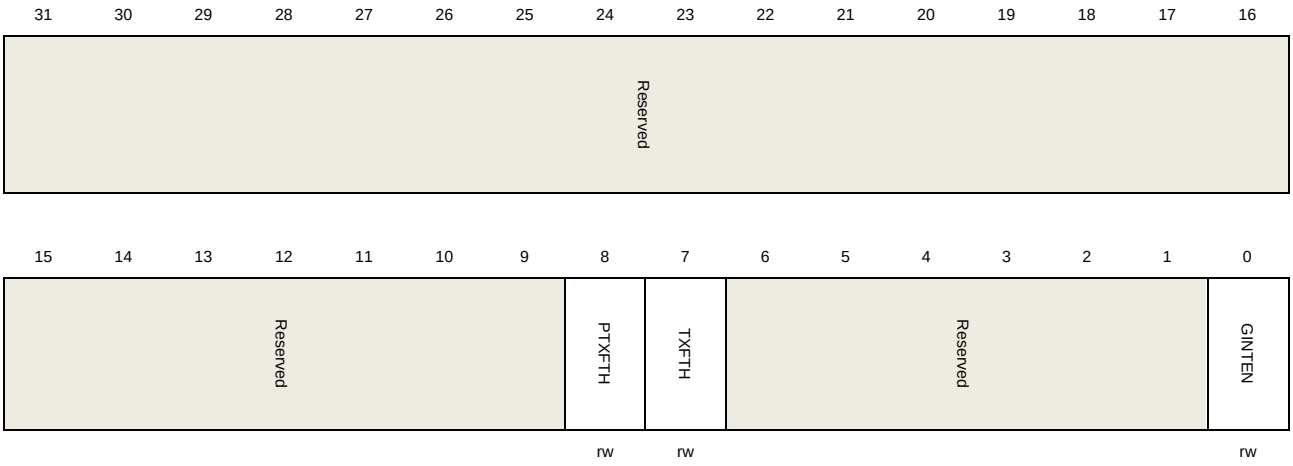
		Set by the core when a HNP ends. Read the HNPS in USBFS_GOTGCS register to get the result of HNP. **Note:** Accessible in both device and host modes.
8	SRPEND	SRPEND Set by the core when a SRP ends. Read the SRPS in USBFS_GOTGCS register to get the result of SRP. **Note:** Accessible in both device and host modes.
7:3	Reserved	Must be kept at reset value.
2	SESEND	Session end Set by the core when VBUS voltage is below $V_{b\_ses\_vld}$.
1:0	Reserved	Must be kept at reset value.

Global AHB control and status register (USBFS_GAHBCS)

Address offset: 0x0008

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:9	Reserved	Must be kept at reset value.
8	PTXFTH	Periodic Tx FIFO threshold 0: PTXFEIF will be triggered when the periodic Tx FIFO is half empty 1: PTXFEIF will be triggered when the periodic Tx FIFO is completely empty **Note:** Only accessible in host mode.
7	TXFTH	Tx FIFO threshold **Device mode**: 0: TXFEIF will be triggered when the IN endpoint Tx FIFO is half empty 1: TXFEIF will be triggered when the IN endpoint Tx FIFO is completely empty

Host mode:

0: NPTXFEIF will be triggered when the non-periodic Tx FIFO is half empty

1: NPTXFEIF will be triggered when the non-periodic Tx FIFO is completely empty

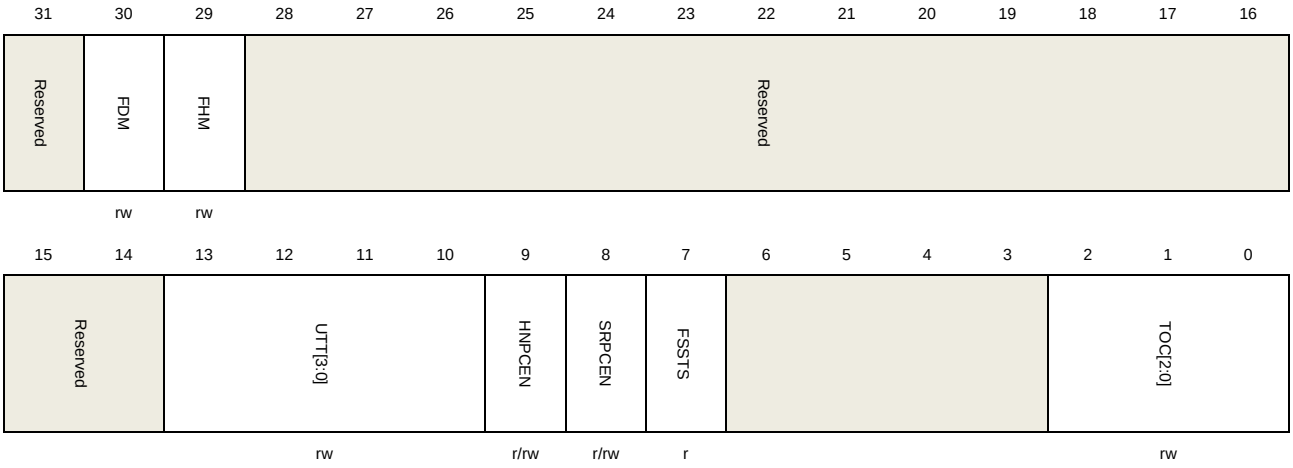
6：1	Reserved	Must be kept at reset value.
0	GINTEN	Global interrupt enable 0: Global interrupt is not enabled. 1: Global interrupt is enabled. **Note:** Accessible in both device and host modes.

Global USB control and status register (USBFS_GUSBCS)

Address offset: 0x000C

Reset value: 0x0000 0A80

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30	FDM	Force device mode Setting this bit will force the core to device mode irrespective of the USBFS ID input pin. 0: Normal mode 1: Device mode The application must wait at least 25 ms for the change taking effect after setting the force bit. **Note:** Accessible in both device and host modes.
29	FHM	Force host mode Setting this bit will force the core to host mode irrespective of the USBFS ID input pin. 0: Normal mode

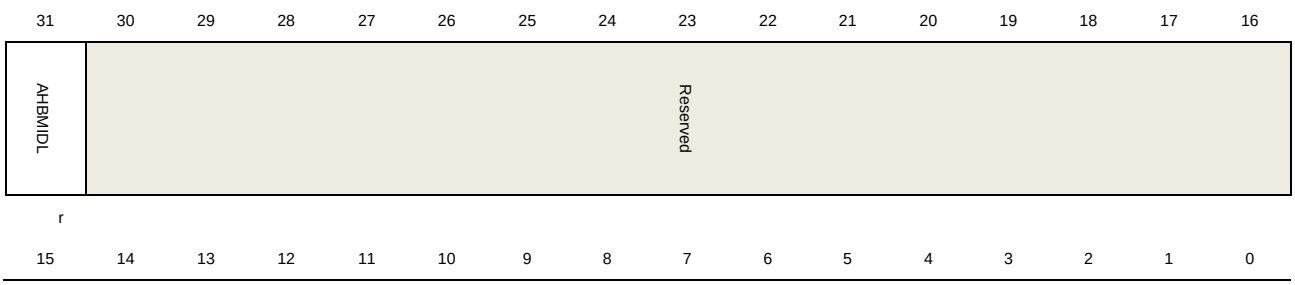
		1: Host mode The application must wait at least 25 ms for the change taking effect after setting the force bit. **Note:** Accessible in both device and host modes.
28:14	Reserved	Must be kept at reset value.
13:10	UTT[3:0]	USB turnaround time Turnaround time in PHY clocks. **Note:** Only accessible in device mode.
9	HNPCEN	HNP capability enable Controls whether the HNP capability is enabled 0: HNP capability is disabled 1: HNP capability is enabled **Note:** Accessible in both device and host modes.
8	SRPCEN	SRP capability enable Controls whether the SRP capability is enabled 0: SRP capability is disabled 1: SRP capability is enabled **Note:** Accessible in both device and host modes.
7	FSSTS	Full speed serial transceiver select, always 1 with read only
6:3	Reserved	Must be kept at reset value.
2:0	TOC[2:0]	Timeout calibration USBFS always uses time-out value required in USB 2.0 when waiting for a packet. The TOC bits are used to add the value in terms of PHY clock. (The frequency of PHY clock is 48MHz.).

Global reset control register (USBFS_GRSTCTL)

Address offset: 0x0010
Reset value: 0x8000 0000

The application uses this register to reset various hardware features inside the core.

This register has to be accessed by word (32-bit)



Reserved	TXFNUM[4:0]	TXFF	RXFF	Reserved	HFCRST	HCSRST	CSRST
	rw	rs	rs		rs	rs	rs

Bits	Fields	Descriptions
31	AHBMIDL	AHB master idle, this bit is always 1 for both device and host mode
30:11	Reserved	Must be kept at reset value.
10:6	TXFNUM[4:0]	Tx FIFO number Indicates which Tx FIFO will be flushed when TXFF bit in the same register is set. **Host Mode:** 00000: Only non-periodic Tx FIFO is flushed 00001: Only periodic Tx FIFO is flushed 1XXXX: Both periodic and non-periodic Tx FIFOs are flushed Other: No data FIFO is flushed **Device Mode:** 00000: Only Tx FIFO0 is flushed 00001: Only Tx FIFO1 is flushed … 00011: Only Tx FIFO3 is flushed 1XXXX: All Tx FIFOs are flushed Other: Non data FIFO is flushed
5	TXFF	Tx FIFO flush Set the bit to flush data Tx FIFOs and TXFNUM[4:0] bits determine the FIFO number to be flushed. Hardware automatically clears this bit after the flush process completes. After setting this bit, application should wait until this bit is cleared before any other operation on USBFS. **Note:** Accessible in both device and host modes.
4	RXFF	Rx FIFO flush Set the bit to flush data Rx FIFO. Hardware automatically clears this bit after the flush process completes. After setting this bit, application should wait until this bit is cleared before any other operation on USBFS. **Note:** Accessible in both device and host modes.
3	Reserved	Must be kept at reset value.
2	HFCRST	Host frame counter reset Set by the application to reset the frame number counter in USBFS. After this bit is set, the frame number of the following SOF returns to 0. Hardware automatically clears this bit after the reset process completes. After setting this bit, application should wait until this bit is cleared before any other operation on USBFS.

Note: Only accessible in host mode.

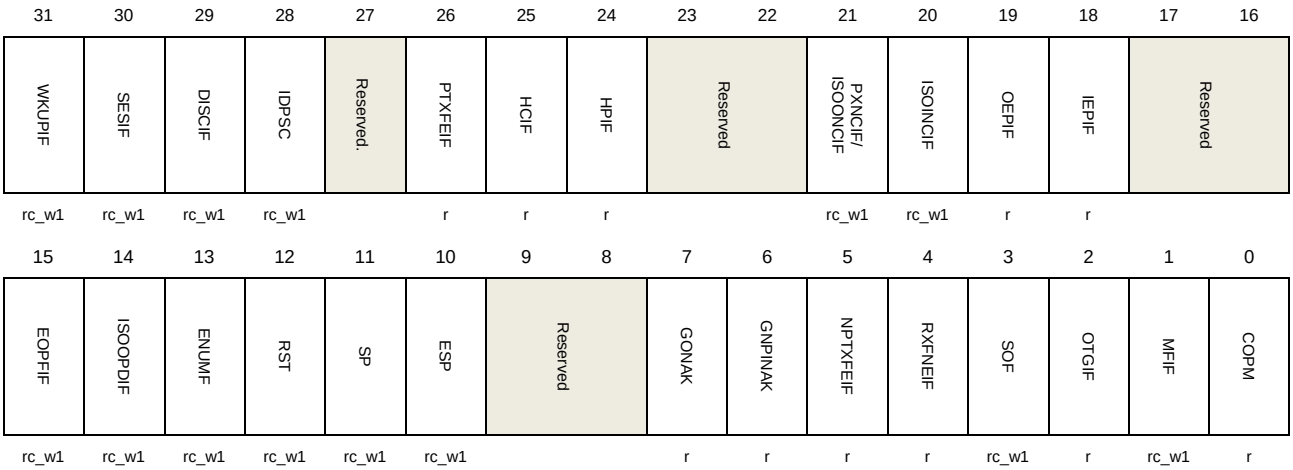
1	HCSRST	HCLK soft reset Set by the application to reset AHB clock domain circuit. Hardware automatically clears this bit after the reset process completes. After setting this bit, application should wait until this bit is cleared before any other operation on USBFS. **Note:** Accessible in both device and host modes.
0	CSRST	Core soft reset Resets the AHB and USB clock domains circuits, as well as most of the registers.

Global interrupt flag register (USBFS_GINTF)

Address offset: 0x0014

Reset value: 0x0400 0021

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	WKUPIF	Wakeup interrupt flag This interrupt is triggered when a resume signal (in device mode) or a remote wakeup signal (in host mode) is detected on the USB. **Note:** Accessible in both device and host modes.
30	SESIF	Session interrupt flag This interrupt is triggered when a SRP is detected (in A-Device mode) or VBUS becomes valid for a B- Device (in B-Device mode). **Note:** Accessible in both device and host modes.
29	DISCIF	Disconnect interrupt flag This interrupt is triggered after a device disconnection. **Note:** Only accessible in host mode.
28	IDPSC	ID pin status change

		Set by the core when ID status changes. **Note:** Accessible in both device and host modes.
27	Reserved	Must be kept at reset value.
26	PTXFEIF	Periodic Tx FIFO empty interrupt flag This interrupt is triggered when the periodic Tx FIFO is either half or completely empty. The threshold is determined by the periodic Tx FIFO empty level bit (PTXFTH) in the USBFS_GAHBCS register. **Note:** Only accessible in host mode.
25	HCIF	Host channels interrupt flag Set by USBFS when one of the channels in host mode has raised an interrupt. First read USBFS_ HACHINT register to get the channel number, and then read the corresponding USBFS_HCHxINTF register to get the flags of the channel that cause the interrupt. This bit will be automatically cleared after the respective channel's flags which cause channel interrupt are cleared. **Note:** Only accessible in host mode.
24	HPIF	Host port interrupt flag Set by the core when USBFS has detected the port status changes in host mode. Software should read USBFS_HPCS register to get the source of this interrupt. This bit will be automatically cleared after the flags that causing a port interrupt are cleared. **Note:** Only accessible in host mode.
23:22	Reserved	Must be kept at reset value.
21	PXNCIF	Periodic transfer Not Complete Interrupt flag USBFS sets this bit when there are periodic transactions not completed at the end of current frame (Host mode).
	ISOONCIF	Isochronous OUT transfer Not Complete Interrupt Flag At the end of a periodic frame (defined by EOPFT bit in USBFS_DCFG), USBFS will set this bit if there are still isochronous OUT endpoints for the transactions not completed (Device Mode).
20	ISOINCIF	Isochronous IN transfer Not Complete Interrupt Flag At the end of a periodic frame (defined by EOPFT bit in USBFS_DCFG), USBFS will set this bit if there are still isochronous OUT endpoints for the transactions not completed (Device Mode). **Note:** Only accessible in device mode.
19	OEPIF	OUT endpoint interrupt flag Set by USBFS when one of the OUT endpoints in device mode has raised an interrupt. Software should first read USBFS_DAEPINT register to get the endpoint number, and then read the corresponding USBFS_DOEPxINTF register to get the flags of the endpoint that cause the interrupt. This bit will be automatically cleared

		after the respective endpoint's flags which cause this interrupt are cleared. **Note:** Only accessible in device mode.
18	IEPIF	IN endpoint interrupt flag Set by USBFS when one of the IN endpoints in device mode has raised an interrupt. Software should first read USBFS_DAEPINT register to get the endpoint number, and then read the corresponding USBFS_DIEPxINTF register to get the flags of the endpoint that cause the interrupt. This bit will be automatically cleared after the respective endpoint's flags which cause this interrupt are cleared. **Note:** Only accessible in device mode.
17:16	Reserved	Must be kept at reset value.
15	EOPFIF	End of periodic frame interrupt flag When USB bus time in a frame reaches the value defined by EOPFT [1:0] bits in USBFS_DCFG register, USBFS sets this flag. **Note:** Only accessible in device mode.
14	ISOOPDIF	Isochronous OUT packet dropped interrupt flag USBFS sets this bit if it receives an isochronous OUT packet but cannot save it into Rx FIFO as it doesn't have enough space. **Note:** Only accessible in device mode.
13	ENUMF	Enumeration finished USBFS sets this bit after the speed enumeration finishes. Read USBFS_DSTAT register to get the current device speed. **Note:** Only accessible in device mode.
12	RST	USB reset USBFS sets this bit when it detects a USB reset signal on bus. **Note:** Only accessible in device mode.
11	SP	USB suspend USBFS sets this bit when it detects that the USB bus is idle for 3 ms and enters suspend state. **Note:** Only accessible in device mode.
10	ESP	Early suspend USBFS sets this bit when it detects that the USB bus is idle for 3 ms. **Note:** Only accessible in device mode.
9:8	Reserved	Must be kept at reset value.
7	GONAK	Global OUT NAK effective Write 1 to SGONAK bit in the USBFS_DCTL register and USBFS will set this flag after the SGONAK takes effect. **Note:** Only accessible in device mode.
6	GNPINAK	Global Non-Periodic IN NAK effective

		Write 1 to SGINAK bit in the USBFS_DCTL register and USBFS will set this flag after the SGINAK takes effect. **Note:** Only accessible in device mode.
5	NPTXFEIF	Non-Periodic Tx FIFO empty interrupt flag This interrupt is triggered when the non-periodic Tx FIFO is either half or completely empty. The threshold is determined by the non-periodic Tx FIFO empty level bit (TXFTH) in the USBFS_GAHBCS register. **Note:** Only accessible in host mode.
4	RXFNEIF	Rx FIFO non-empty interrupt flag USBFS sets this bit when there is at least one packet or status entry in the Rx FIFO. **Note:** Accessible in both host and device modes.
3	SOF	Start of frame **Host Mode:** USBFS sets this bit when it prepares to transmit a SOF or Keep-Alive on USB bus. This bit can be cleared by writing 1. **Device Mode:** USBFS sets this bit after it receives a SOF token. The application can read the Device Status register to get the current frame number. This bit can be cleared by writing 1. **Note:** Accessible in both host and device modes.
2	OTGIF	OTG interrupt flag USBFS sets this bit when the flags in USBFS_GOTGINTF register generate an interrupt. Software should read USBFS_GOTGINTF register to get the source of this interrupt. This bit is cleared after the flags in USBFS_GOTGINTF causing this interrupt are cleared. **Note:** Accessible in both host and device modes.
1	MFIF	Mode fault interrupt flag USBFS sets this bit when software operates host-only register in device mode, or operates device-only register in host mode. These fault operations won't take effect. **Note:** Accessible in both host and device modes.
0	COPM	Current operation mode 0: Device mode 1: Host mode **Note:** Accessible in both host and device modes.

Global interrupt enable register (USBFS_GINTEN)

Address offset: 0x0018

Reset value: 0x0000 0000

This register works with the global interrupt flag register (USBFS_GINTF) to interrupt the application. When an interrupt enable bit is disabled, the interrupt associated with that bit is not generated. However, the global Interrupt flag register bit corresponding to that interrupt is still set.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Fields	Descriptions
31	WKUPIE	Wakeup interrupt enable 0: Disable wakeup interrupt 1: Enable wakeup interrupt **Note:** Accessible in both host and device modes.
30	SESIE	Session interrupt enable 0: Disable session interrupt 1: Enable session interrupt **Note:** Accessible in both host and device modes.
29	DISCIE	Disconnect interrupt enable 0: Disable disconnect interrupt 1: Enable disconnect interrupt **Note:** Only accessible in device mode.
28	IDPSCIE	ID pin status change interrupt enable 0: Disable connector ID pin status interrupt 1: Enable connector ID pin status interrupt **Note:** Accessible in both host and device modes.
27	Reserved	Must be kept at reset value.
26	PTXFEIE	Periodic Tx FIFO empty interrupt enable 0: Disable periodic Tx FIFO empty interrupt 1: Enable periodic Tx FIFO empty interrupt **Note:** Only accessible in host mode.

25	HCIE	Host channels interrupt enable 0: Disable host channels interrupt 1: Enable host channels interrupt **Note:** Only accessible in host mode.
24	HPIE	Host port interrupt enable 0: Disable host port interrupt 1: Enable host port interrupt **Note:** Only accessible in host mode.
23:22	Reserved	Must be kept at reset value.
21	PXNCIE	Periodic transfer not complete Interrupt enable 0: Disable periodic transfer not complete interrupt 1: Enable periodic transfer not complete interrupt **Note:** Only accessible in host mode.
	ISOONCIE	Isochronous OUT transfer not complete interrupt enable 0: Disable isochronous OUT transfer not complete interrupt 1: Enable isochronous OUT transfer not complete interrupt **Note:** Only accessible in device mode.
20	ISOINCIE	Isochronous IN transfer not complete interrupt enable 0: Disable isochronous IN transfer not complete interrupt 1: Enable isochronous IN transfer not complete interrupt **Note:** Only accessible in device mode.
19	OEPIE	OUT endpoints interrupt enable 0: Disable OUT endpoints interrupt 1: Enable OUT endpoints interrupt **Note:** Only accessible in device mode.
18	IEPIE	IN endpoints interrupt enable 0: Disable IN endpoints interrupt 1: Enable IN endpoints interrupt **Note:** Only accessible in device mode.
17:16	Reserved	Must be kept at reset value.
15	EOPFIE	End of periodic frame interrupt enable 0: Disable end of periodic frame interrupt 1: Enable end of periodic frame interrupt **Note:** Only accessible in device mode.
14	ISOOPDIE	Isochronous OUT packet dropped interrupt enable 0: Disable isochronous OUT packet dropped interrupt 1: Enable isochronous OUT packet dropped interrupt **Note:** Only accessible in device mode.

13	ENUMFIE	Enumeration finish enable 0: Disable enumeration finish interrupt 1: Enable enumeration finish interrupt **Note:** Only accessible in device mode.
12	RSTIE	USB reset interrupt enable 0: Disable USB reset interrupt 1: Enable USB reset interrupt **Note:** Only accessible in device mode.
11	SPIE	USB suspend interrupt enable 0: Disable USB suspend interrupt 1: Enable USB suspend interrupt **Note:** Only accessible in device mode.
10	ESPIE	Early suspend interrupt enable 0: Disable early suspend interrupt 1: Enable early suspend interrupt **Note:** Only accessible in device mode.
9:8	Reserved	Must be kept at reset value.
7	GONAKIE	Global OUT NAK effective interrupt enable 0: Disable global OUT NAK interrupt 1: Enable global OUT NAK interrupt **Note:** Only accessible in device mode.
6	GNPINAKIE	Global non-periodic IN NAK effective interrupt enable 0: Disable global non-periodic IN NAK effective interrupt 1: Enable global non-periodic IN NAK effective interrupt **Note:** Only accessible in device mode.
5	NPTXFEIE	Non-periodic Tx FIFO empty interrupt enable 0: Disable non-periodic Tx FIFO empty interrupt 1: Enable non-periodic Tx FIFO empty interrupt **Note:** Only accessible in Host mode.
4	RXFNEIE	Receive FIFO non-empty interrupt enable 0: Disable receive FIFO non-empty interrupt 1: Enable receive FIFO non-empty interrupt **Note:** Accessible in both device and host modes.
3	SOFIE	Start of frame interrupt enable 0: Disable start of frame interrupt 1: Enable start of frame interrupt **Note:** Accessible in both device and host modes.
2	OTGIE	OTG interrupt enable 0: Disable OTG interrupt

		1: Enable OTG interrupt **Note:** Accessible in both device and host modes.
1	MFIE	Mode fault interrupt enable 0: Disable mode fault interrupt 1: Enable mode fault interrupt **Note:** Accessible in both device and host modes.
0	Reserved	Must be kept at reset value.

Global receive status read/receive status read and pop registers (USBFS_GRSTATR/USBFS_GRSTATP)

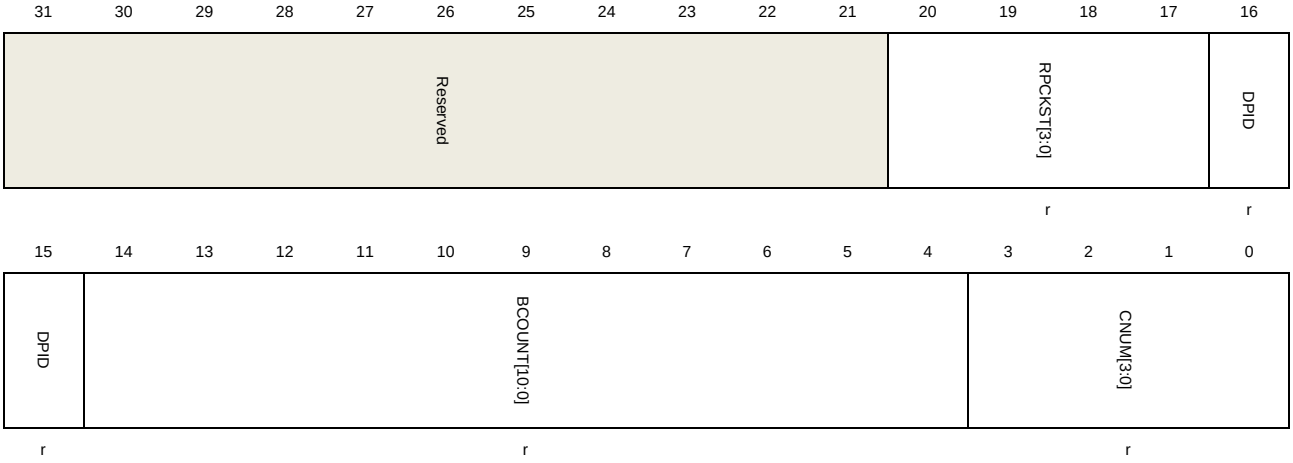
Address offset for Read: 0x001C
Address offset for Pop: 0x0020
Reset value: 0x0000 0000

A read to the receive status read register returns the entry of the top of the Rx FIFO. A read to the Receive status read and pop register additionally pops the top entry out of the Rx FIFO.

The entries in RxFIFO have different meanings in host and device modes. Software should only read this register after when Receive FIFO non-empty interrupt flag bit of the global interrupt flag register (RXFNEIF bit in USBFS_GINTF) is triggered.

This register has to be accessed by word (32-bit)

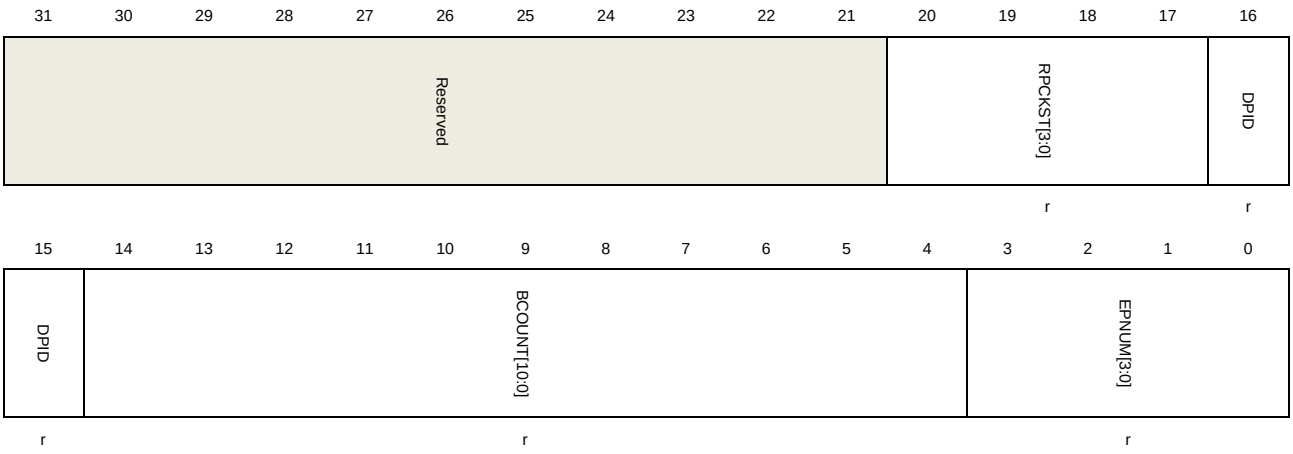
Host mode:



Bits	Fields	Descriptions
31:21	Reserved	Must be kept at reset value.
20:17	RPCKST[3:0]	Received packet status 0010: IN data packet received 0011: IN transfer completed (generates an interrupt if poped) 0101: Data toggle error (generates an interrupt if poped)

		0111: Channel halted (generates an interrupt if poped) Others: Reserved
16:15	DPID[1:0]	Data PID The Data PID of the received packet 00: DATA0 10: DATA1 01: DATA2 11: MDATA
14:4	BCOUNT[10:0]	Byte count The byte count of the received IN data packet.
3:0	CNUM[3:0]	Channel number The channel number to which the current received packet belongs.

Device mode:



Bits	Fields	Descriptions
31:21	Reserved	Must be kept at reset value.
20:17	RPCKST[3:0]	Received packet status 0001: Global OUT NAK (generates an interrupt) 0010: OUT data packet received 0011: OUT transfer completed (generates an interrupt) 0100: SETUP transaction completed (generates an interrupt) 0110: SETUP data packet received Others: Reserved
16:15	DPID[1:0]	Data PID The Data PID of the received OUT data packet 00: DATA0 10: DATA1 01: DATA2

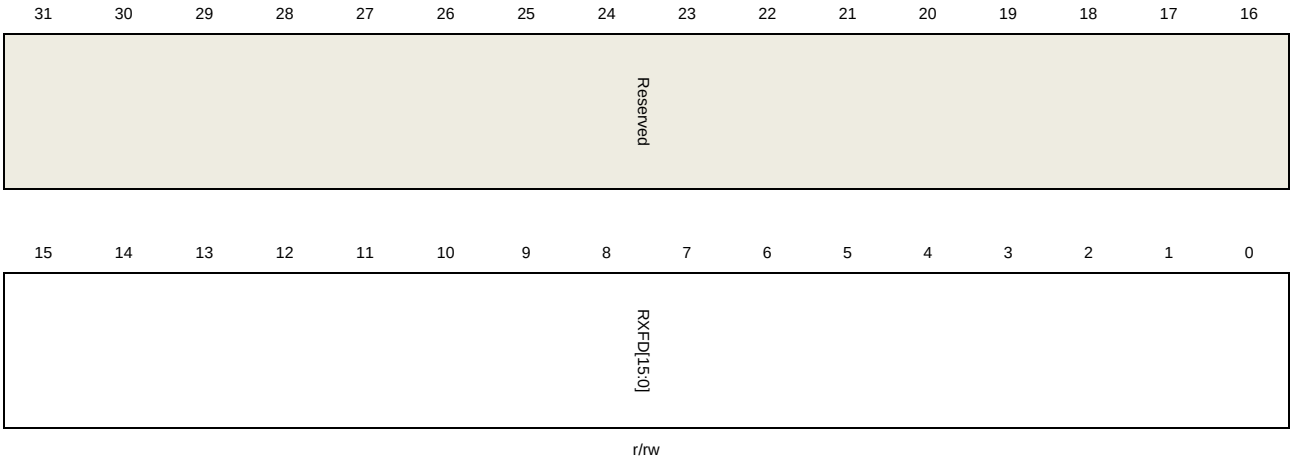
		11: MDATA
14:4	BCOUNT[10:0]	Byte count The byte count of the received data packet.
3:0	EPNUM[3:0]	Endpoint number The endpoint number to which the current received packet belongs.

Global receive FIFO length register (USBFS_GRFLEN)

Address offset: 0x024

Reset value: 0x0000 0200

This register has to be accessed by word (32-bit)



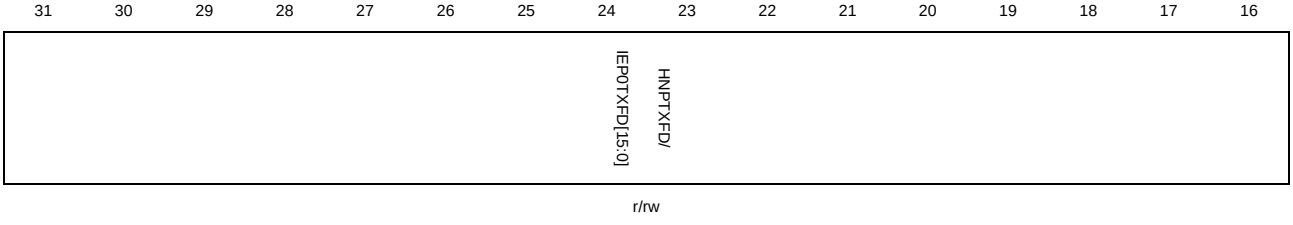
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value.
15:0	RXFD[15:0]	Rx FIFO depth In terms of 32-bit words. 1≤RXFD≤1024

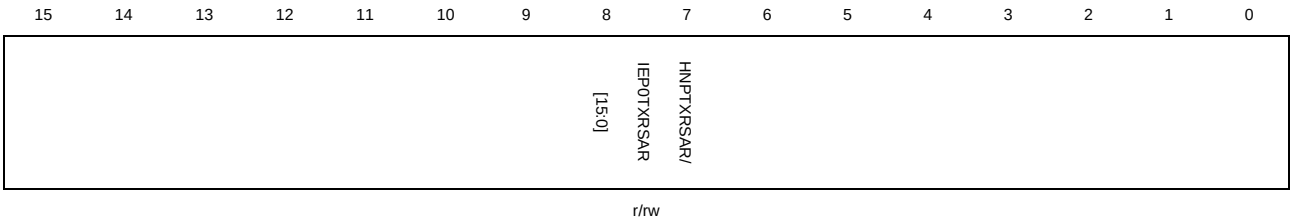
Host non-periodic Tx FIFO length register /Device IN endpoint 0 Tx FIFO length (USBFS_HNPTFLEN _DIEP0TFLEN)

Address offset: 0x028

Reset value: 0x0200 0200

This register has to be accessed by word (32-bit)





Host Mode:

Bits	Fields	Descriptions
31:16	HNPTXFD[15:0]	Host Non-periodic Tx FIFO depth In terms of 32-bit words. 1≤HNPTXFD≤1024
15:0	HNPTXRSAR[15:0]	Host Non-periodic Tx FIFO RAM start address The start address for non-periodic Tx FIFO RAM is in term of 32-bit words.

Device Mode:

Bits	Fields	Descriptions
31:16	IEP0TXFD[15:0]	IN Endpoint 0 Tx FIFO depth In terms of 32-bit words. 16≤IEP0TXFD≤140
15:0	IEP0TXRSAR[15:0]	IN Endpoint 0 TX RAM start address The start address for endpoint0 Tx FIFO RAM is in term of 32-bit words.

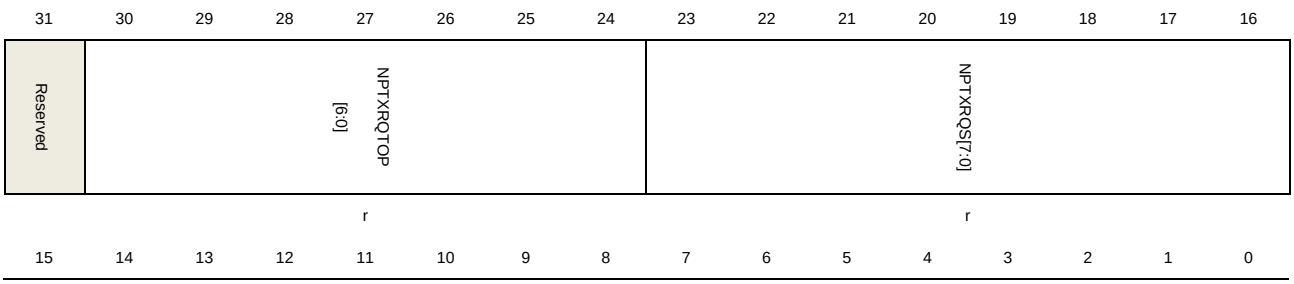
Host non-periodic Tx FIFO/queue status register (USBFS_HNPTFQSTAT)

Address offset: 0x002C
Reset value: 0x0008 0200

This register reports the current status of the non-periodic Tx FIFO and request queue. The request queue holds IN, OUT or other request entries in host mode.

Note: In Device mode, this register is not valid.

This register has to be accessed by word (32-bit)



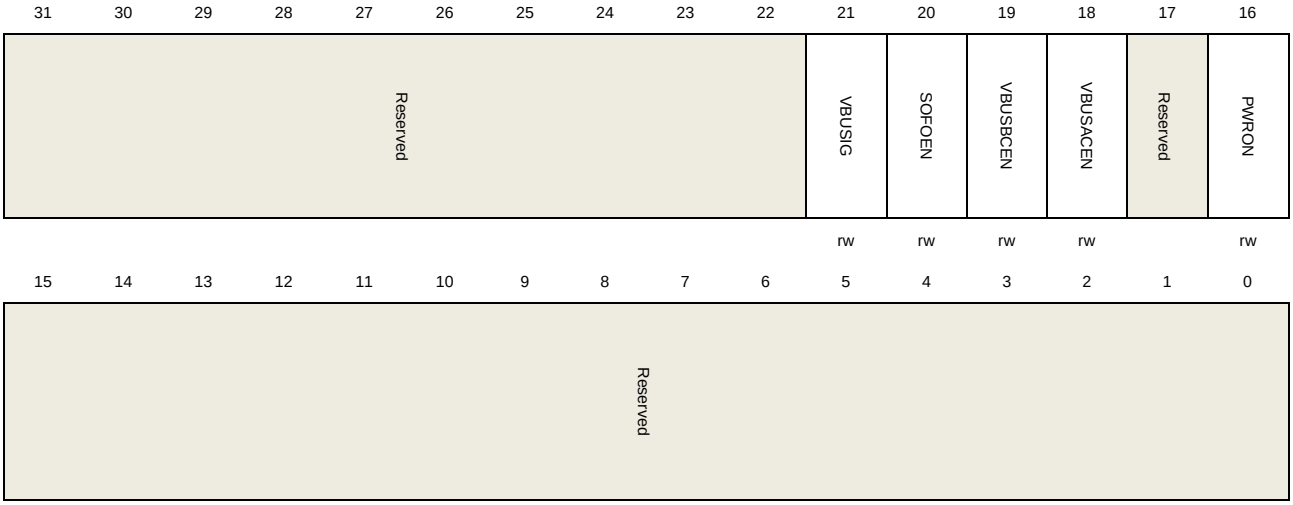
NPTXFS[15:0]
r

Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30:24	NPTXRQTOP[6:0]	Top entry of the non-periodic Tx request queue Entry in the non-periodic transmit request queue. Bits 30:27: Channel number Bits 26:25: – 00: IN/OUT token – 01: Zero-length OUT packet – 11: Channel halt request Bit 24: Terminate Flag, indicating last entry for selected channel.
23:16	NPTXRQS[7:0]	Non-periodic Tx request queue space The remaining space of the non-periodic transmit request queue. 0: Request queue is Full 1: 1 entry 2: 2 entries … n: n entries (0≤n≤8) Others: Reserved
15:0	NPTXFS[15:0]	Non-periodic Tx FIFO space The remaining space of the non-periodic Tx FIFO. In terms of 32-bit words. 0: Non-periodic Tx FIFO is full 1: 1 word 2: 2 words n: n words (0≤n≤NPTXFD) Others: Reserved

Global core configuration register (USBFS_GCCFG)

Address offset: 0x0038
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:22	Reserved	Must be kept at reset value.
21	VBUSIG	VBUS ignored When this bit is set, USBFS doesn't monitor the voltage on VBUS pin and always consider V_{BUS} voltage as valid both in host mode and in device mode, then free the V_{BUS} pin for other usage. 0: V_{BUS} is not ignored. 1: V_{BUS} is ignored and always consider VBUS voltage as valid.
20	SOFOEN	SOF output enable 0: SOF pulse output disabled. 1: SOF pulse output enabled.
19	VBUSBCEN	The V_{BUS} B-device comparer enable 0: V_{BUS} B-device comparer disabled 1: V_{BUS} B-device comparer enabled
18	VBUSACEN	The VBUS A-device comparer enable 0: V_{BUS} A-device comparer disabled 1: V_{BUS} A-device comparer enabled
17	Reserved	Must be kept at reset value.
16	PWRON	Power on This bit is the power switch for the internal embedded full-speed PHY. 0: Embedded full-speed PHY power off. 1: Embedded full-speed PHY power on.
15:0	Reserved	Must be kept at reset value.

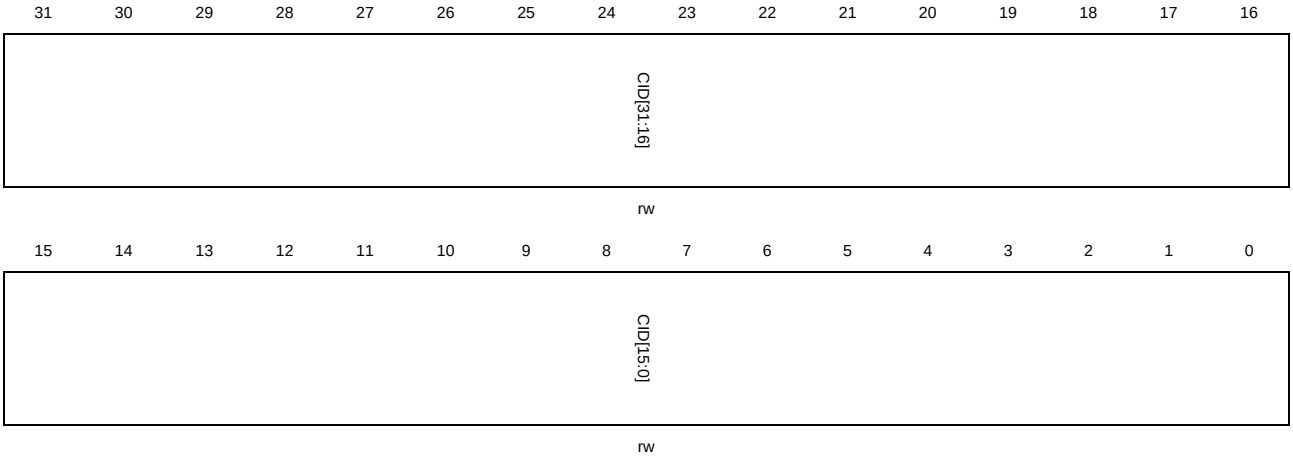
Core ID register (USBFS_CID)

Address offset: 0x003C

Reset value: 0x0000 1000

This register contains the Product ID.

This register has to be accessed by word (32-bit)



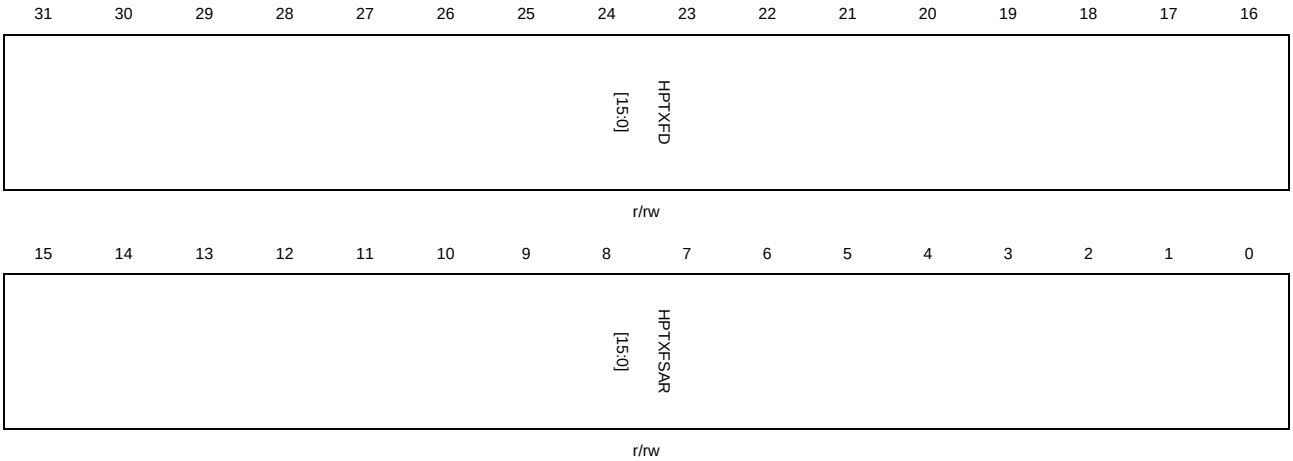
Bits	Fields	Descriptions
31:0	CID[31:0]	Core ID Software can write or read this field and uses this field as a unique ID for its application

Host periodic Tx FIFO length register (USBFS_HPTFLEN)

Address offset: 0x0100

Reset value: 0x0200 0600

This register has to be accessed by word 32-bit)

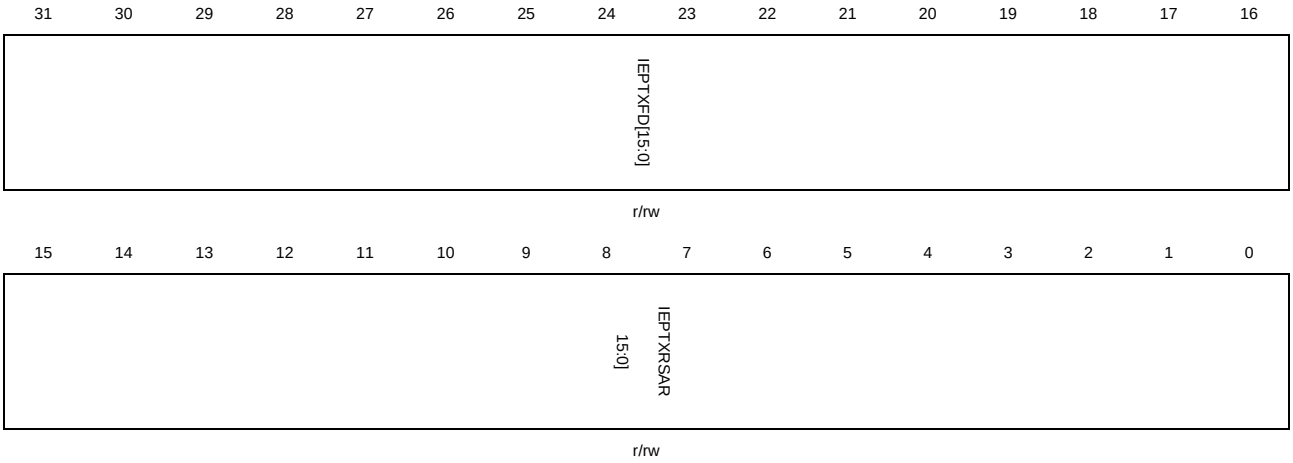


Bits	Fields	Descriptions
31:16	HPTXFD[15:0]	Host periodic Tx FIFO depth In terms of 32-bit words. 1≤HPTXFD≤1024
15:0	HPTXFSAR[15:0]	Host periodic Tx FIFO RAM start address The start address for host periodic Tx FIFO RAM is in term of 32-bit words.

Device IN endpoint Tx FIFO length register (USBFS_DIEPxTFLEN) (x = 1..3, where x is the FIFO_number)

Address offset: 0x0104 + (FIFO_number – 1) × 0x04
Reset value: 0x0200 0400

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:16	IEPTXFD[15:0]	IN endpoint Tx FIFO depth In terms of 32-bit words. 1≤HPTXFD≤1024
15:0	IEPTXRSAR[15:0]	IN endpoint Tx FIFO RAM start address The start address for IN endpoint Tx FIFO is in term of 32-bit words.

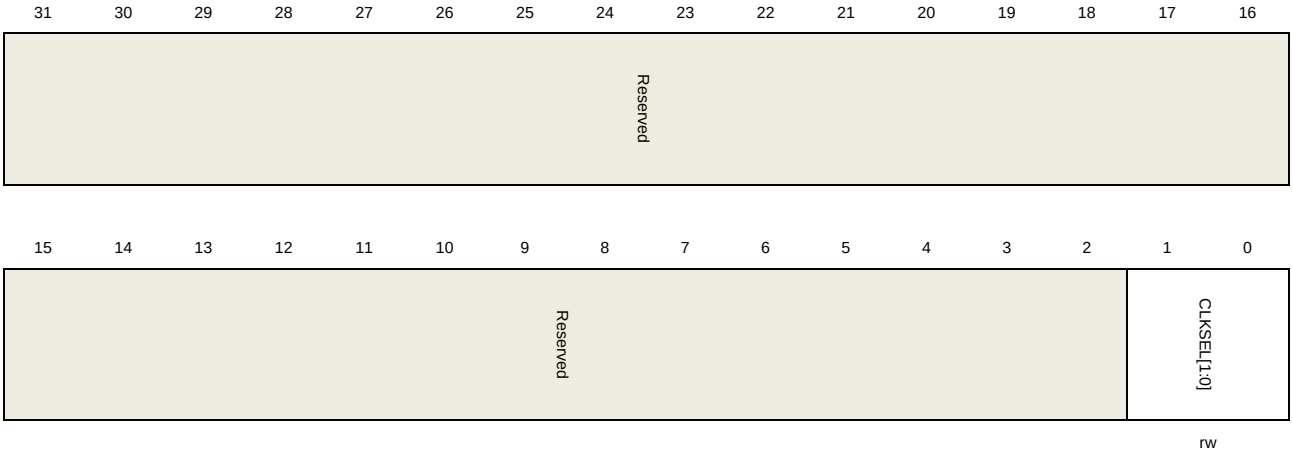
28.7.2. Host control and status registers

Host control register (USBFS_HCTL)

Address offset: 0x0400
Reset value: 0x0000 0000

This register configures the core after power on in host mode. It is not need to modify it after host initialization.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:2	Reserved	Must be kept at reset value.
1:0	CLKSEL[1:0]	Clock select for USB clock 01: 48MHz clock others: reserved

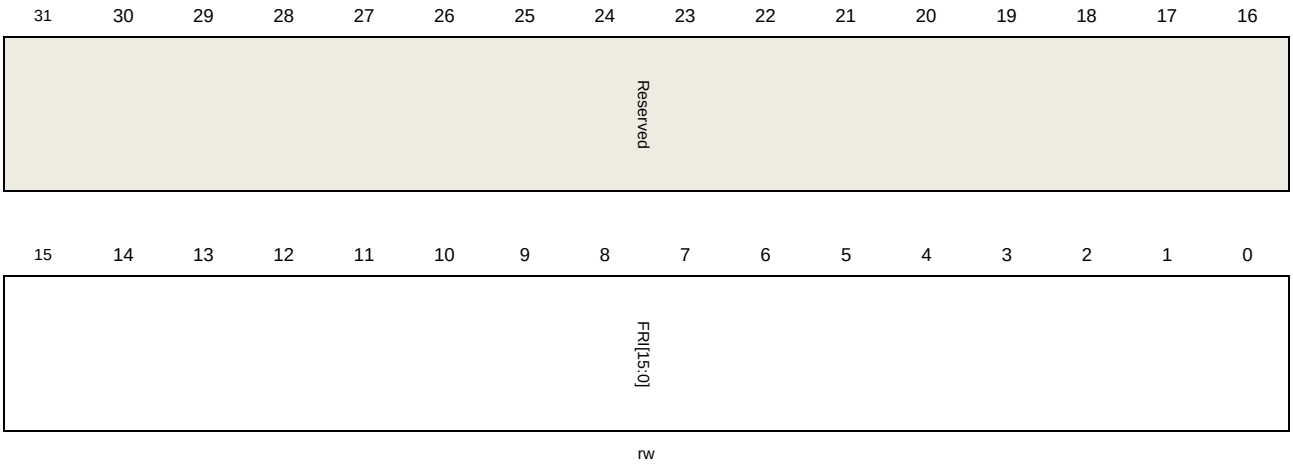
Host frame interval register (USBFS_HFT)

Address offset: 0x0404

Reset value: 0x0000 BB80

This register sets the frame interval when USBFS controller is enumerating USB device.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value.

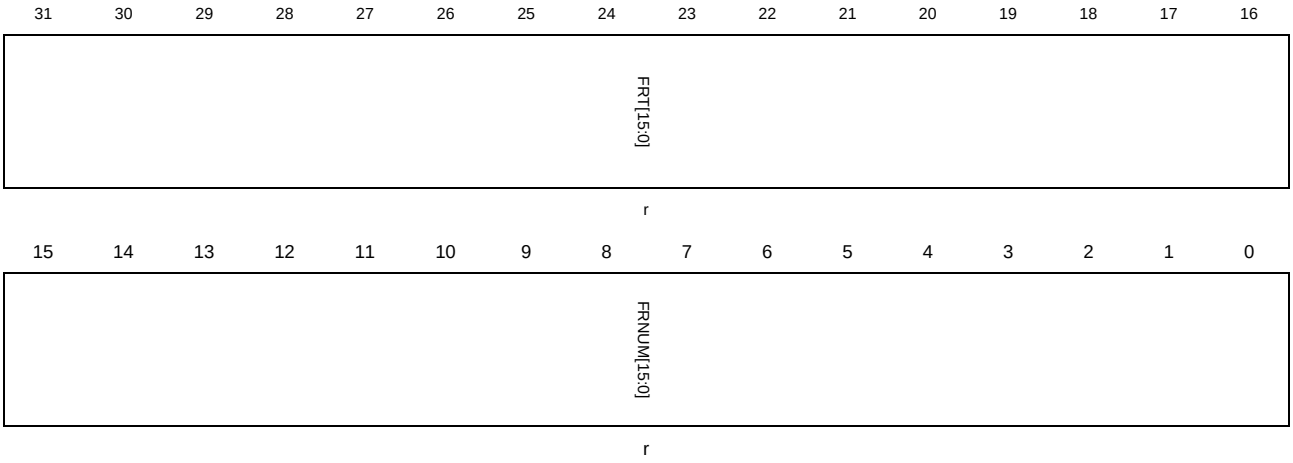
15:0	FRI[15:0]	Frame interval This value describes the frame time in terms of PHY clocks. Each time when port is enabled after a port reset, USBFS uses a proper value according to the current speed, and software can write to this field to change the value. This value should be calculated using the frequency described below: Full-Speed: 48MHz Low-Speed: 6MHz

Host frame information remaining register (USBFS_HFINFR)

Address offset: 0x408

Reset value: 0xBB80 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:16	FRT[15:0]	Frame remaining time This field reports the remaining time of current frame in terms of PHY clocks.
15:0	FRNUM[15:0]	Frame number This field reports the frame number of current frame and returns to 0 after it reaches 0x3FFF.

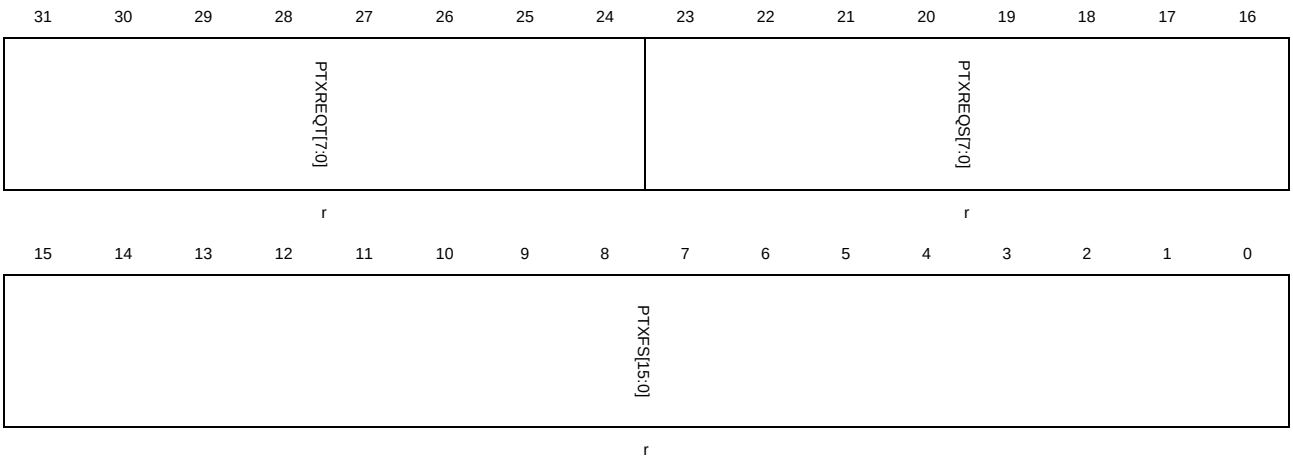
Host periodic Tx FIFO/queue status register (USBFS_HPTFQSTAT)

Address offset: 0x0410

Reset value: 0x0008 0200

This register reports the current status of the host periodic Tx FIFO and request queue. The request queue includes IN, OUT or other request entries in host mode.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:24	PTXREQT[7:0]	Top entry of the periodic Tx request queue Entry in the periodic transmit request queue. Bits 30:27: Channel Number Bits 26:25: 00: IN/OUT token 01: Zero-length OUT packet 11: Channel halt request Bit 24: Terminate Flag, indicating last entry for selected channel.
23:16	PTXREQS[7:0]	Periodic Tx request queue space The remaining space of the periodic transmit request queue. 0: Request queue is Full 1: 1 entry 2: 2 entries … n: n entries (0≤n≤8) Others: Reserved
15:0	PTXFS[15:0]	Periodic Tx FIFO space The remaining space of the periodic Tx FIFO. In terms of 32-bit words. 0: periodic Tx FIFO is full 1: 1 word 2: 2 words n: n words (0≤n≤PTXFD) Others: Reserved

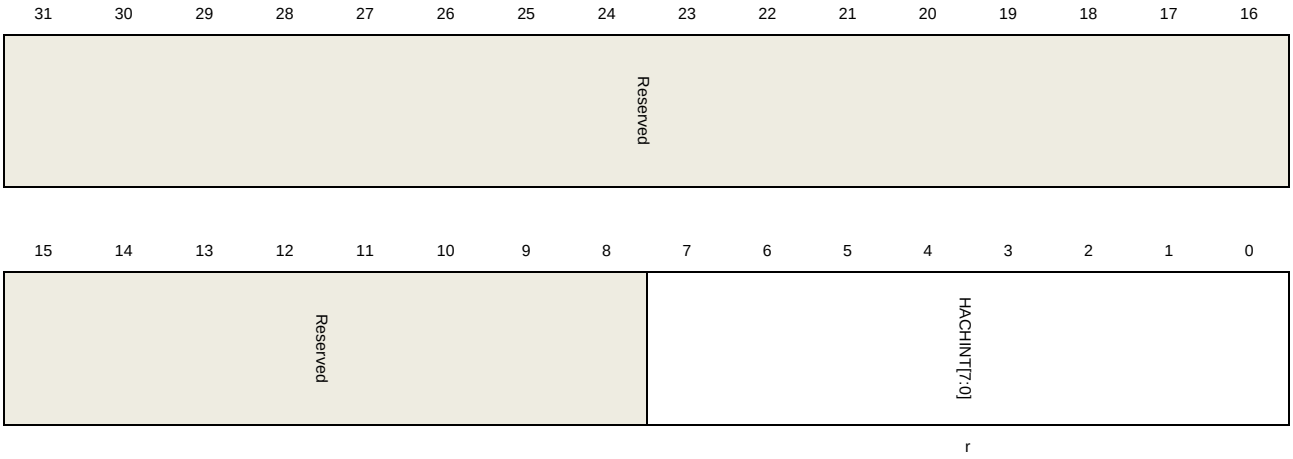
Host all channels interrupt register (USBFS_HACHINT)

Address offset: 0x0414

Reset value: 0x0000 0000

When a channel interrupt is triggered, USBFS sets a corresponding bit in this register and software should read this register to know which channel is asserting interrupts.

This register has to be accessed by word (32-bit)



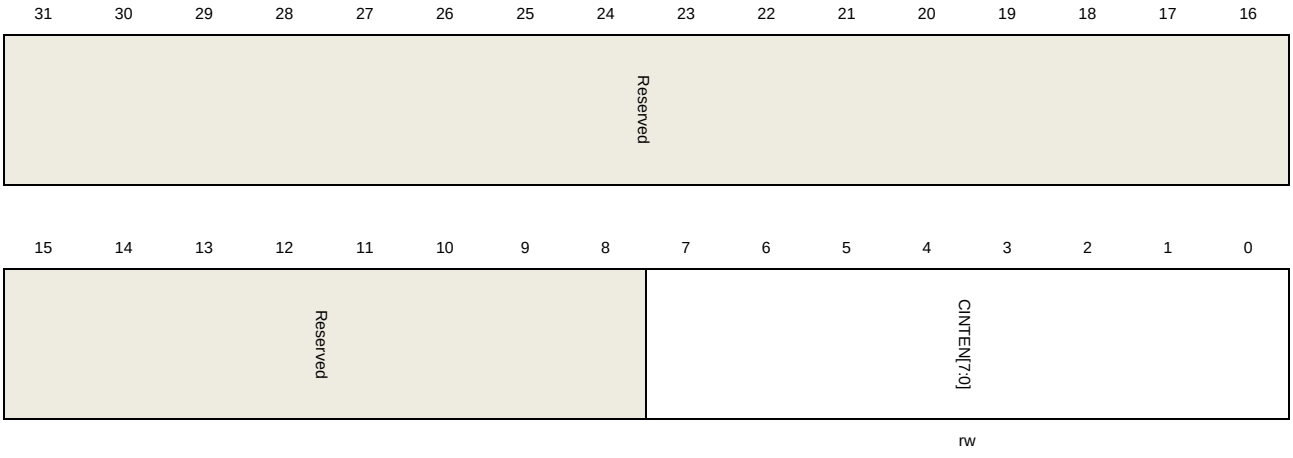
Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value.
7:0	HACHINT[7:0]	Host all channel interrupts Each bit represents a channel: Bit 0 for channel 0, bit 7 for channel 7.

Host all channels interrupt enable register (USBFS_HACHINTEN)

Address offset: 0x0418
Reset value: 0x0000 0000

This register can be used by software to enable or disable a channel's interrupt. Only when the channel whose corresponding bit in this register is set, so as to cause the channel interrupt flag HCIF set in USBFS_GINTF register.

This register has to be accessed by word (32-bit)



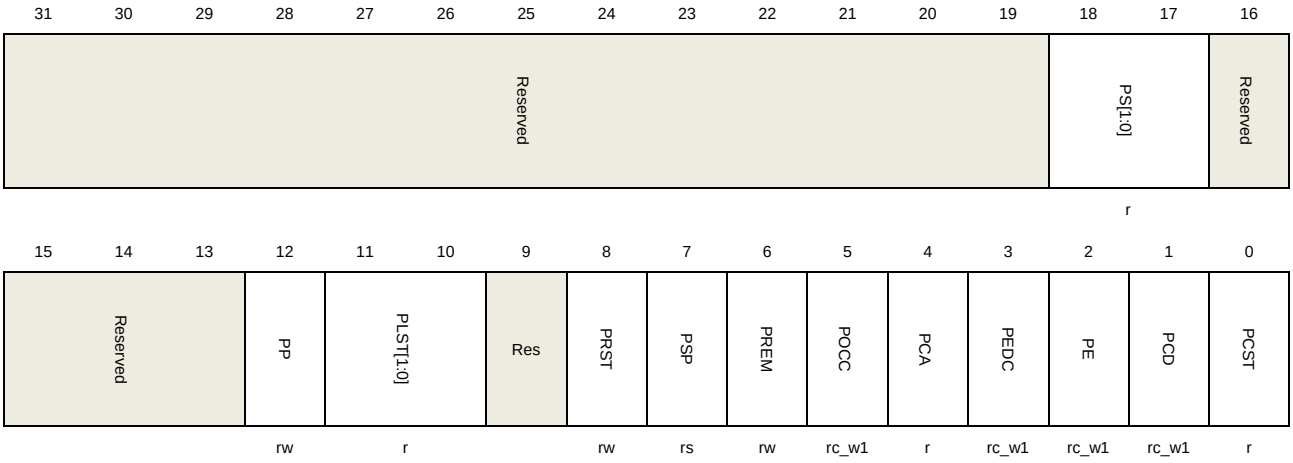
Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value.
7:0	CINTEN[7:0]	Channel interrupt enable 0: Disable channel n interrupt 1: Enable channel n interrupt Each bit represents a channel: Bit 0 for channel 0, bit 7 for channel 7.

Host port control and status register (USBFS_HPCS)

Address offset: 0x0440
Reset value: 0x0000 0000

This register controls the port's behavior and also has some flags which report the status of the port. The HPIF flag in USBFS_GINTF register will be triggered if one of these flags (PRST, PEDC and PCD) in this register is set by USBFS.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:19	Reserved	Must be kept at reset value.
18:17	PS[1:0]	Port speed Report the enumerated speed of the device attached to this port. 01: Full speed 10: Low speed Others: Reserved
16:13	Reserved	Must be kept at reset value.
12	PP	Port power This bit should be set before a port is used. Because USBFS doesn't have power supply ability, it only uses this bit to get whether the port is in powered state. Software should ensure the power supply on VBUS before setting this bit.

		0: Port is powered off 1: Port is powered on
11:10	PLST[1:0]	Port line status Report the current state of USB data lines Bit 10: State of DP line Bit 11: State of DM line
9	Reserved	Must be kept at reset value.
8	PRST	Port reset Application sets this bit to start a reset signal on USB port. Application should clear this bit when it wants to stop the reset signal. 0: Port is not in reset state 1: Port is in reset state
7	PSP	Port suspend Application sets this bit to put port into suspend state. When this bit is set the port stops sending SOF tokens. This bit can only be cleared by the following operations: – PRST in this register is set – PREM bit in this register is set – A remote wakeup signal is detected – A device disconnect is detected 0: Port is not in suspend state 1: Port is in suspend state
6	PREM	Port resume Application sets this bit to start a resume signal on USB port. Application should clear this bit when it wants to stop the resume signal. 0: No resume driven 1: Resume driven
5	POCC	Port over-current change Set by the core when the status of the PCA in this register changes
4	PCA	Port over-current active Indicates the over-current condition of port 0: No over-current condition 1: Over-current condition
3	PEDC	Port enable/disable change Set by the core when the status of the Port enable bit 2 in this register changes.
2	PE	Port Enable This bit is automatically set by USBFS after a USB reset signal finishes and cannot be set by software. This bit is cleared by the following events:

– A disconnection condition
– Software clears this bit

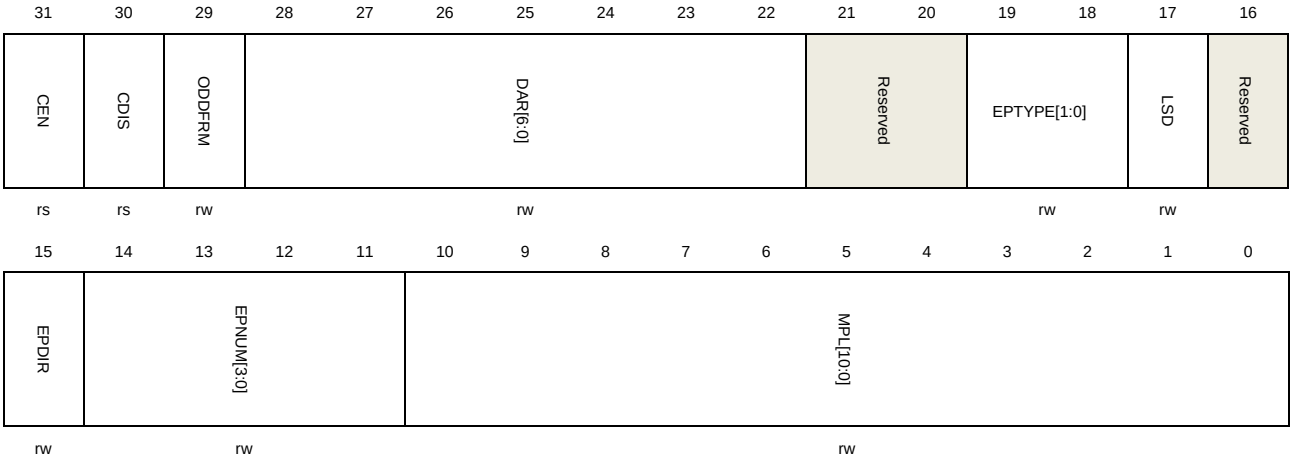
0: Port disabled
1: Port enabled

1	PCD	Port connection detected Set by USBFS when a device connection is detected. This bit can be cleared by writing 1 to this bit.
0	PCST	Port connection status 0: Device is not connected to the port 1: Device is connected to the port

Host channel-x control register (USBFS_HCHxCTL) (x = 0..7 where x = channel_number)

Address offset: 0x0500 + (channel_number × 0x20)
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	CEN	Channel enable Set by the application and cleared by USBFS. 0: Channel disabled 1: Channel enabled Software should following the operation guide to disable or enable a channel.
30	CDIS	Channel disable Software can set this bit to disable the channel from processing transactions. Software should follow the operation guide to disable or enable a channel.
29	ODDFRM	Odd frame

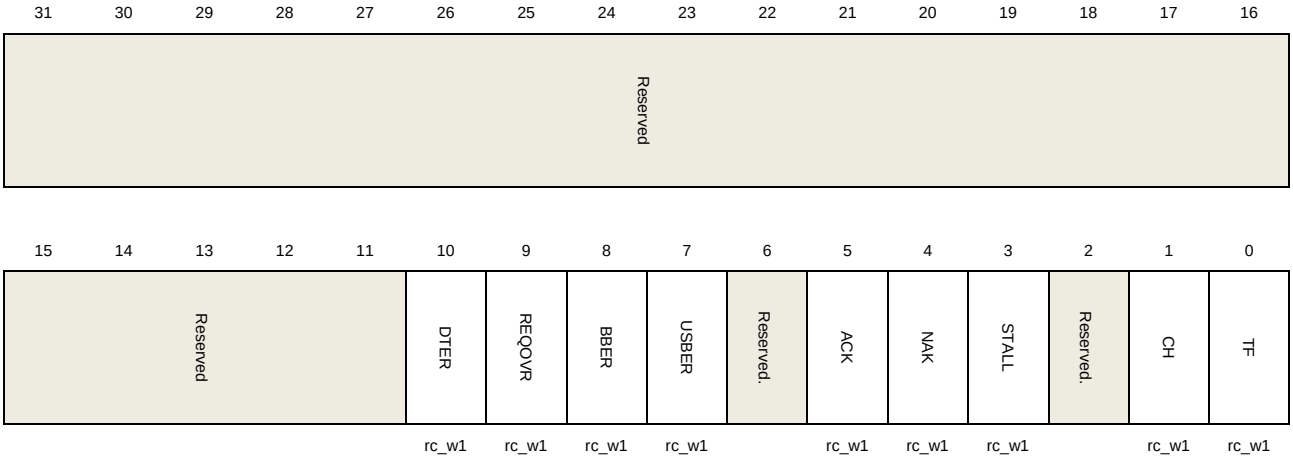
		For periodic transfers (interrupt or isochronous transfer), this bit controls that channel's transaction to be processed is in odd frame or even frame. 0: Even frame 1: Odd frame
28:22	DAR[6:0]	Device address The address of the USB device that this channel wants to communicate with.
21:20	Reserved	Must be kept at reset value.
19:18	EPTYPE[1:0]	Endpoint type The transfer type of the endpoint with which this channel communicates. 00: Control 01: Isochronous 10: Bulk 11: Interrupt
17	LSD	Low-Speed device The device that this channel wants to communicate with is a low-speed device.
16	Reserved	Must be kept at reset value.
15	EPDIR	Endpoint direction The transfer direction of the endpoint that this channel communicates with. 0: OUT 1: IN
14:11	EPNUM[3:0]	Endpoint number The number of the endpoint that this channel communicates with.
10:0	MPL[10:0]	Maximum packet length The target endpoint's maximum packet length.

Host channel-x interrupt flag register (USBFS_HCHxINTF) (x = 0..7 where x = channel number)

Address offset: 0x0508 + (channel_number × 0x20)
Reset value: 0x0000 0000

This register contains the status and events of a channel, when a channel interrupt occurs, application should read this register for the respective channel to get the source of the interrupt. The flag bits in this register are all set by hardware and cleared by writing 1.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:11	Reserved	Must be kept at reset value.
10	DTER	Data toggle error The IN transaction gets a data packet but the PID of this packet doesn't match DPID bits in USBFS_HCHxLEN register.
9	REQOVR	Request queue overrun The periodic request queue is full when software starts new transfers.
8	BBER	Babble error A babble condition occurs on USB bus. A typical reason for babble condition is that a device sends a data packet and the packet length exceeds the endpoint's maximum packet length.
7	USBER	USB Bus Error The USB error flag is set when the following conditions occur during receiving a packet reception: – A received packet has a wrong CRC field – A stuff error detected on USB bus – Timeout when waiting for a response packet
6	Reserved	Must be kept at reset value.
5	ACK	ACK An ACK response is received or transmitted
4	NAK	NAK A NAK response is received.
3	STALL	STALL A STALL response is received.
2	Reserved	Must be kept at reset value.
1	CH	Channel halted

This channel is disabled by a request, and it will not response to other requests during the request processing.

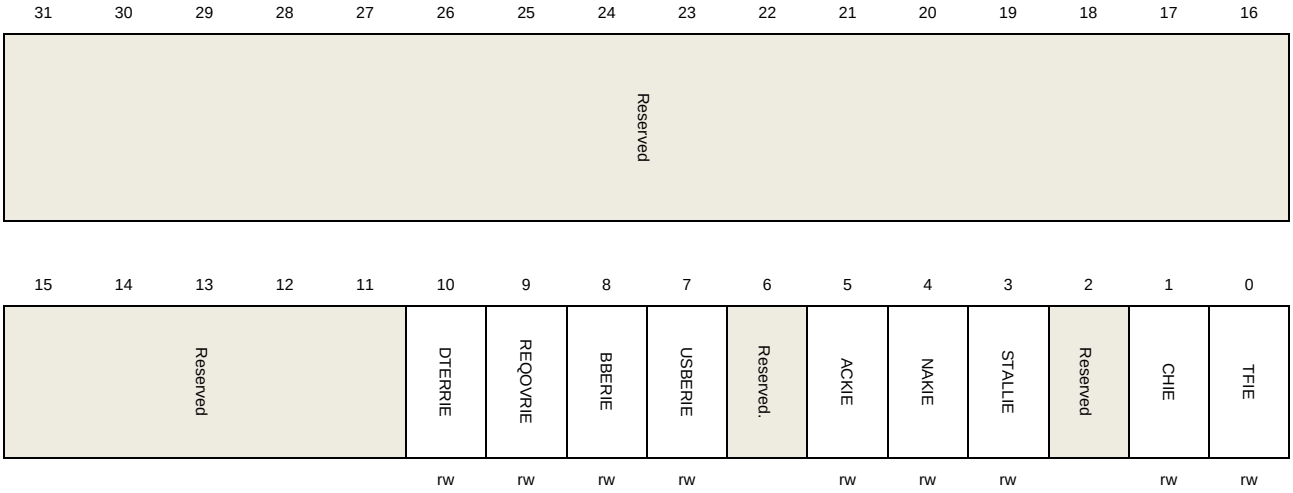
0 TF Transfer finished
All the transactions of this channel finish successfully, and no error occurs. For IN channel, this flag will be triggered after PCNT bits in USBFS_HCHxLEN register reach zero. For OUT channel, this flag will be triggered when software reads and pops a TF status entry from the Rx FIFO.

Host channel-x interrupt enable register (USBFS_HCHxINTEN) (x = 0..7, where x = channel number)

Address offset: 0x050C + (channel_number × 0x20)
Reset value: 0x0000 0000

This register contains the interrupt enable bits for the flags in USBFS_HCHxINTF register. If a bit in this register is set by software, the corresponding bit in USBFS_HCHxINTF register is able to trigger a channel interrupt. The bits in this register are set and cleared by software.

This register has to be accessed by word (32-bit)



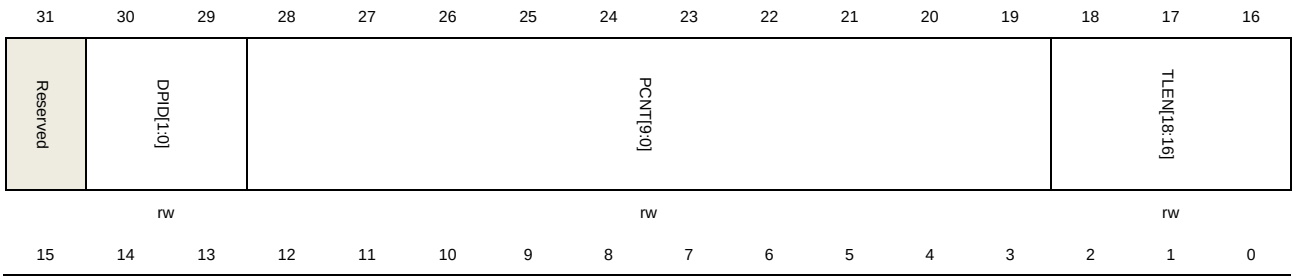
Bits	Fields	Descriptions
31:11	Reserved	Must be kept at reset value.
10	DTERIE	Data toggle error interrupt enable 0: Disable data toggle error interrupt 1: Enable data toggle error interrupt
9	REQOVRIE	Request queue overrun interrupt enable 0: Disable request queue overrun interrupt 1: Enable request queue overrun interrupt
8	BBERIE	Babble error interrupt enable

		0: Disable babble error interrupt 1: Enable babble error interrupt
7	USBERIE	USB bus error interrupt enable 0: Disable USB bus error interrupt 1: Enable USB bus error interrupt
6	Reserved	Must be kept at reset value.
5	ACKIE	ACK interrupt enable 0: Disable ACK interrupt 1: Enable ACK interrupt
4	NAKIE	NAK interrupt enable 0: Disable NAK interrupt 1: Enable NAK interrupt
3	STALLIE	STALL interrupt enable 0: Disable STALL interrupt 1: Enable STALL interrupt
2	Reserved	Must be kept at reset value.
1	CHIE	Channel halted interrupt enable 0: Disable channel halted interrupt 1: Enable channel halted interrupt
0	TFIE	Transfer finished interrupt enable 0: Disable transfer finished interrupt 1: Enable transfer finished interrupt

Host channel-x transfer length register (USBFS_HCHxLEN) (x = 0..7, where x = channel number)

Address offset: 0x0510 + (channel_number × 0x20)
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



TLEN[15:0]
rw

Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30:29	DPID[1:0]	Data PID Software should write this field before the transfer starts. For OUT transfers, this field controls the DATA PID of the first transmitted packet. For IN transfers, this field controls the expected DATA PID of the first received packet, and DTERR will be triggered if the DATA PID doesn't match. After the transfer starts, USBFS changes and toggles this field automatically following the USB protocol. 00: DATA0 10: DATA1 11: SETUP (for control transfer only) 01: Reserved
28:19	PCNT[9:0]	Packet count The number of data packets desired to be transmitted (OUT) or received (IN) in a transfer. Software should program this field before the channel is enabled. After the transfer starts, this field is decreased automatically after each successful data packet transmission.
18:0	TLEN[18:0]	Transfer length The total data bytes number of a transfer. For OUT transfers, this field is the total data bytes of all the data packets desired to be transmitted in an OUT transfer. Software should program this field before the channel is enabled. When software successfully writes a packet into the channel's data Tx FIFO, this field is decreased by the byte size of the packet. For IN transfer each time software or DMA reads out a packet from the RxFIFO, this field is decreased by the byte size of the packet.

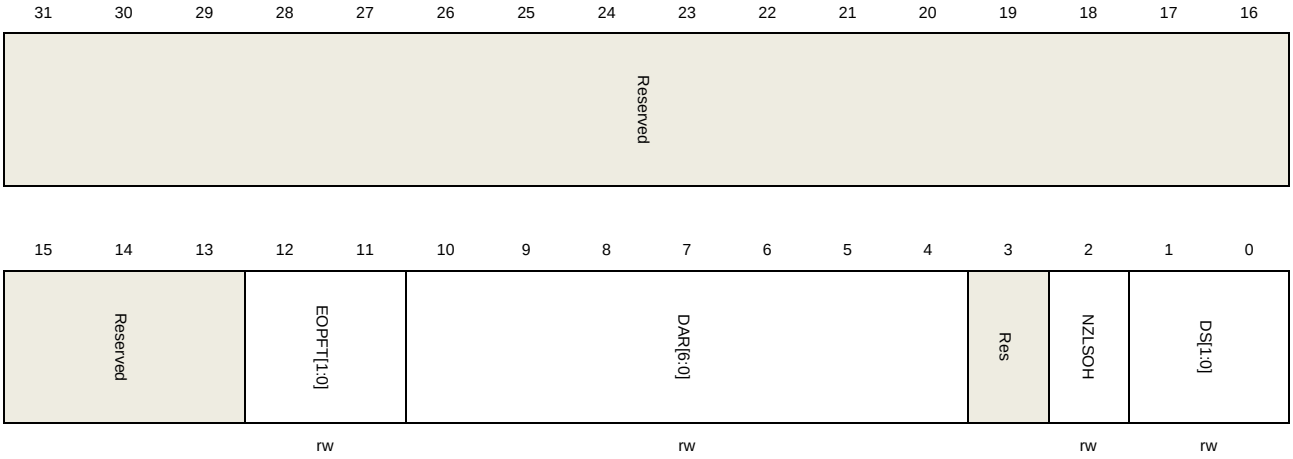
28.7.3. Device control and status registers

Device configuration register (USBFS_DCFG)

Address offset: 0x0800
Reset value: 0x0000 0000

This register configures the core in device mode after power on, certain control commands or enumeration. It is not able to change this register after device initialization.

This register has to be accessed by word (32-bit)



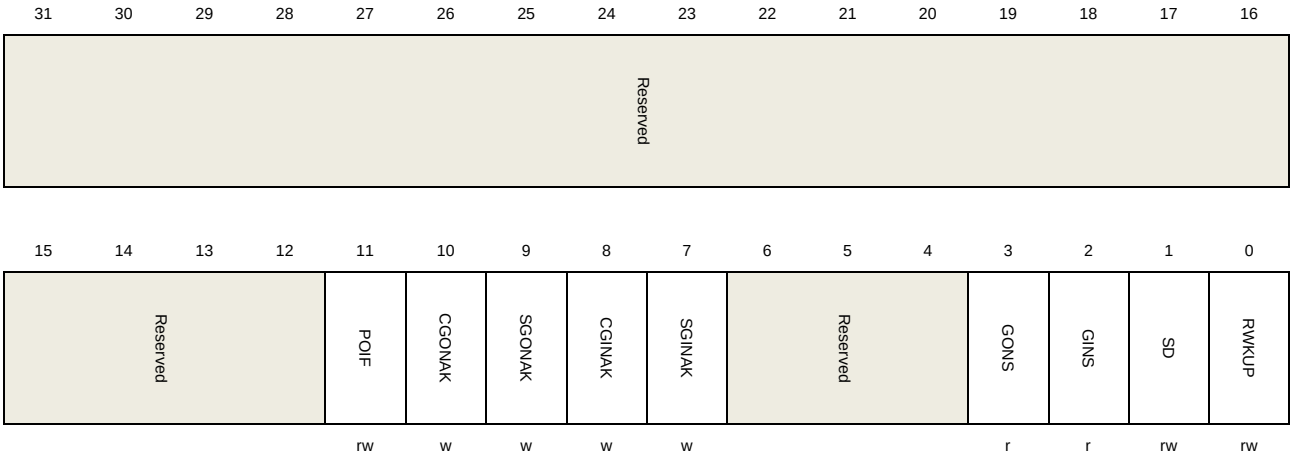
Bits	Fields	Descriptions
31:13	Reserved	Must be kept at reset value.
12:11	EOPFT[1:0]	End of periodic frame time This field defines the percentage time point in a frame that the end of periodic frame (EOPF) flag should be triggered. 00: 80% of the frame time 01: 85% of the frame time 10: 90% of the frame time l 11: 95% of the frame time
10:4	DAR[6:0]	Device address This field defines the USB device address. USBFS uses this field to match with the incoming token's device address field. Software should program this field after receiving a set_address command from USB host.
3	Reserved	Must be kept at reset value.
2	NZLSOH	Non-zero-length status OUT handshake When a USB device receives a non-zero-length data packet during status OUT stage, this field controls that USBFS should either receive this packet or reject this packet with a STALL handshake. 0: Treat this packet as a normal packet and response according to the status of NAKS and STALL bits in USBFS_DOEPxCTL register. 1: Send a STALL handshake and don't save the received OUT packet.
1:0	DS[1:0]	Device speed This field controls the device speed when the device connected to a host. 11: Full speed Others: Reserved

Device control register (USBFS_DCTL)

Address offset: 0x0804

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value.
11	POIF	Power-on initialization finished Software should set this bit to notify USBFS that the registers have been initialized after waking up from power down state.
10	CGONAK	Clear global OUT NAK Software sets this bit to clear GONS bit in this register.
9	SGONAK	Set global OUT NAK Software sets this bit to set GONS bit in this register. When GONS bit is zero, setting this bit will also cause GONAK flag in USBFS_GINTF register triggered after a while. Software should clear the GONAK flag before writing this bit again.
8	CGINAK	Clear global IN NAK Software sets this bit to clear GINS bit in this register.
7	SGINAK	Set global IN NAK Software sets this bit to set GINS bit in this register. When GINS bit is zero, setting this bit will also cause GINAK flag in USBFS_GINTF register triggered after a while. Software should clear the GINAK flag before writing this bit again.
6:4	Reserved	Must be kept at reset value.
3	GONS	Global OUT NAK status 0: The handshake that USBFS responds to OUT transaction packet and whether

		to save the OUT data packet are decided by Rx FIFO status, endpoint's NAK and STALL bits 1: USBFS always responds to OUT transaction with NAK handshake and doesn't save the incoming OUT data packet
2	GINS	Global IN NAK status 0: The response to IN transaction is decided by Tx FIFO status, endpoint's NAK and STALL bits. 1: USBFS always responses to IN transaction with a NAK handshake.
1	SD	Soft disconnect Software can use this bit to generate a soft disconnection condition on USB bus. After this bit is set, USBFS switches off the pull-up resistor on DP line. This will cause the host to detect a device disconnection. 0: No soft disconnect generated. 1: Generate a soft disconnection.
0	RWKUP	Remote wakeup In suspend state, software can use this bit to generate a Remote wake up signal to inform host that it should resume the USB bus. 0: No remote wakeup signal generated. 1: Generate remote wakeup signal.

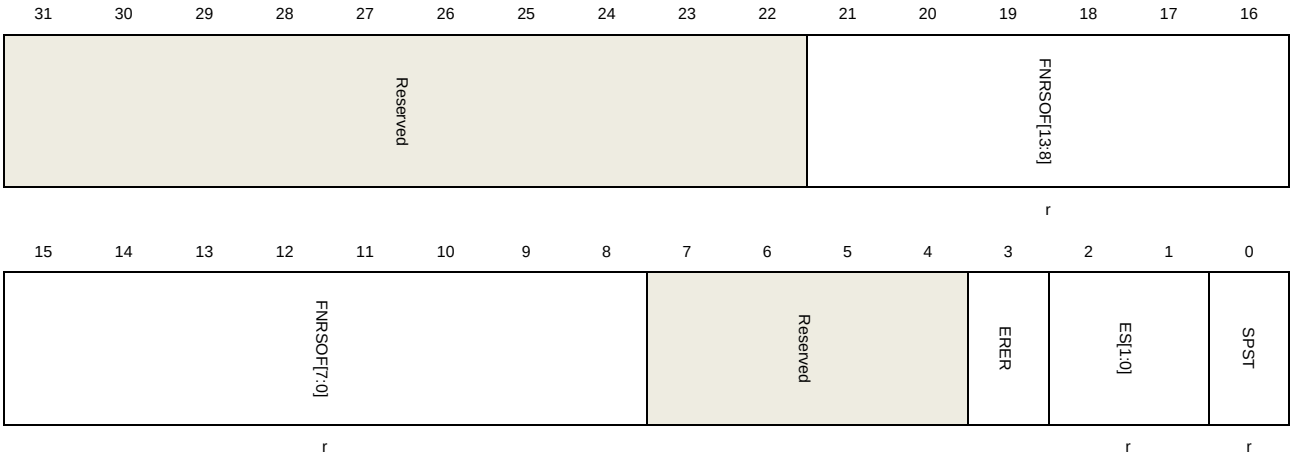
Device status register (USBFS_DSTAT)

Address offset: 0x0808

Reset value: 0x0000 0000

This register contains status and information of the USBFS in device mode.

This register has to be accessed by word (32-bit)



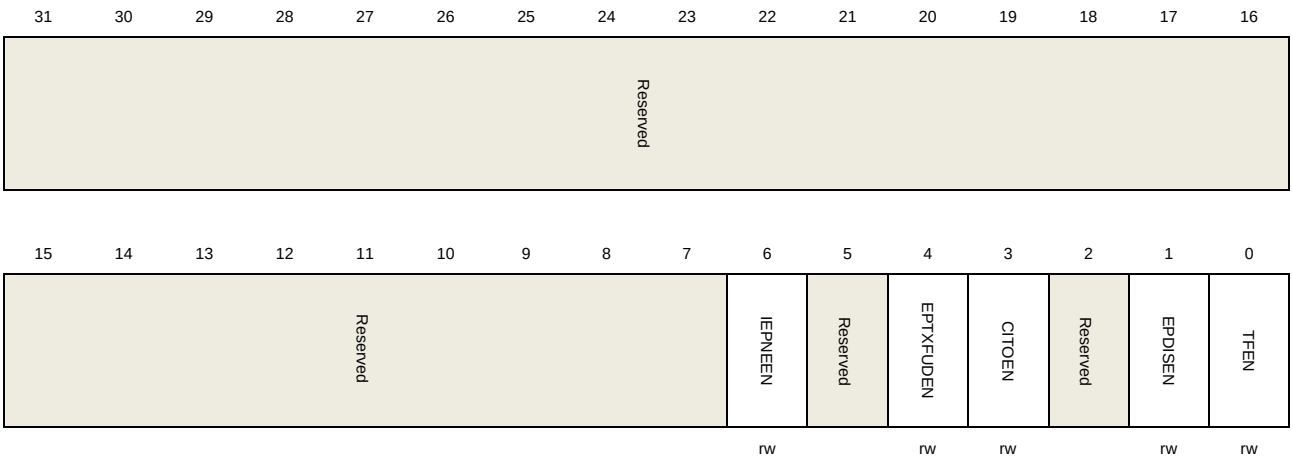
Bits	Fields	Descriptions
31:22	Reserved	Must be kept at reset value.
21:8	FNRSOF[13:0]	The frame number of the received SOF. USBFS always update this field after receiving a SOF token
7:4	Reserved	Must be kept at reset value.
3	ERER	Erratic error, set by the core when erratic errors happen.
2:1	ES[1:0]	Enumerated speed This field reports the enumerated device speed. Read this field after the ENUMF flag in USBFS_GINTF register is triggered. 11: Full speed Others: reserved
0	SPST	Suspend status This bit reports whether device is in suspend state. 0: Device is in suspend state. 1: Device is not in suspend state.

Device IN endpoint common interrupt enable register (USBFS_DIEPINTEN)

Address offset: 0x810
Reset value: 0x0000 0000

This register contains the interrupt enable bits for the flags in USBFS_DIEPxINTF register. If a bit in this register is set by software, the corresponding bit in USBFS_DIEPxINTF register is able to trigger an endpoint interrupt in USBFS_DAEPINT register. The bits in this register are set and cleared by software.

This register has to be accessed by word (32-bit)



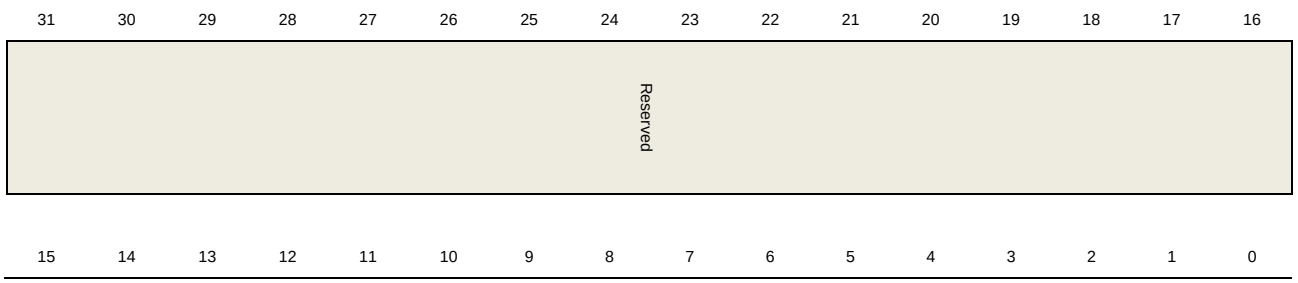
Bits	Fields	Descriptions
31:7	Reserved	Must be kept at reset value.
6	IEPNEEN	IN endpoint NAK effective interrupt enable bit 0: Disable IN endpoint NAK effective interrupt 1: Enable IN endpoint NAK effective interrupt
5	Reserved	Must be kept at reset value.
4	EPTXFUDEN	Endpoint Tx FIFO underrun interrupt enable bit 0: Disable endpoint Tx FIFO underrun interrupt 1: Enable endpoint Tx FIFO underrun interrupt
3	CITOEN	Control IN timeout interrupt enable bit 0: Disable control IN timeout interrupt 1: Enable control IN timeout interrupt
2	Reserved	Must be kept at reset value.
1	EPDISEN	Endpoint disabled interrupt enable bit 0: Disable endpoint disabled interrupt 1: Enable endpoint disabled interrupt
0	TFEN	Transfer finished interrupt enable bit 0: Disable transfer finished interrupt 1: Enable transfer finished interrupt

Device OUT endpoint common interrupt enable register (USBFS_DOEPINTEN)

Address offset: 0x0814
Reset value: 0x0000 0000

This register contains the interrupt enable bits for the USBFS_DOEPxINTF register. If a bit in this register is set by software, the corresponding bit in USBFS_DOEPxINTF register is able to trigger an endpoint interrupt in USBFS_DAEPINT register. The bits in this register are set and cleared by software.

This register has to be accessed by word (32-bit)



Reserved	BTBSTPEN	Reserved	EPRXFOVREN	STPFEN	Reserved	EPDISEN	TFEN
	rw		rw	rw		rw	rw

Bits	Fields	Descriptions
31:7	Reserved	Must be kept at reset value.
6	BTBSTPEN	Back-to-back SETUP packets (only for control OUT endpoint) interrupt enable bit 0: Disable back-to-back SETUP packets interrupt 1: Enable back-to-back SETUP packets interrupt
5	Reserved	Must be kept at reset value.
4	EPRXFOVREN	Endpoint Rx FIFO overrun interrupt enable bit 0: Disable endpoint Rx FIFO overrun interrupt 1: Enable endpoint Rx FIFO overrun interrupt
3	STPFEN	SETUP phase finished (only for control OUT endpoint) interrupt enable bit 0: Disable SETUP phase finished interrupt 1: Enable SETUP phase finished interrupt
2	Reserved	Must be kept at reset value.
1	EPDISEN	Endpoint disabled interrupt enable bit 0: Disable endpoint disabled interrupt 1: Enable endpoint disabled interrupt
0	TFEN	Transfer finished interrupt enable bit 0: Disable transfer finished interrupt 1: Enable transfer finished interrupt

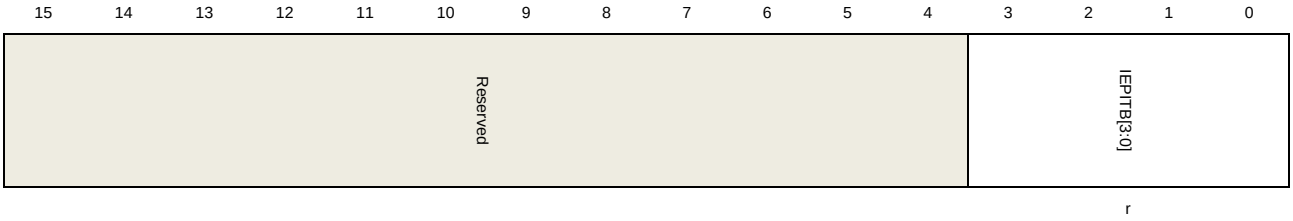
Device all endpoints interrupt register (USBFS_DAEPINT)

Address offset: 0x0818
Reset value: 0x0000 0000

When an endpoint interrupt is triggered, USBFS sets corresponding bit in this register and software should read this register to know which endpoint is asserting an interrupt.

This register has to be accessed by word (32-bit)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved												OEPITB[3:0]			
												r			



Bits	Fields	Descriptions
31:20	Reserved	Must be kept at reset value.
19:16	OEPITB[3:0]	Device all OUT endpoint interrupt bits Each bit represents an OUT endpoint: Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.
15:4	Reserved	Must be kept at reset value
3:0	IEPITB[3:0]	Device all IN endpoint interrupt bits Each bit represents an IN endpoint: Bit 0 for IN endpoint 0, bit 3 for IN endpoint 3.

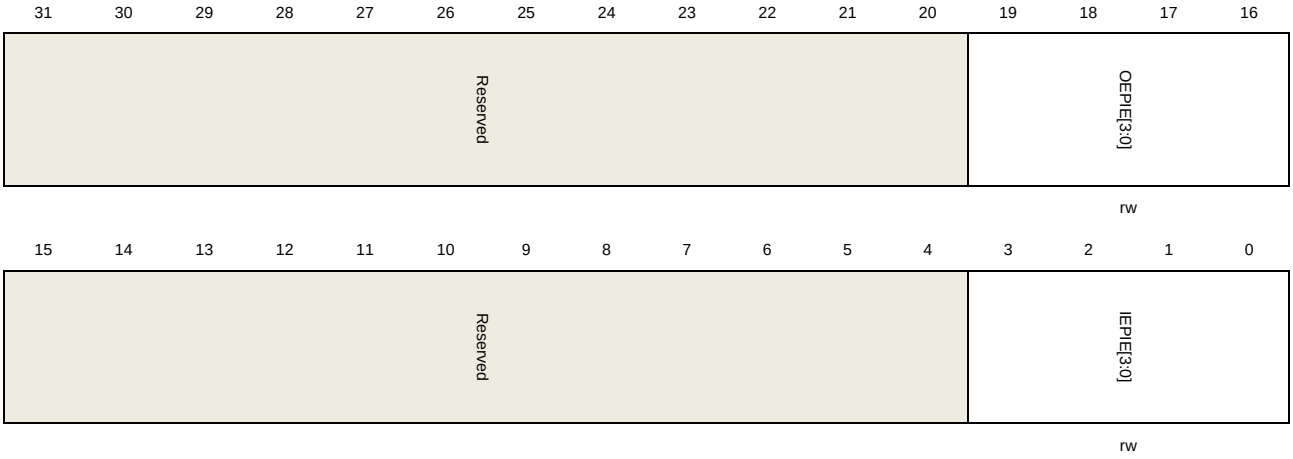
Device all endpoints interrupt enable register (USBFS_DAEPINTEN)

Address offset: 0x081C

Reset value: 0x0000 0000

This register can be used by software to enable or disable an endpoint's interrupt. Only when the endpoint whose corresponding bit in this register is set, it is able to trigger the endpoint interrupt flag OEPIF or IEPIF in USBFS_GINTF register.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:20	Reserved	Must be kept at reset value.

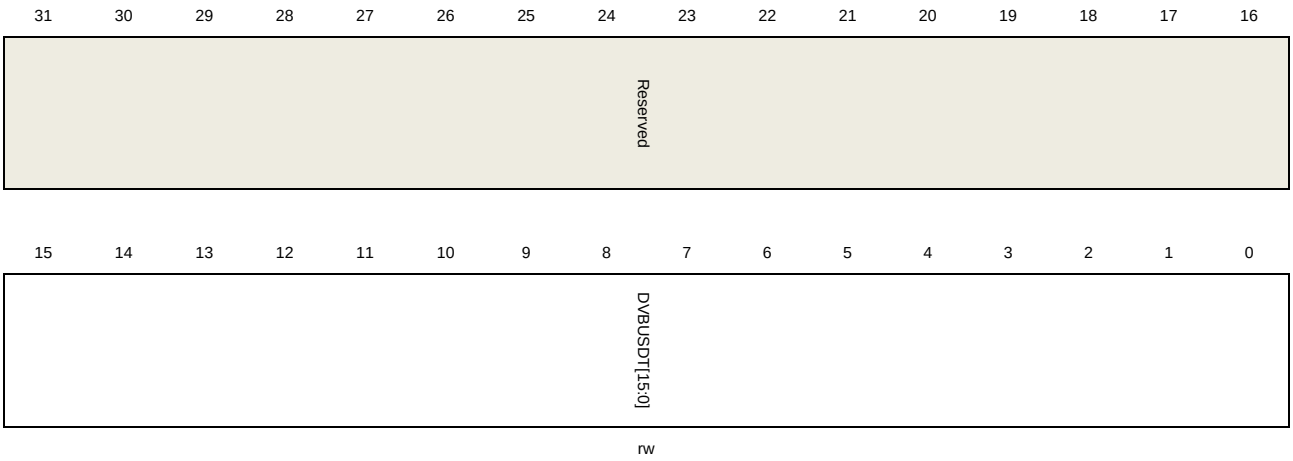
19:16	OEPIE[3:0]	Out endpoint interrupt enable 0: Disable OUT endpoint n interrupt 1: Enable OUT endpoint n interrupt Each bit represents an OUT endpoint: Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.
15:4	Reserved	Must be kept at reset value.
3:0	IEPIE[3:0]	IN endpoint interrupt enable bits 0: Disable IN endpoint n interrupt 1: Enable IN endpoint n interrupt Each bit represents an IN endpoint: Bit 0 for IN endpoint 0, bit 3 for IN endpoint 3.

Device VBUS discharge time register (USBFS_DVBUSDT)

Address offset: 0x0828

Reset value: 0x0000 17D7

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value.
15:0	DVBUSDT[15:0]	Device V_{BUS} discharge time There is a discharge process after V_{BUS} pulsing in SRP protocol. This field defines the discharge time of V_{BUS}. The true discharge time is 1024 * DVBUSDT[15:0] *$T_{USBCLOCK}$, where $T_{USBCLOCK}$ is the period time of USB clock.

Device VBUS pulsing time register (USBFS_DVBUSPT)

Address offset: 0x082C

Reset value: 0x0000 05B8

This register has to be accessed by word (32-bit)

Bits	Fields	Descriptions
31:12	Reserved	Must be kept at reset value.
11:0	DVBUSPT[11:0]	Device V_{BUS} pulsing time This field defines the pulsing time for V_{BUS}. The true pulsing time is 1024*DVBUSPT[11:0] *$T_{USBCLOCK}$, where $T_{USBCLOCK}$ is the period time of USB clock.

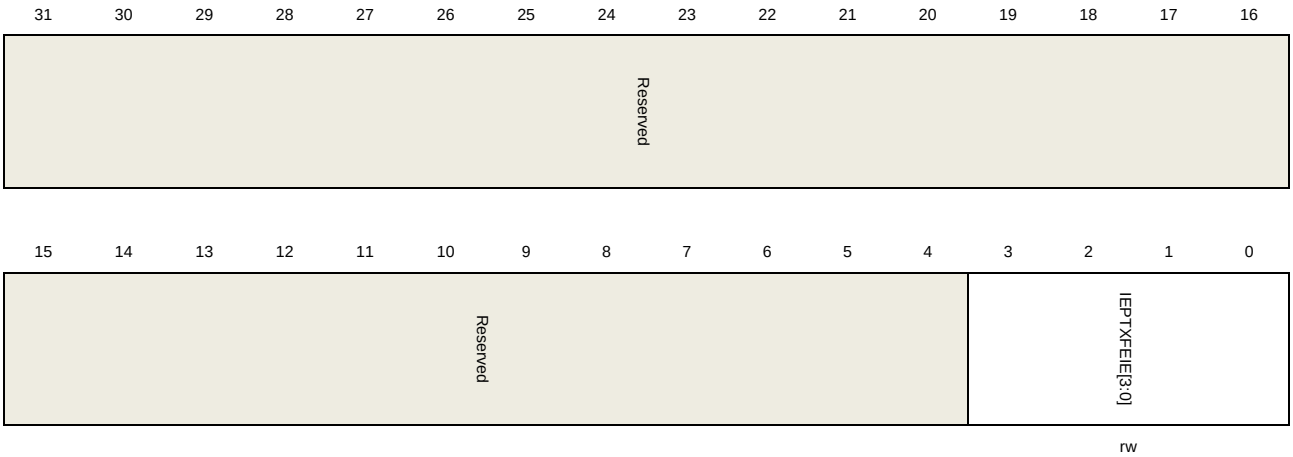
Device IN endpoint FIFO empty interrupt enable register (USBFS_DIEPFEINTEN)

Address offset: 0x0834

Reset value: 0x0000 0000

This register contains the enable bits for the Tx FIFO empty interrupts of IN endpoints.

This register has to be accessed by word (32-bit)



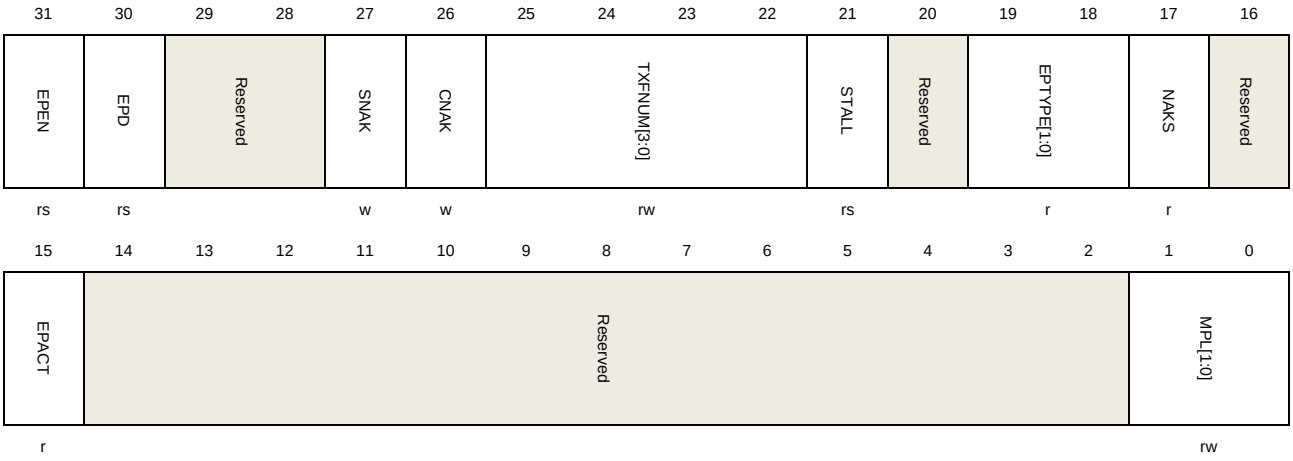
Bits	Fields	Descriptions
31:4	Reserved	Must be kept at reset value.
3:0	IEPTXFEIE[3:0]	IN endpoint Tx FIFO empty interrupt enable bits This field controls whether the TXFE bits in USBFS_DIEPxINTF registers are able to generate an endpoint interrupt bit in USBFS_DAEPINT register. Bit 0 for IN endpoint 0, bit 3 for IN endpoint 3 0: Disable FIFO empty interrupt 1: Enable FIFO empty interrupt

Device IN endpoint 0 control register (USBFS_DIEP0CTL)

Address offset: 0x0900

Reset value: 0x0000 8000

This register has to be accessed by word (32-bit)



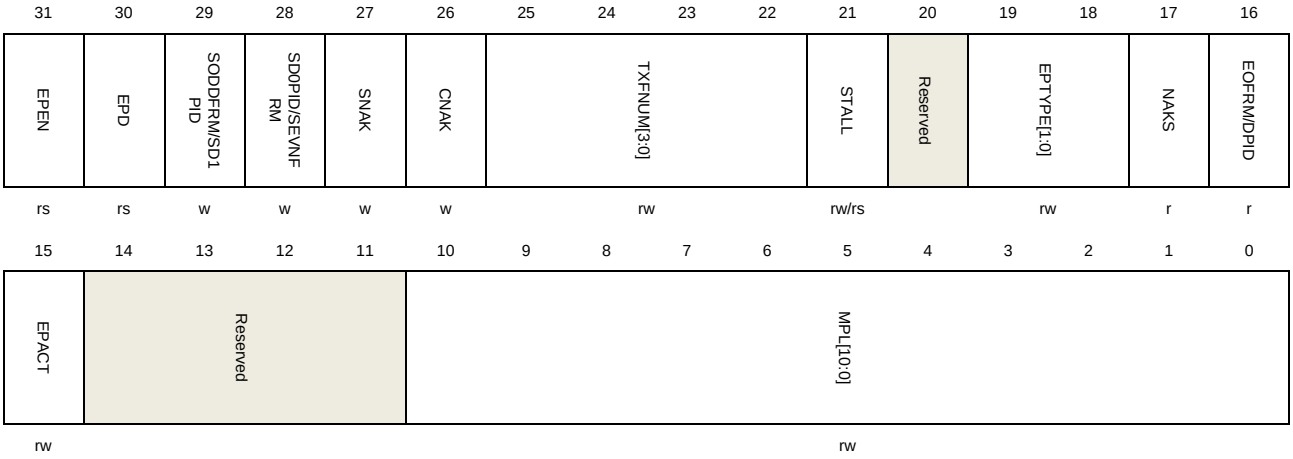
Bits	Fields	Descriptions
31	EPEN	Endpoint enable Set by the application and cleared by USBFS. 0: Endpoint disabled 1: Endpoint enabled Software should follow the operation guide to disable or enable an endpoint.
30	EPD	Endpoint disable Software can set this bit to disable the endpoint. Software should follow the operation guide to disable or enable an endpoint.
29:28	Reserved	Must be kept at reset value.
27	SNAK	Set NAK Software sets this bit to set NAKS bit in this register.
26	CNAK	Clear NAK

		Software sets this bit to clear NAKS bit in this register.
25:22	TXFNUM[3:0]	Tx FIFO number Define the Tx FIFO number of IN endpoint 0.
21	STALL	STALL handshake Software can set this bit to send STALL handshake when receiving IN token. USBFS will clear this bit after a SETUP token is received on the corresponding OUT endpoint 0. This bit has a higher priority than NAKS bit in this register and GINS bit in USBFS_DCTL register. If both STALL and NAKS bits are set, the STALL bit takes effect.
20	Reserved	Must be kept at reset value.
19:18	EPTYPE[1:0]	Endpoint type This field is fixed to '00' for control endpoint.
17	NAKS	NAK status This bit controls the NAK status of USBFS when both STALL bit in this register and GINS bit in USBFS_DCTL register are cleared: 0: USBFS sends data or handshake packets according to the status of the endpoint's Tx FIFO. 1: USBFS always sends NAK handshake to the IN token. This bit is read-only and software should use CNAK and SNAK in this register to control this bit.
16	Reserved	Must be kept at reset value.
15	EPACT	Endpoint active This field is fixed to '1' for endpoint 0.
14:2	Reserved	Must be kept at reset value.
1:0	MPL[1:0]	Maximum packet length This field defines the maximum packet length for a control data packet. As described in USB 2.0 protocol, there are 4 kinds of length for control transfers: 00: 64 bytes 01: 32 bytes 10: 16 bytes 11: 8 bytes

Device IN endpoint-x control register (USBFS_DIEPxCTL) (x = 1..3, where x = endpoint_number)

Address offset: 0x0900 + (endpoint_number × 0x20)
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	EPEN	Endpoint enable Set by the application and cleared by USBFS. 0: Endpoint disabled 1: Endpoint enabled Software should follow the operation guide to disable or enable an endpoint.
30	EPD	Endpoint disable Software can set this bit to disable the endpoint. Software should follow the operation guide to disable or enable an endpoint.
29	SODDFRM	Set odd frame (For isochronous IN endpoints) This bit has effect only if this is an isochronous IN endpoint. Software sets this bit to set EOFRM bit in this register.
	SD1PID	Set DATA1 PID (For interrupt/bulk IN endpoints) Software sets this bit to set DPID bit in this register.
28	SEVENFRM	Set even frame (For isochronous IN endpoints) Software sets this bit to clear EOFRM bit in this register.
	SD0PID	Set DATA0 PID (For interrupt/bulk IN endpoints) Software sets this bit to clear DPID bit in this register.
27	SNAK	Set NAK Software sets this bit to set NAKS bit in this register.
26	CNAK	Clear NAK Software sets this bit to clear NAKS bit in this register.
25:22	TXFNUM[3:0]	Tx FIFO number Defines the Tx FIFO number of this IN endpoint.
21	STALL	STALL handshake Software can set this bit to send STALL handshake when receiving IN token. This

		bit has a higher priority than NAKS bit in this register and GINS bit in USBFS_DCTL register. If both STALL and NAKS bits are set, the STALL bit takes effect. For control IN endpoint: Only USBFS can clear this bit when a SETUP token is received on the corresponding OUT endpoint. Software is not able to clear it. For interrupt or bulk IN endpoint: Only software can clear this bit
20	Reserved	Must be kept at reset value.
19:18	EPTYPE[1:0]	Endpoint type This field defines the transfer type of this endpoint: 00: Control 01: Isochronous 10: Bulk 11: Interrupt
17	NAKS	NAK status This bit controls the NAK status of USBFS when both STALL bit in this register and GINS bit in USBFS_DCTL register are are cleared: 0: USBFS sends data or handshake packets according to the status of the endpoint's Tx FIFO. 1: USBFS always sends NAK handshake to the IN token. This bit is read-only and software should use CNAK and SNAK in this register to control this bit.
16	EOFRM	Even/odd frame (For isochronous IN endpoints) For isochronous transfers, software can use this bit to control that USBFS only sends data packets for IN tokens in even or odd frames. If the parity of the current frame number doesn't match with this bit, USBFS only responds with a zero-length packet. 0: Only sends data in even frames 1: Only sends data in odd frames
	DPID	Endpoint DATA PID (for interrupt/bulk IN endpoints) There is a DATA PID toggle scheme in interrupt or bulk transfer. Set SD0PID to set this bit before a transfer starts and USBFS maintains this bit during transfers according to the data toggle scheme described in USB protocol. 0: Data packet's PID is DATA0 1: Data packet's PID is DATA1
15	EPACT	Endpoint active This bit controls whether this endpoint is active. If an endpoint is not active, it ignores all tokens and doesn't make any response.
14:11	Reserved	Must be kept at reset value.

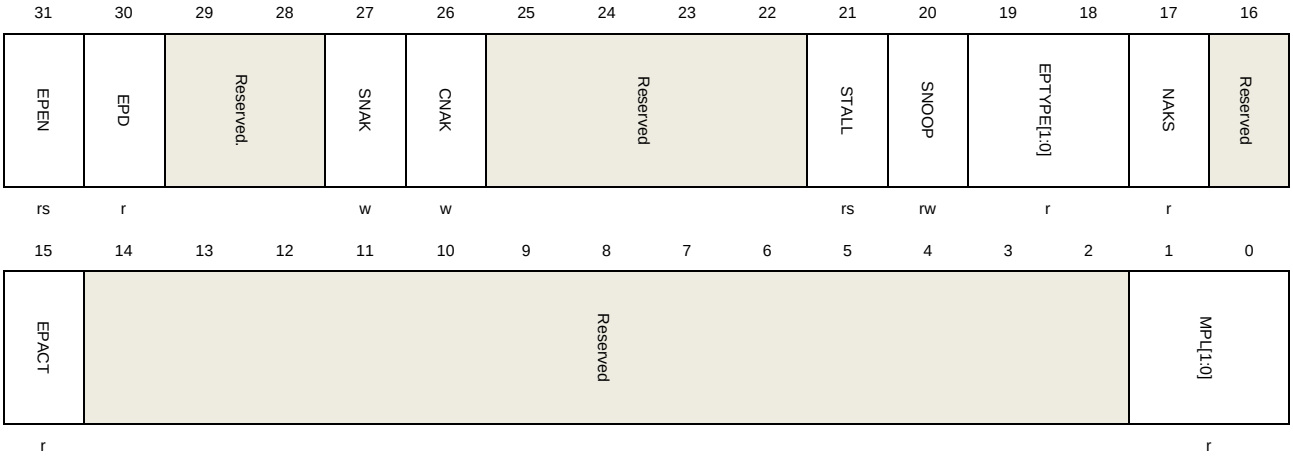
10:0	MPL[10:0]	This field defines the maximum packet length in byte.

Device OUT endpoint 0 control register (USBFS_DOEP0CTL)

Address offset: 0x0B00

Reset value: 0x0000 8000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	EPEN	Endpoint enable Set by the application and cleared by USBFS. 0: Endpoint disabled 1: Endpoint enabled Software should follow the operation guide to disable or enable an endpoint.
30	EPD	Endpoint disable This bit is fixed to 0 for OUT endpoint 0.
29:28	Reserved	Must be kept at reset value.
27	SNAK	Set NAK Software sets this bit to set NAKS bit in this register.
26	CNAK	Clear NAK Software sets this bit to clear NAKS bit in this register
25:22	Reserved	Must be kept at reset value.
21	STALL	STALL handshake Set this bit to send STALL handshake during an OUT transaction. USBFS will clear this bit after a SETUP token is received on OUT endpoint 0. This bit has a higher priority than NAKS bit in this register, i.e. if both STALL and NAKS bits are set, the STALL bit takes effect.

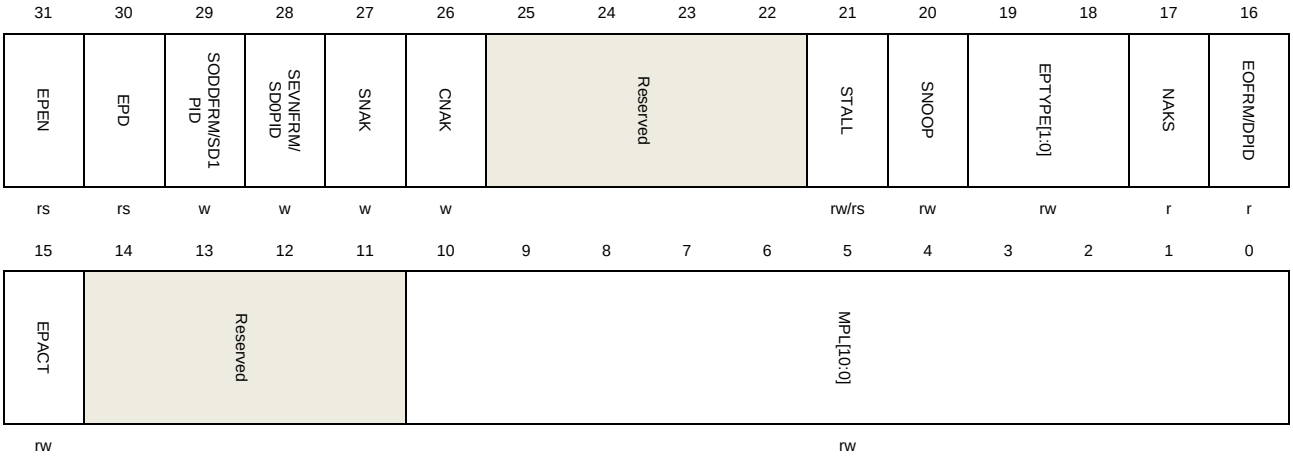
20	SNOOP	Snoop mode This bit controls the snoop mode of an OUT endpoint. In snoop mode, USBFS doesn't check the received data packet's CRC value. 0:Snoop mode disabled 1:Snoop mode enabled
19:18	EPTYPE[1:0]	Endpoint type This field is fixed to '00' for control endpoint.
17	NAKS	NAK status This bit controls the NAK status of USBFS when both STALL bit in this register and GONS bit in USBFS_DCTL register are cleared: 0: USBFS sends data or handshake packets according to the status of the endpoint's Rx FIFO. 1: USBFS always sends NAK handshake for the OUT token. This bit is read-only and software should use CNAK and SNAK in this register to control this bit.
16	Reserved	Must be kept at reset value.
15	EPACT	Endpoint active This field is fixed to '1' for endpoint 0.
14:2	Reserved	Must be kept at reset value.
1:0	MPL[1:0]	Maximum packet length This is a read-only field, and its value comes from the MPL field of USBFS_DIEP0CTL register: 00: 64 bytes 01: 32 bytes 10: 16 bytes 11: 8 bytes

Device OUT endpoint-x control register (USBFS_DOEPxCTL) (x = 1..3, where x = endpoint_number)

Address offset: 0x0B00 + (endpoint_number × 0x20)
Reset value: 0x0000 0000

The application uses this register to control the operations of each logical OUT endpoint other than OUT endpoint 0.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	EPEN	Endpoint enable Set by the application and cleared by USBFS. 0: Endpoint disabled 1: Endpoint enabled Software should follow the operation guide to disable or enable an endpoint.
30	EPD	Endpoint disable Software can set this bit to disable the endpoint. Software should follow the operation guide to disable or enable an endpoint.
29	SODDFRM	Set odd frame (For isochronous OUT endpoints) This bit has effect only if this is an isochronous OUT endpoint. Software sets this bit to set EOFRM bit in this register.
	SD1PID	Set DATA1 PID (For interrupt/bulk OUT endpoints) Software sets this bit to set DPID bit in this register.
28	SEVENFRM	Set even frame (For isochronous OUT endpoints) Software sets this bit to clear EOFRM bit in this register.
	SD0PID	Set DATA0 PID (For interrupt/bulk OUT endpoints) Software sets this bit to clear DPID bit in this register.
27	SNAK	Set NAK Software sets this bit to set NAKS bit in this register.
26	CNAK	Clear NAK Software sets this bit to clear NAKS bit in this register.
25:22	Reserved	Must be kept at reset value.
21	STALL	STALL handshake Software can set this bit to make USBFS sends STALL handshake during an OUT transaction. This bit has a higher priority than NAKS bit in this register and GINAK

		in USBFS_DCTL register. If both STALL and NAKS bits are set, the STALL bit takes effect. For control OUT endpoint: Only USBFS can clear this bit when a SETUP token is received on the corresponding OUT endpoint. Software is not able to clear it. For interrupt or bulk OUT endpoint: Only software can clear this bit.
20	SNOOP	Snoop mode This bit controls the snoop mode of an OUT endpoint. In snoop mode, USBFS doesn't check the received data packet's CRC value. 0:Snoop mode disabled 1:Snoop mode enabled
19:18	EPTYPE[1:0]	Endpoint type This field defines the transfer type of this endpoint: 00: Control 01: Isochronous 10: Bulk 11: Interrupt
17	NAKS	NAK status This bit controls the NAK status of USBFS when both STALL bit in this register and GONS bit in USBFS_DCTL register are cleared: 0: USBFS sends handshake packets according to the status of the endpoint's Rx FIFO. 1: USBFS always sends NAK handshake to the OUT token. This bit is read-only and software should use CNAK and SNAK in this register to control this bit.
16	EOFRM	Even/odd frame (for isochronous OUT endpoints) For isochronous transfers, software can use this bit to control that USBFS only receives data packets in even or odd frames. If the current frame number's parity doesn't match with this bit, USBFS just drops the data packet. 0: Only sends data in even frames 1: Only sends data in odd frames
	DPID	Endpoint data PID (for interrupt/bulk OUT endpoints) These is a data PID toggle scheme in interrupt or bulk transfer. Software should set SD0PID to set this bit before a transfer starts and USBFS maintains this bit during transfers following the data toggle scheme described in USB protocol. 0: Data packet's PID is DATA0 1: Data packet's PID is DATA1
15	EPACT	Endpoint active This bit controls whether this endpoint is active. If an endpoint is not active, it

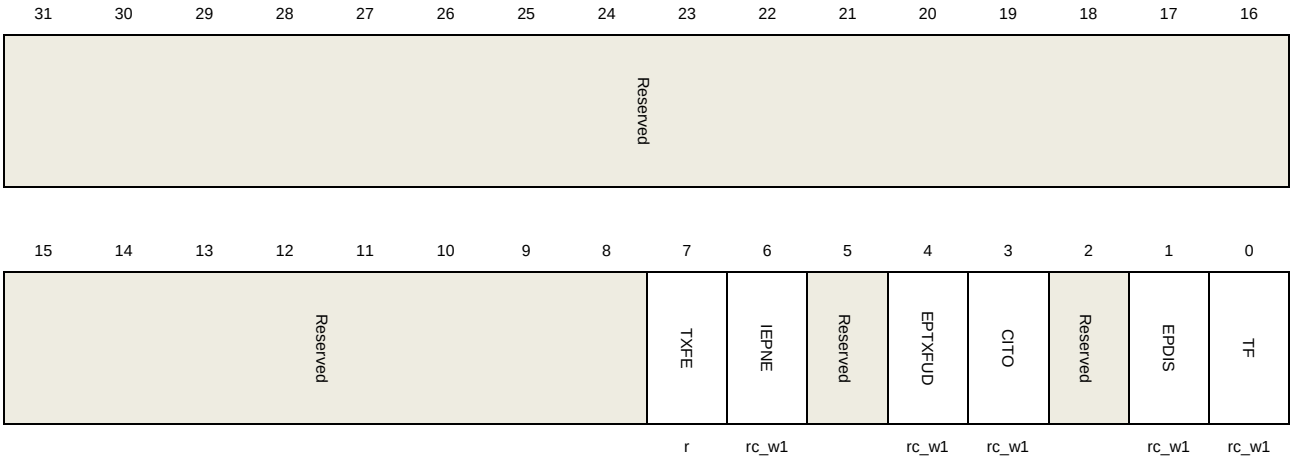
		ignores all tokens and doesn't make any response.
14:11	Reserved	Must be kept at reset value.
10:0	MPL[10:0]	This field defines the maximum packet length in bytes.

Device IN endpoint x interrupt flag register (USBFS_DIEPxINTF) (x = 0..3, where x = endpoint_number)

Address offset: 0x0908 + (endpoint_number × 0x20)
Reset value: 0x0000 0080

This register contains the status and events of an IN endpoint, when an IN endpoint interrupt occurs, read this register for the respective endpoint to get the source of the interrupt. The flag bits in this register are all set by hardware and cleared by writing 1 except the read-only TXFE bit.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:8	Reserved	Must be kept at reset value.
7	TXFE	Tx FIFO empty The Tx FIFO of this IN endpoint has reached the empty threshold value defined by TXFTH field in USBFS_GAHBCS register.
6	IEPNE	IN endpoint NAK effective The setting of SNAK bit in USBFS_DIEPxCTL register takes effect. This bit can be cleared either by writing 1 to it or by setting CNAK bit in USBFS_DIEPxCTL register.
5	Reserved	Must be kept at reset value.
4	EPTXFUD	Endpoint Tx FIFO underrun This flag is triggered if the Tx FIFO has no packet data to send when an IN token

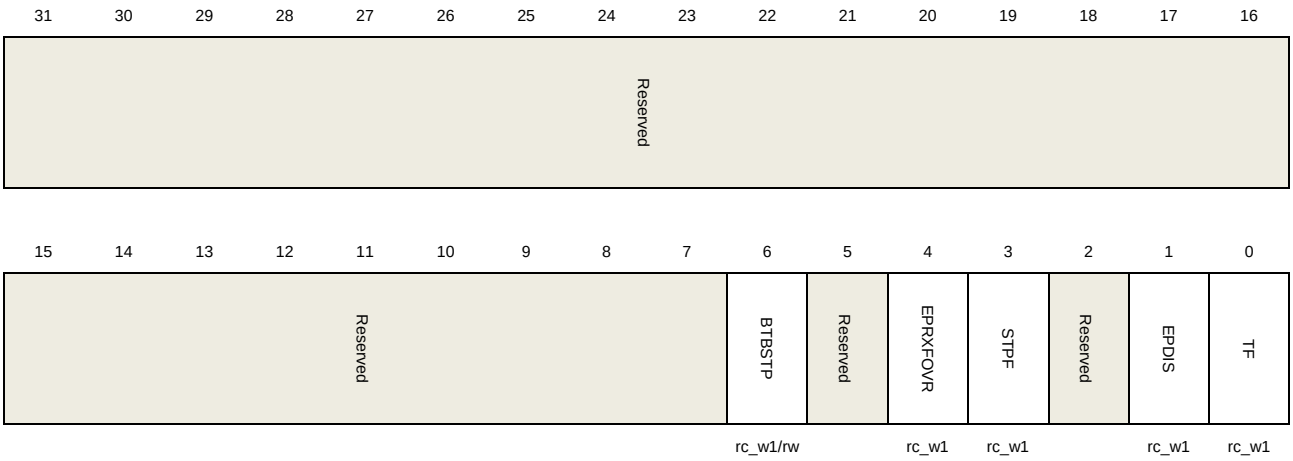
		is received.
3	CITO	Control IN Timeout interrupt This flag is triggered if the device waiting for a handshake is timeout in a control IN transaction.
2	Reserved	Must be kept at reset value.
1	EPDIS	Endpoint disabled This flag is triggered when an endpoint is disabled by the software's request.
0	TF	Transfer finished This flag is triggered when all the IN transactions assigned to this endpoint have been finished.

Device OUT endpoint-x interrupt flag register (USBFS_DOEPxINTF) (x = 0..3, where x = endpoint_number)

Address offset: 0x0B08 + (endpoint_number × 0x20)
Reset value: 0x0000 0000

This register contains the status and events of an OUT endpoint, when an OUT endpoint interrupt occurs, read this register for the respective endpoint to get the source of the interrupt. The flag bits in this register are all set by hardware and cleared by writing 1.

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:7	Reserved	Must be kept at reset value.
6	BTBSTP	Back-to-back SETUP packets (Only for control OUT endpoint) This flag is triggered when a control out endpoint has received more than 3 back-to-back setup packets.
5	Reserved	Must be kept at reset value.

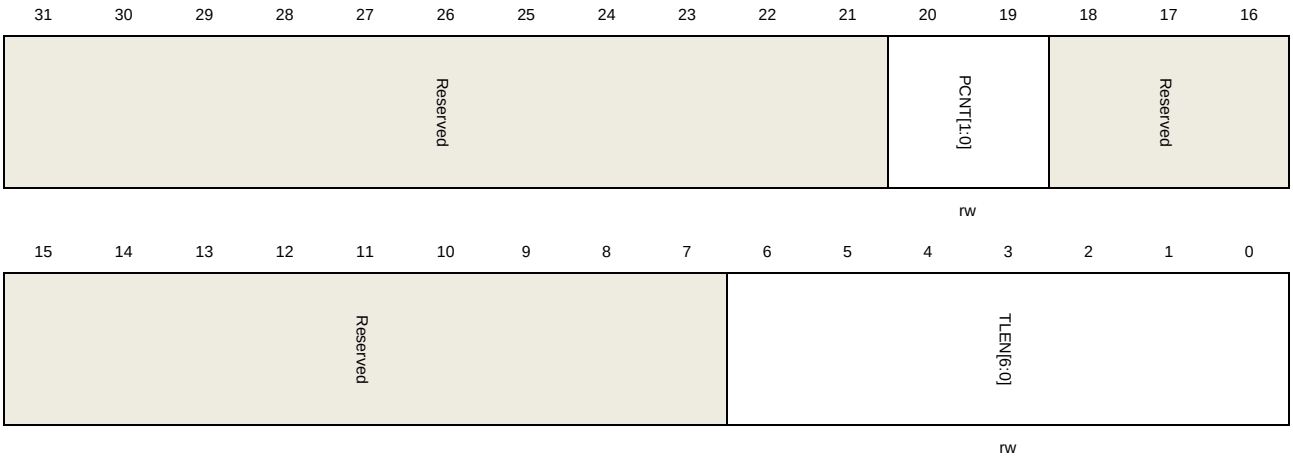
4	EPRXFOVR	Endpoint Rx FIFO overrun This flag is triggered if the OUT endpoint's Rx FIFO has no enough space for a packet data when an OUT token is incoming. USBFS will drop the incoming OUT data packet and sends a NAK handshake in this case.
3	STPF	SETUP phase finished (Only for control OUT endpoint) This flag is triggered when a setup phase finished, i.e. USBFS receives an IN or OUT token after a setup token.
2	Reserved	Must be kept at reset value.
1	EPDIS	Endpoint disabled This flag is triggered when an endpoint is disabled by the software's request.
0	TF	Transfer finished This flag is triggered when all the OUT transactions assigned to this endpoint have been finished.

Device IN endpoint 0 transfer length register (USBFS_DIEP0LEN)

Address offset: 0x0910

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:21	Reserved	Must be kept at reset value.
20:19	PCNT[1:0]	Packet count The number of data packets desired to be transmitted in a transfer. Program this field before the endpoint is enabled. After the transfer starts, this field is decreased automatically after each successful data packet transmission.
18:7	Reserved	Must be kept at reset value.

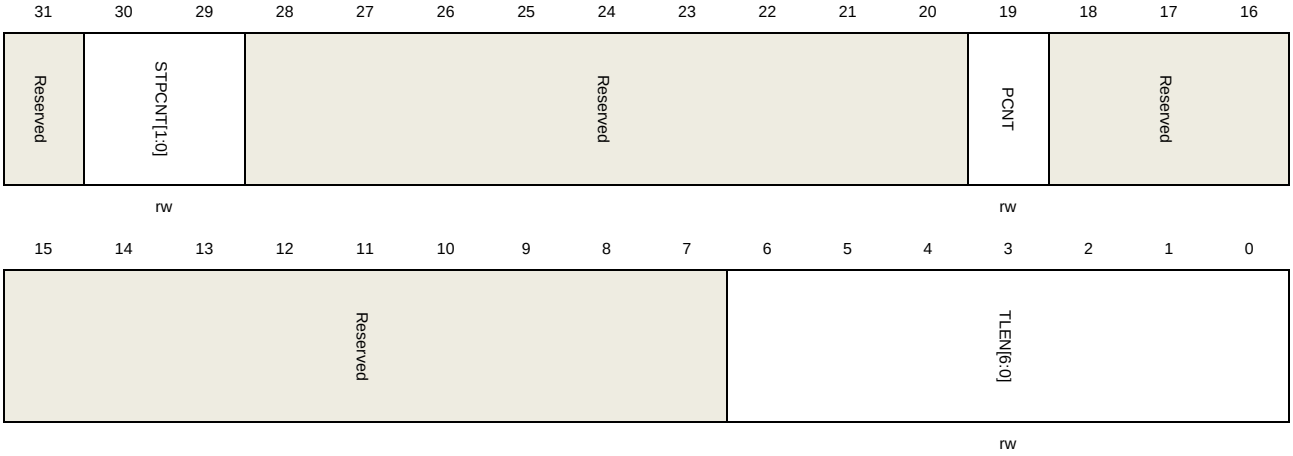
6:0	TLEN[6:0]	Transfer length This field is the total data bytes of all the data packets desired to be transmitted in an IN transfer. Program this field before the endpoint is enabled. When software successfully writes a packet into the endpoint's Tx FIFO, this field is decreased by the byte size of the packet.

Device OUT endpoint 0 transfer length register (USBFS_DOEP0LEN)

Address offset: 0x0B10

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



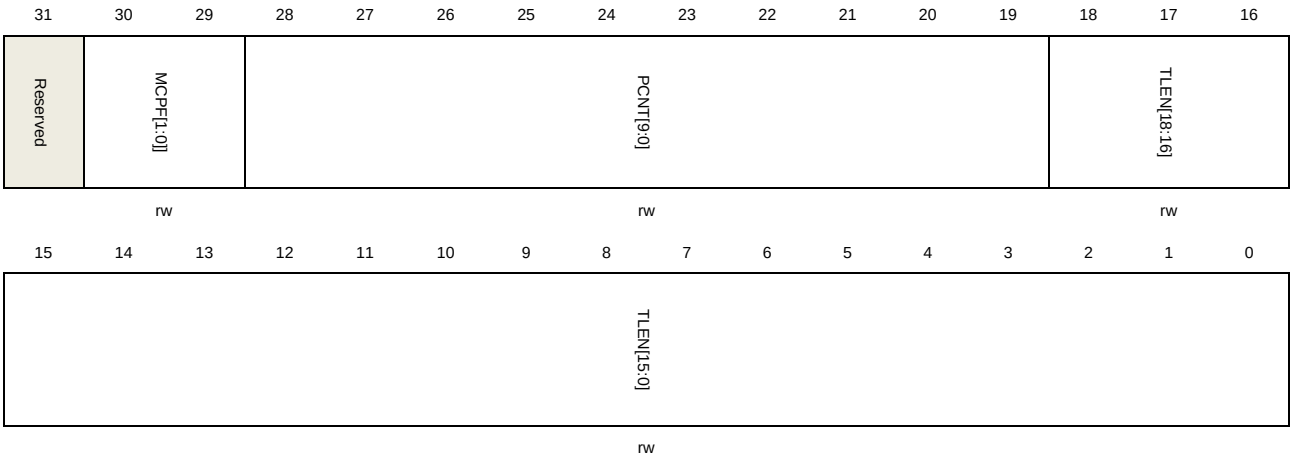
Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30:29	STPCNT[1:0]	SETUP packet count This field defines the maximum number of back-to-back SETUP packets this endpoint can accept. Program this field before setup transfers. Each time a back-to-back setup packet is received, USBFS decreases this field by one. When this field reaches zero, the BTBSTP flag in USBFS_DOEP0INTF register will be triggered. 00: 0 packet 01:1 packet 10: 2 packets 11: 3 packets
28:20	Reserved	Must be kept at reset value.
19	PCNT	Packet count The number of data packets desired to receive in a transfer. Program this field before the endpoint is enabled. After the transfer starts, this field is decreased automatically after each successful data packet reception on bus.

18:7	Reserved	Must be kept at reset value.
6:0	TLEN[6:0]	Transfer length The total data bytes number of a transfer. This field is the total data bytes of all the data packets desired to receive in an OUT transfer. Program this field before the endpoint is enabled. Each time software reads out a packet from the Rx FIFO, this field is decreased by the byte size of the packet.

Device IN endpoint-x transfer length register (USBFS_DIEPxLEN) (x = 1..3, where x = endpoint_number)

Address offset: 0x910 + (endpoint_number × 0x20)
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



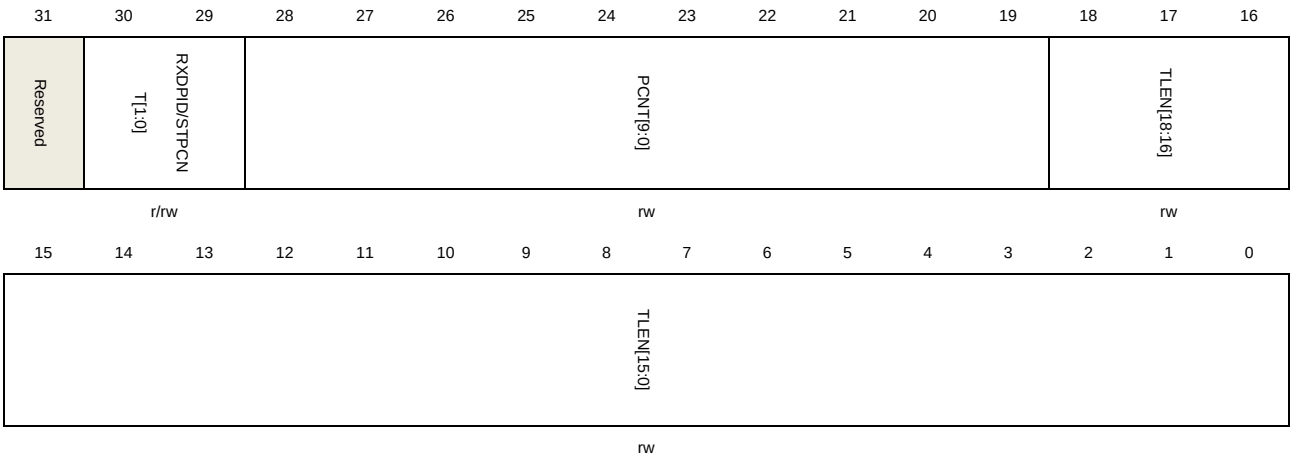
Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30:29	MCPF[1:0]	Multi packet count per frame This field indicates the packet count that must be transmitted per frame for periodic IN endpoints on the USB. It is used to calculate the data PID for isochronous IN endpoints by the core. 01: 1 packet 10: 2 packets 11: 3 packets
28:19	PCNT[9:0]	Packet count The number of data packets desired to be transmitted in a transfer. Program this field before the endpoint is enabled. After the transfer starts, this field is decreased automatically after each successful data packet transmission.

18:0	TLEN[18:0]	Transfer length The total data bytes number of a transfer. This field is the total data bytes of all the data packets desired to be transmitted in an IN transfer. Program this field before the endpoint is enabled. When software successfully writes a packet into the endpoint's Tx FIFO, this field is decreased by the byte size of the packet.

Device OUT endpoint-x transfer length register (USBFS_DOEPxLEN) (x = 1..3, where x = endpoint_number)

Address offset: 0x0B10 + (endpoint_number × 0x20)
Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31	Reserved	Must be kept at reset value.
30:29	RXDPID[1:0]	Received DATA PID (for isochronous OUT endpoints) This field saves the PID of the latest received data packet on this endpoint. 00: DATA0 10: DATA1 Others: Reserved
	STPCNT[1:0]	SETUP packet count (for control OUT Endpoints.) This field defines the maximum number of back-to-back SETUP packets this endpoint can accept. Program this field before SETUP transfers. Each time a back-to-back SETUP packet is received, USBFS decreases this field by one. When this field reaches zero, the BTBSTP flag in USBFS_DOEPxINTF register will be triggered. 00: 0 packet 01:1 packet 10: 2 packets

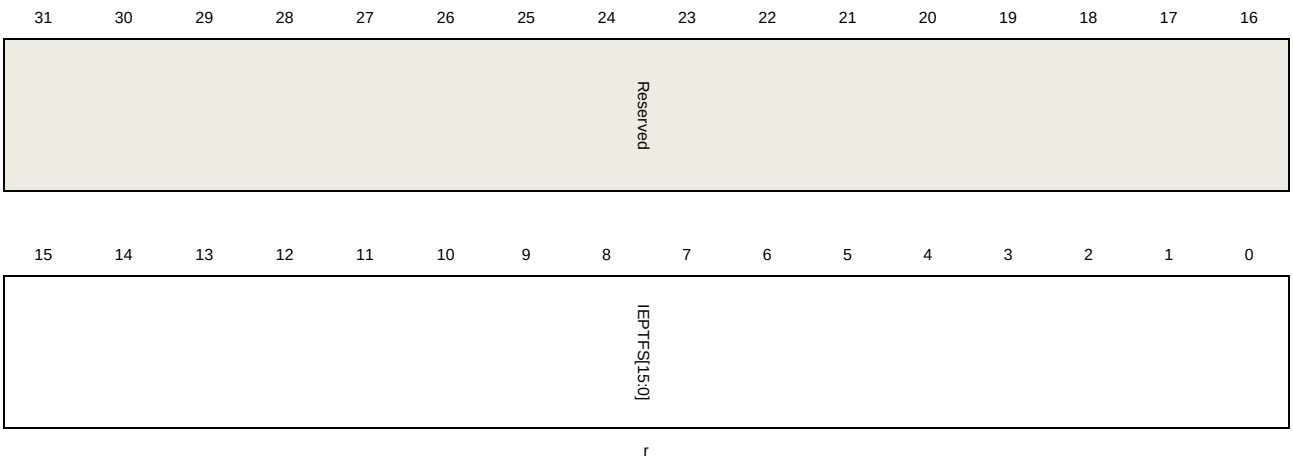
		11: 3 packets
28:19	PCNT[9:0]	Packet count The number of data packets desired to receive in a transfer. Program this field before the endpoint is enabled. After the transfer starts, this field is decreased automatically after each successful data packet reception on bus.
18:0	TLEN[18:0]	Transfer length The total data bytes number of a transfer. This field is the total data bytes of all the data packets desired to receive in an OUT transfer. Program this field before the endpoint is enabled. Each time after software reads out a packet from the RxFIFO, this field is decreased by the byte size of the packet.

Device IN endpoint-x Tx FIFO status register (USBFS_DIEPxTFSTAT) (x = 0..3, where x = endpoint_number)

Address offset: 0x0918 + (endpoint_number × 0x20)
Reset value: 0x0000 0200

This register contains the information of each endpoint's Tx FIFO.

This register has to be accessed by word (32-bit)



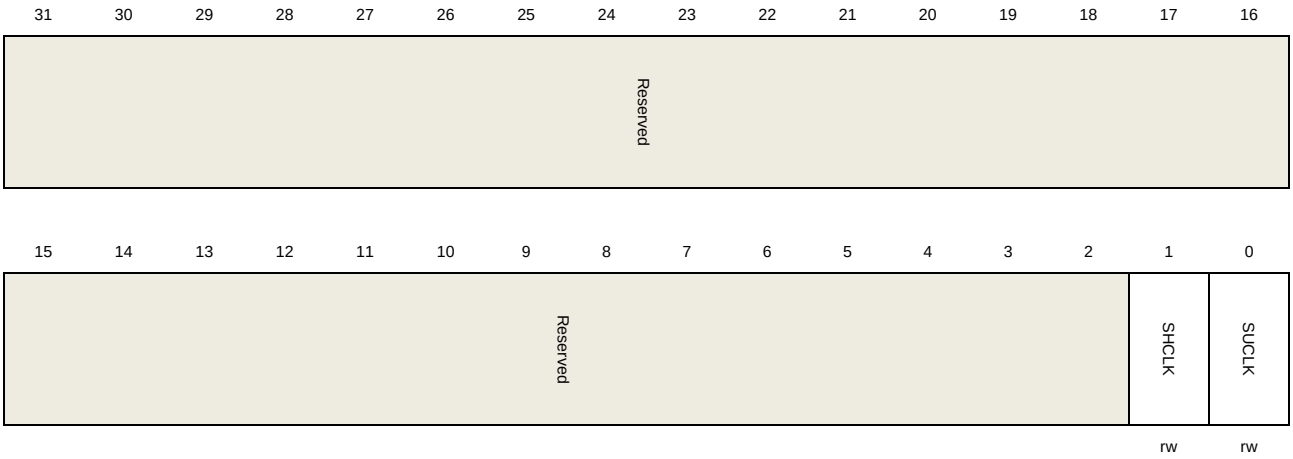
Bits	Fields	Descriptions
31:16	Reserved	Must be kept at reset value.
15:0	IEPTFS[15:0]	IN endpoint's Tx FIFO remaining space IN endpoint's Tx FIFO remaining space is in terms of 32-bit words: 0: Tx FIFO is full 1: 1 word available … n: n words available

28.7.4. Power and clock control register (USBFS_PWRCLKCTL)

Address offset: 0x0E00

Reset value: 0x0000 0000

This register has to be accessed by word (32-bit)



Bits	Fields	Descriptions
31:2	Reserved	Must be kept at reset value.
1	SHCLK	Stop HCLK Stop the HCLK to save power. 0:HCLK is not stopped 1:HCLK is stopped
0	SUCLK	Stop the USB clock Stop the USB clock to save power. 0:USB clock is not stopped 1:USB clock is stopped

29. Revision history

Table 29-1. Revision history

Revision No.	Description	Date
1.0	Initial Release	Jul.1, 2015
2.0	Adapt To New Name Convention	Jun.5, 2017
2.1	Adapt To New Document Specification	Oct 25,2018

Important Notice

This document is the property of GigaDevice Semiconductor Inc. and its subsidiaries (the "Company"). This document, including any product of the Company described in this document (the “Product”), is owned by the Company under the intellectual property laws and treaties of the People’s Republic of China and other jurisdictions worldwide. The Company reserves all rights under such laws and treaties and does not grant any license under its patents, copyrights, trademarks, or other intellectual property rights. The names and brands of third party referred thereto (if any) are the property of their respective owner and referred to for identification purposes only.

The Company makes no warranty of any kind, express or implied, with regard to this document or any Product, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. The Company does not assume any liability arising out of the application or use of any Product described in this document. Any information provided in this document is provided only for reference purposes. It is the responsibility of the user of this document to properly design, program, and test the functionality and safety of any application made of this information and any resulting product. Except for customized products which has been expressly identified in the applicable agreement, the Products are designed, developed, and/or manufactured for ordinary business, industrial, personal, and/or household applications only. The Products are not designed, intended, or authorized for use as components in systems designed or intended for the operation of weapons, weapons systems, nuclear installations, atomic energy control instruments, combustion control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, life-support devices or systems, other medical devices or systems (including resuscitation equipment and surgical implants), pollution control or hazardous substances management, or other uses where the failure of the device or Product could cause personal injury, death, property or environmental damage ("Unintended Uses"). Customers shall take any and all actions to ensure using and selling the Products in accordance with the applicable laws and regulations. The Company is not liable, in whole or in part, and customers shall and hereby do release the Company as well as it’s suppliers and/or distributors from any claim, damage, or other liability arising from or related to all Unintended Uses of the Products. Customers shall indemnify and hold the Company as well as it’s suppliers and/or distributors harmless from and against all claims, costs, damages, and other liabilities, including claims for personal injury or death, arising from or related to any Unintended Uses of the Products.

Information in this document is provided solely in connection with the Products. The Company reserves the right to make changes, corrections, modifications or improvements to this document and Products and services described herein at any time, without notice.
